Amazon L6 Senior Supply Chain Manager — NACF

Complete interview book · Rajesh Rishiyur Chandrasekaran · Loop **Thu Oct 29** & **Fri Oct 30** (PDT) · 1419 pages · bookmarked · built Oct 30 9:28AM PDT

> **One file, everything.** Today's packets are **Part A** (Fri Oct 30). Thursday interviews are **Part B** for reference. Open the PDF bookmark/outline pane to jump. Start each packet at its **5-minute cram sheet** and **Question → Story router**.

Two-day schedule

When	Status	Interviewer	Packet
Thu Oct 29 · 10:00am PDT	**DONE**	Snigdha Tripathy	Hiring Manager · NACF Supply Chain
Thu Oct 29 · 12:00pm PDT	**DONE**	Ryan Hoerger	Transfer / Placement Analytics
Fri Oct 30 · 10:00am PDT	**TODAY**	Rocky Goforth	Infrastructure **and** Bar Raiser
Fri Oct 30 · 11:00am PDT	**TODAY**	James Cabreros	Sr Mgr Supply Chain · placement architecture
Fri Oct 30 · 12:00pm PDT	**TODAY**	Venkata Josyula	Principal PM FBA · product + behavioral

READ THIS FIRST — order for Fri Oct 30

1. **Loop allocation matrix (A0)** if it is in this build — know which stories belong where.
2. **Rocky 10:00 (A1):** program-management packet → UDC/Canada pack → bar raiser bank → S/4 end-to-end backup.
3. **James 11:00 (A2):** Cabreros process / placement-architecture packet — cram sheet + router first.
4. **Venkata 12:00 (A3):** Josyula bar raiser STAR + extra stories — rehearse 20-second openers.
5. **Thu packets (Part B)** only if you need to reconcile something you already said.

Where everything is (page ranges computed at build time)

§	Section	Pages	#	One-line description
PART A — Fri Oct 30 — TODAY (read these first) · pp 4–286				
A0	Loop allocation matrix	4–21	18	Who owns which stories across the loop — read first if present.
A0b	Apple workbook delta (all three interviewers)	22–41	20	Part 0 how I run a program, failures G1-G3, Apple-only stories, resume map, numbers check.
A1	Rocky Goforth · Fri Oct 30 · 10:00am PDT (Infrastructure + Bar Raiser)	42–191	150	Program-management packet, UDC/Canada stories, bar raiser bank, then S/4 depth.
A2	James Cabreros · Fri Oct 30 · 11:00am PDT	192–248	57	Process / placement-architecture STAR

	(Sr Mgr Supply Chain · placement architecture)			packet for the peer interview.
A3	Venkata Josyula · Fri Oct 30 · 12:00pm PDT (Principal PM FBA · product + behavioral)	249–286	38	Bar raiser STAR packet plus extra behavioral stories.
PART B — Thu Oct 29 — DONE (reference only) · pp 287–537				
amazon-nacf-panel-1-tripathy-kimi-k3.pdf	Snigdha Tripathy · Thu Oct 29 · 10:00am — DONE	287–407	121	Hiring manager packet — cram sheet + router first.
amazon-nacf-panel-1-tripathy-gfiber-addon-kimi-k3.pdf	Snigdha Tripathy · Google Fiber add-on (Thu Oct 29)	408–408	1	Four design-case add-on stories for the hiring-manager interview.
amazon-nacf-panel-2-hoerger-kimi-k3.pdf	Ryan Hoerger · Thu Oct 29 · 12:00pm — DONE	409–537	129	Transfer / placement analytics packet.
PART C — Backup bench — earlier packet versions · pp 538–782				
amazon-nacf-panel-3-goforth-kimi-k3.pdf	Earlier Rocky packet (math-heavy v2)	538–617	80	Earlier Rocky packet (math-heavy v2)
amazon-nacf-panel-4-lan-kimi-k3.pdf	Zhaowen Lan peer packet (superseded by Cabreros)	618–711	94	Zhaowen Lan peer packet (superseded by Cabreros)
amazon-nacf-panel-5-josyula-kimi-k3.pdf	Earlier Josyula packet (math-heavy v2)	712–782	71	Earlier Josyula packet (math-heavy v2)
PART D — Reference — read the night before / deep backup · pp 783–1419

amazon-l6-scm-loop-packet.pdf	L6 SCM loop packet	1210–1302	93	L6 SCM loop packet
amazon-nacf-sr-scm-packet.pdf	Sr SCM NACF packet	1303–1419	117	Sr SCM NACF packet

Read this once — rules for the numbers

Distilled from the line-by-line check of every story against your Apple workbook, the source documents and the Amazon master.

Basis labels. Every number carries one: *record* / *record-from-docs* (a document or the Apple workbook backs it), *user anchor* (from your earlier packet only — confirm from memory before saying it), *modeled* / *illustrative* (your arithmetic or a teaching example — say “in the model” / “in an illustrative lane”).

1. **Never say “50x”.** Flexport Shipment Visibility is **9.7× (7 → 68 customers)**; the 170 MAU figure and 32,000 shipments are *targets*, not results.
2. **Walmart stories (S19–S21) and all Google Fiber / E-series stories are DESIGN CASES.** Say “I designed / in the model / here is how I would run it”. Your lived Walmart-theme record is Apple chapter F4.
3. **Lanes:** “a thousand lanes were asked; 597 first”. Never “400+ lanes”.
4. **Flexport cost-to-serve:** “$0.66 to $0.03, about 95%”. **FF App:** “about $5M avoided”, said once; the April 2022 launch was the import-side app.
5. **Dollar nouns:** “$2.5M” and “$1.5M” each mean several different things — always say what the number is the first time.
6. **S14** $10M won is not savings; **S16** >$100K is *priced*, not saved; S11 ~$1.5M pre-production is separate.
7. **Sephora RF devices:** “hundreds of devices”, device test before training, training +1.5 weeks, date held. Never quote a multiplier.
8. **Systems count:** “about a dozen systems”; six sites (never “six NA sites”); finished-goods grain only — no BOM explosion stories.
9. **Planner collaboration +50%** (not “planner effort −50%”). Program timeline: “within a quarter”.
10. **Yellow “VERIFY” tags** mark the few facts that exist in none of your files — use the printed safe sentence if you cannot confirm them from memory.

If asked “what’s your source for that number?” — “That’s from the program dashboard / my own model — the figure I’d stand behind is X.” Each story has the exact sentence in its SAFE-SAY box.

PART A0 · PHASE 1 · CROSS-LOOP ALLOCATION

Amazon NACF
Master Story Inventory & Loop Allocation

Rajesh Rishiyur Chandrasekaran · Friday, October 30, 2026 (PDT)

10:00 · Rocky Goforth — Amazon Infrastructure + Bar Raiser: deployment, cadence, stakeholder leadership, cost versus speed.

11:00 · James Cabreros — placement/configuration architecture: process redesign, policy governance, sequencing, self-service.

12:00 · Venkata Josyula — Principal PM, FBA + Bar Raiser: product judgment, customer mechanisms, LP depth.

Debrief rule: one primary owner per story. A second interviewer may receive only a materially different facet, with the shared facts unchanged.

Already spent Thursday: S/4HANA/ISM; FF App estimation; Shipment Visibility; safety stock; 200-lane analysis. Do not lead with these for Rocky or James. Shipment Visibility remains available to Venkata as an explicitly planned product story.

Phase-1 checkpoint. The six worker packets were still arriving. Rocky BR ended after R2 and James after J3 when this edition was frozen. “Unused” therefore means no standalone full STAR in the six named in-flight packets at this checkpoint. Phase 2 must re-read all final files.

Corpora read: Amazon master S1–S21/E1–E12; Google Fiber master v8; Apple PM III workbook v11 including failures; earlier Amazon loop/NACF packets. Basis vocabulary: record · record-from-docs · user anchor · modeled · illustrative.

Read this first — allocation in sixty seconds

INTERVIEWER	OPEN	THEN	FAILURE	DO NOT SPEND
Rocky	S2 UDC dual inventory: about a dozen systems, ~30 build tracks, 15 months	S18 RP→JDA; S5 council; Locus; A5 launch gate	G2 RF-device dependency	S11, S12, S10, S15, S13 as primaries
James	S17 carrier-bid process or S10 Austria if Venkata has not spent it	S15 governance; A4 one truth; E8/E9 explicitly as design cases	G3 security review or G1 load criteria	Walmart designs as delivered; Thursday's S1/S3 family
Venkata	S11 Shipment Visibility product launch: 7→68 customers, 9.7×	S14 trust; S16 ownership; S9 scale; S13 crisis; I1 AI product	G1 UAT concurrency miss	S18 full telling; S15 if James has already used it

Five facts to hold: S11 is 7→68 customers (9.7×), and 32,000 shipments was a target. S9 is a thousand-lane program with 597 carrying 80% of spend first. S18 uses "hundreds of RF devices"; training moved 1.5 weeks and go-live held. S14's $2.5M is order value and its $10M is initiative won. S16's six-figure annual value was priced, not claimed as realized savings.

A · Master story inventory

Location codes: RPM Rocky PM planned · RBR Rocky Bar Raiser checkpoint · UDC dual-inventory/Canada planned · J James checkpoint/planned · VM Venkata main/current · VX Venkata extras planned. “Today” means Thursday’s completed interviews. Apple and earlier-loop aliases are shown because the request was chapter-complete; aliases are not new achievements.

C · Ranked unused / underdeveloped additions

RANK	STORY	WHY ADD IT NOW	BEST OWNER	QUESTION TYPES
1	A4 apples-to-apples decommission	Real product retirement and one-truth governance; not a standalone STAR in the six worker packets.	James	Are Right Q3; Dive Deep Q2; Ownership Q4
2	A5 hundred-container launch gate	Concrete readiness proof with honest imperfection; stronger than another architecture answer.	Rocky	Highest Standards Q4; Deliver Results Q2
3	L22 Customs/FFA ownership	Direct match to James's centralized-policy and cross-team boundary work; primary document exists.	James	Ownership Q3; Earn Trust Q3; Simplify Q1
4	B3 compressed dual-program go-live	Resource collision and speed/cost trade-off for an infrastructure leader.	Rocky	Bias Q1; Deliver Results Q1; Earn Trust Q5
5	I1 LLM triage agent	Hands-on product/AI example with an eval contract and explicit unit economics.	Venkata	Invent Q1; Frugality Q1; Learn Q2
6	L25 interface-study reversal	A rare clean "I changed my mind" story; useful only with conservative secondary-source wording.	James	Are Right Q4; Frugality Q4; Dive Deep Q3

ADD-ON 1 · A4 — Apples to apples before decommission REAL

Best owner: James · **LPs:** Are Right, A Lot · Dive Deep · Ownership · **Headline:** 79 legacy customers, $185,892 ARR and 294,581 annual containers received a segment path (record-from-docs).

20-SECOND VERSION

"Leadership was comparing our 25% reliability with a competitor's 63% on unlike source mixes. I normalized both to the same basis; the competitor re-scored to about 27%, exposing measurement—not product—as the immediate gap. I then assigned all 79 legacy customers a destination and retired the duplicate truth while improving reliability to 90% against an 80% north star."

S — Situation. At Flexport, the new visibility product was being judged at 25% schedule reliability against a competitor's 63%, while a legacy source still billed 79 customers and $185,892 in annual recurring revenue. The source mixes were unlike, yet the comparison could have written off the new product and preserved two competing truths.

T — Task. I owned the retirement risk: establish an honest comparison, expose any residual product gap, and give every legacy customer an explicit path rather than letting decommission drift across another planning cycle.

A — Action. I put decommission at the top of the risk register with an owner, mitigation and date. I rebuilt the benchmark on identical sources; on that basis the competitor's 63% re-scored to about 27% versus our 25%. I showed the old dashboard's defenders that their figure was valid on its own basis, then changed the basis rather than attacking the team. I did not stop at normalization: it also exposed variance of sixteen days versus eight as the real gap, so I secured six months for source additions. In parallel, I segmented all 79 customers into migrate, white-label or cancel, with one canonical reliability definition and one executive forum signing both the improvement and retirement plans.

R — Result. The 79-customer legacy base—294,581 annual containers—received a disposition, the duplicate truth retired, and reliability reached 90% against an 80% north star after source work. Leadership could now separate measurement correction from product improvement. The durable mechanism was "reconcile before compare."

TRADE-OFF I MADE: I retired $185,892 of legacy ARR rather than preserve a small revenue stream that forced two products and two scoreboards. Normalization bought time; it did not substitute for the six months of product work.

FAILURE / LEARNING: I should have established the canonical-source rule before the first executive comparison. Once dashboards have constituencies, a cheap definition becomes an expensive negotiation.

Are Right, A Lot: I changed the decision by making both products use the same evidence.

Dive Deep: I exposed the remaining variance gap instead of using normalization only to flatter us.

Ownership: every customer received a destination and date.

SAFE-SAY: "The transition document records 79 customers, $185,892 of annual recurring revenue and 294,581 annual containers. The 90% result is the workbook record; the normalized comparison is about 27% versus 25%."
If asked for source: "The Crux transition RAPID and my 2022 product-management record, reconciled in Apple workbook v11 A4."

Was normalization spin?

No. It cut both ways: it removed the false 63-versus-25 alarm and exposed the unfavorable sixteen-versus-eight-day variance. That residual drove the six-month backlog.

What was yours versus the team's?

I rebuilt the comparison, wrote the one-source rule and set the sequence. Engineering added sources; transition owners built the customer paths with me.

B · LP × interviewer allocation

Each cell is **PRIMARY / backup — landing number**. The question column uses the AIQB's wording (lightly shortened only where marked with an ellipsis). No story is primary for two interviewers in this matrix.

LP + AIQB QUESTION	ROCKY	JAMES	VENKATA
Customer Obsession Q3: "anticipate a customer need…they didn't know they needed"	S2 / A5 — +15% efficiency	A4 / S17 — 79 customers	S11 / S14 — 7→68
Ownership Q3: initiative benefiting company/customers that no group owned	S18 / S5 — 2 DCs, 8 months	L22 / S17 — 15 work items	S16 / S14 — 4 systems→1
Invent and Simplify Q1: "complex problem…simple solution"	S5 / C2 — one council gate	S17 / L22 — ~6→~3 weeks	I1 / S16 — $25→$0.40
Are Right, A Lot Q4: bad decision; impact; learning; application	G2 / S4 — training +1.5 weeks	A4 / L25 — ~27% vs 25%	G1 / S16 — 2 days before sign-off
Learn and Be Curious Q2: work outside comfort; build expertise; outcome	S18 / C3 — 3 mocks	S10 / E9 — ~55%→99%	I1 / S9 — 100% citations
Hire and Develop the Best Q4: coaching; what started it; outcome	S2 / S18 — ~30 tracks	S15 / C2 — 20 people	S9 / G1 — 25 locations
Insist on Highest Standards Q4: decision between standards and delivery	A5 / G2 — 500 in 20 min	S10 / E8 — 99% data gate	S11 / G1 — 86% tracked, named gap
Think Big Q1: opportunity to do something bigger than initial focus	S2 / S5 — one omni facility	S10 / S17 — 25 locations	S9 / S11 — 1,000 lanes
Bias for Action Q1: calculated risk where speed was critical	B3 / C3 — <4 weeks	S17 / E9 — one live parallel run	S13 / S11 — 4 AM bridge
Frugality Q4: trade-offs between quality and cost	S18 / B3 — ~3% under budget	L25 / S17 — $42K study	I1 / S16 — 98% unit-cost cut
Earn Trust Q3: influence a peer with a differing opinion	S5 / G2 — sign-off before build	S15 / A4 — cadence adopted without mandate	S14 / S16 — ~$2.5M order value
Dive Deep Q2: dig deep to root cause	C2 / A5 — 836 rows	S10 / A4 — 3 years of history	S16 / G1 — 60%→90%
Have Backbone; Disagree and Commit Q1: strongly disagreed with manager or peer	S5 / B3 — one architecture decision	L22 / S15 — 12 export + 3 import	S14 / S9 — transparent correction
Deliver Results Q1: important project under a tight deadline	S18 / B3 — 8 months	S10 / S17 — within a quarter	S13 / S11 — 99% fill
Earth's Best Employer Q5: compassion in a high-pressure situation	G2 / B3 — protected scarce SME windows	S15 / G3 — skeptics authored the gate	G1 / S16 — owned miss, no blame
Success and Scale Bring Broad Responsibility Q2: changed a decision due to unintended customer consequences	S2 / C3 — throttled automation by zone	A4 / S4 — retired two truths deliberately	S11 / S9 — held a wave one week

Clash detector — resolve before 10:00

COLLISION	WHERE IT APPEARS	RESOLUTION
S10 Austria	RBR R1 + current VM primary	Give James the full process-improvement story. Venkata uses it only if James did not; otherwise use S9.
S13 Cyber Monday	RPM bench + James Manhattan plan + VM primary	Venkata owns the full crisis STAR. Rocky may cite only the heartbeat mechanism; James skips it.
S15 agile governance	RPM bench + James plan + VM primary	James owns people/change governance. Venkata uses I1 or S9 for the relevant LP.
S18 migration	RPM primary + VM recut	Rocky owns the full program. Venkata may mention only “published tolerance before mock one” if probed.
S11 Shipment Visibility	Thursday telling + Rocky references + VM planned	Venkata gets the product/launch facet by explicit exception. Rocky and James do not retell it.
S14 discrepancy	RPM/James potential Manhattan + VM primary	Venkata owns trust/transparency. Others use S5 or A4.
G1 failure	RBR and VM full failure arcs; James may use load criteria	Venkata owns full failure. James uses G3; Rocky uses G2.
Walmart S19–S21	J1–J3 and VM bench	James alone uses them, always bannered DESIGN CASE and paired with a lived analog.
UDC-B1 / UDC-B3	New UDC/Canada pack tells the same UDC base to Rocky and James	Rocky owns the end-to-end UDC program. James may use only Canada node configuration or the 44-row governance mechanism, explicitly saying it is the same UDC program.

ADD-ON 2 · A5 — A hundred containers before a customer REAL

Best owner: Rocky · **LPs:** Insist on Highest Standards · Deliver Results · Dive Deep · **Headline:** 500 containers in 20 minutes at 99.6% connectivity; dry run 100% processed and 86% tracked (record-from-docs).

20-SECOND VERSION

"I replaced a launch date with two evidence gates. A hundred real containers carried seven checks and every miss had a defect ID. The performance proof processed 500 containers in 20 minutes at 99.6% connectivity; the end-to-end run exposed an 86% tracked gap, which I shipped only as a named, owned workstream. Both checkpoints passed and the first pilot launched on schedule."

S — Situation. Before Flexport's first paying 4PL visibility customer could launch, leadership wanted a date, but the product's promise—trustworthy tracking—had not been proven through a representative production path. If the date became the test, the customer would absorb our defects.

T — Task. I owned the readiness verdict. I had to define business and technical gates before decision week, create evidence that joined defects to real containers, and balance an imperfect tracking gap against the customer and schedule cost of indefinite delay.

A — Action. I published two go/no-go gates, both required to pass. I made a hundred real containers the UAT spine, with checks for creation, subscription, returned data, route, milestones, exceptions and webhooks. Every mismatch carried a Jira ID, so clusters—not anecdotes—burned down. I set an 80% minor-or-no-issues bar before customer-facing UAT and used named shadow accounts first. The weekly data-quality bar rose through the final four weeks, and a thin sample could not print green. I also required load evidence: 500 containers in 20 minutes at 99.6% connectivity. The end-to-end run processed everything but tracked 86%; I refused to hide that fourteen-point gap, assigned its causes and owner, and put it on the launch dashboard.

R — Result. Both checkpoints passed, defect clusters reached zero before customer exposure, and the first pilot launched on schedule. The unresolved tracking gap shipped measured and owned, not as a surprise. Decision week became a readout of pre-published evidence rather than a negotiation over the date.

TRADE-OFF I MADE: I chose evidence with a visible imperfection over either perfection-driven delay or an unmeasured launch. The cost was carrying a named follow-on workstream and defending 86% tracked in public.

FAILURE / LEARNING: I named the processed-versus-tracked gap too late. I now put the gap on the dashboard from the first test cycle.

Highest Standards: a date could not substitute for two published gates.

Deliver Results: the pilot launched on schedule after both gates passed.

Dive Deep: each container-level failure mapped to a defect cluster and owner.

SAFE-SAY: "The source records 500 containers in 20 minutes at 99.6% connectivity and an end-to-end run at 100% processed, 86% tracked. That was launch evidence, not a steady-state scale claim."
If asked for source: "The launch-status guide, product-testing approach, hundred-container CSV and November 2021 program status."

Why launch with one in seven not tracked?

The causes were known, bounded and owned. Delay would not remove weak-lane coverage; putting the gap on the dashboard created an accountable improvement path.

What was yours?

I designed the gates, UAT spine and decision week. Engineering ran the harness and fixed defects; QA co-owned test execution.

ADD-ON 3 · L22 — Customs and FFA: one boundary, fifteen work items REAL · DOC-BACKED

Best owner: James · **LPs:** Ownership · Earn Trust · Invent and Simplify · **Headline:** 15 planned 2023 work items—12 export and 3 import—mapped to one ownership agreement (record-from-docs).

20-SECOND VERSION

"Customs Platform and Freight Forwarding Applications overlapped on fifteen work items. I turned the argument into a row-by-row ownership proposal: domain decision, operational execution, data owner, API and exception. The final meeting assigned FFA all work items except ISF filing, with explicit APIs and shared cost-to-serve goals where the seam remained."

S — Situation. In 2022, Flexport's Customs Platform and Freight Forwarding Applications teams overlapped on customs-declaration work, especially AMS. The next-year roadmap contained fifteen work items—twelve export and three import—and ambiguous ownership would create duplicate builds, dependency queues and inconsistent status for operators.

T — Task. I needed to produce a durable boundary that let each organization stay in its domain while preserving an end-to-end operator flow. Neither team reported to me, and a slogan such as "Customs owns customs" was too vague to configure.

A — Action. I decomposed the roadmap work item by work item and wrote the operating decision beside each: who plans, who executes, who owns the backend and data model, which actions remain offline, what API is required, and where status returns. I separated customs-domain planning and filing from FFA's operational execution of moving cargo. For disputed seams—EAD, port filing, ISF and AMS—I documented current capability, future capability and interim ownership instead of pretending the target architecture already existed. I used the same sheet in the final cross-team meeting, captured unresolved decisions explicitly, and tied shared seams to shared cost-to-serve goals. A future capability never erased the named interim owner.

R — Result. The November 3 ownership agreement assigned FFA all work items except ISF filing. AMS used Customs APIs for create, amend, query and delete; ISF retained a query dependency; AES aligned on integration. The roadmap now had one accountable owner per row and explicit interfaces where ownership crossed organizational lines.

TRADE-OFF I MADE: I chose a pragmatic interim boundary with some offline work over waiting for a perfect platform split. That preserved delivery but left API dependencies to govern.

FAILURE / LEARNING: The first framing was organization-based and too abstract. The agreement emerged only after I moved to work-item and state-transition grain.

Ownership: I took the seam no organization could solve alone.

Earn Trust: capability gaps and unresolved rows stayed visible.

Invent and Simplify: one row-level matrix replaced a domain argument.

SAFE-SAY: "The proposal states fifteen 2023 work items: twelve export and three import. The final agreement says FFA owned all except ISF filing; it does not claim a quantified business outcome."
If asked for source: "Customs Platform / FFA Ownership Proposal, pages 1 and 14."

Did you decide the boundary yourself?

No. I created the decision artifact and drove convergence; the accountable leaders signed the ownership agreement.

How did you know it worked?

The documented result is decision closure and explicit interfaces. I would not invent a defect or cycle-time reduction that the source does not report.

ADD-ON 4 · B3 — Two programs, one engineering team REAL

Best owner: Rocky · **LPs:** Bias for Action · Deliver Results · Earn Trust · **Headline:** strategic go-live pulled forward one month; compressed program landed inside four weeks; Rajesh's program held its date (record).

20-SECOND VERSION

"Leadership pulled a strategic launch forward one month and shared my engineers across two programs. I stopped arguing priorities and ran one RAID log, one 45-minute forum and one blocker ruler. True blockers used written onsite-to-offshore handoffs. The compressed launch landed inside four weeks and mine held its original date."

S — Situation. At Flexport, leadership pulled a strategic go-live forward by one month and reassigned engineers from my program. Two programs now shared one team and one immovable business-adoption window. A rushed technical launch that the floor rejected would simply move the failure downstream.

T — Task. I had to land both programs without asking people to work around the clock, make the resource collision visible to leadership, and protect business adoption rather than optimize only for code complete on paper.

A — Action. I ran both programs as one operating system: one RAID log, one 45-minute daily forum and one ruler—true blocker, non-blocker or requirements gap. Within a week, that classification removed most false blockers from engineering's queue. True blockers entered a two-pass war room: onsite and offshore teams handed off in writing, creating round-the-clock issue velocity without a person working a full day. I published both burn-downs together and escalated only priced choices, never complaints. Every same-day escalation stated what option A cost and what option B cost. The go/no-go read the agreed blocker floor rather than the calendar. I also wrote a ten-step quick-reference guide for the floor so adoption did not become the hidden schedule risk.

R — Result. The pulled-forward program landed inside four weeks; my original program held its committed date; the business adopted on time. The primary record supports the monthly value-at-stake rate, but I lead with the dates and the operating mechanism rather than a derived cumulative dollar.

TRADE-OFF I MADE: I accepted a heavier, tightly bounded daily cadence to preserve both dates. I rejected invisible overtime and serial priority fights. The cost landed on a managed team calendar.

FAILURE / LEARNING: The floor guide shipped only the week before cutover. Under compression, documentation dies first; I would draft it when the collision begins.

Bias for Action: one forum and a common ruler were operating in days.

Deliver Results: one program landed in under four weeks and the other held date.

Earn Trust: both burn-downs and resource consequences stayed public.

SAFE-SAY: "The record says the launch moved one month earlier, the compressed program landed inside four weeks, and mine held date. I do not lead with a multiplied dollar."
If asked for source: "My 2022 ambiguity record and Apple workbook v11 B3."

Did you oppose leadership's decision?

I made the collision and value visible, then committed. My disagreement was with hidden cost, not with the chosen priority.

What was yours?

The shared RAID, forum, blocker taxonomy, escalation framing and floor guide. Engineers built and fixed; operators adopted.

ADD-ON 5 · I1 — LLM triage with a balance sheet and contract REAL BUILD

Best owner: Venkata · **LPs:** Invent and Simplify · Frugality · Learn and Be Curious · Dive Deep · **Headline:** cost per triaged incident $25→$0.40, a 98% cut, with 100% citation coverage and accuracy held on the eval set (record).

20-SECOND VERSION

"I built an incident-triage agent end to end, but the first version cost $25 per incident—a demo, not a product. I created a graded eval set, enforced 'no citation, no proposal,' and routed easy classes to smaller models. Cost fell to $0.40, 100% of proposals cited evidence, and accuracy held on the eval set."

S — Situation. I independently built an LLM agent to read operational incidents, classify them and propose the first action. The naïve version worked, but at $25 per incident it was an expensive demo. An uncited proposal would also force an operator to redo the analysis, destroying trust.

T — Task. I owned the stack and the product bar: preserve triage accuracy, make every proposal auditable, and bring unit cost below one dollar before treating the tool as operational.

A — Action. I built the eval set before optimizing the agent: historical incidents with known-correct outcomes, graded and rerun after every prompt, model or routing change. I established a hard contract—no citation, no proposal—binding each recommendation to ticket evidence and a runbook line. I then treated inference cost like a program budget. A cheap classifier routed common, easy incident classes to smaller models; only the hard tail reached the expensive model. I rejected the cheaper alternative of removing evidence because that would transfer verification cost to operators. I tracked one dashboard with three measures: eval-set accuracy, citation coverage and cost per incident. I built the Python, FastAPI, tool-use and SQLite path myself, so I could isolate each cost and failure mode rather than negotiate across owners.

R — Result. Cost fell from $25 to $0.40 per triaged incident—a 98% reduction—while accuracy held on the eval set. Citation coverage reached 100%, and the $0.40 outcome cleared the sub-dollar operations bar without transferring evidence-checking work back to the operator.

TRADE-OFF I MADE: I chose tiered routing over one premium model for every incident. The eval set paid the complexity cost by proving which classes were safe to route cheaply.

FAILURE / LEARNING: I did not freeze the first eval-set version early enough. A growing baseline made early accuracy claims harder to compare; I now version the contract before tuning.

Invent and Simplify: the router reserved expensive reasoning for the hard tail.

Frugality: unit cost fell 98% against a stated bar.

Learn and Be Curious: I learned by building and instrumenting the full stack.

SAFE-SAY: "This was my independent build. The recorded result is $25 to $0.40 per triaged incident, with accuracy held on my graded eval set and 100% citation coverage."
If asked for source: "My project record, carried into Apple workbook v11 I1; it is not an employer production claim."

Is this just another demo?

A demo has no regression contract or unit economics. This one gated every change on an eval set and engineered to a sub-dollar bar.

Where would it break at Amazon scale?

Data sensitivity, eval maintenance and volume economics become programs. I would require access review and production monitoring before deployment.

ADD-ON 6 · L25 — The interface study I first refused REAL · SECONDARY-SOURCE CAUTION

Best owner: James · **LPs:** Are Right, A Lot · Frugality · Dive Deep · **Headline:** 17 interfaces narrowed to 2 critical usages; $42K study funded with $25K contingent (secondary packet record; verify provenance).

20-SECOND VERSION

"A partner requested a $42K interface study. I first refused because seventeen interfaces sounded like broad documentation. Evidence then showed two usages sat on the critical path. I reversed my decision, funded the study with $25K contingent on findings, and narrowed the scope to those two usages. The lesson was to be frugal about scope, not evidence."

S — Situation. During the Sephora inventory program, a partner requested a $42K study across seventeen interfaces. My first reaction was no: the request looked like paying to document everything when only a subset could affect the launch.

T — Task. I had to protect scarce program funds without creating a blind spot on the critical path. More importantly, I had to be willing to reverse my own decision if the evidence changed the risk classification.

A — Action. I asked for a usage-level dependency map instead of a generic interface list: which business event crossed each interface, which go-live gate depended on it, whether a mock exercised it, and what failure would look like. The map showed that two usages were critical, not all seventeen. That changed the decision. I went back to the sponsor, stated that my initial refusal had treated interface count as a proxy for risk, and recommended funding the $42K study with $25K contingent on what the first pass found. I narrowed the charter to the two critical usages and required the study to produce test cases and an owner—not a shelf document. I preserved a visible stop decision if evidence did not support further work.

R — Result. The study was funded on a gated basis and the broad seventeen-interface concern became two testable critical usages with named owners and gates. The value of the story is the judgment reversal and scoped evidence; the source does not support a separate delivered-savings claim.

TRADE-OFF I MADE: I spent $42K to reduce a launch blind spot but kept $25K contingent. I rejected both a blanket refusal and an open-ended study.

FAILURE / LEARNING: My first no was too fast. I confused a large inventory with low marginal value. I now classify usage criticality before pricing assurance.

Are Right, A Lot: I reversed my own call when the dependency evidence changed.

Frugality: scope and follow-on funding were gated.

Dive Deep: business-event usage replaced interface count.

SAFE-SAY: "An earlier loop packet records seventeen interfaces, two critical usages, a $42K funded study and $25K contingent. I would verify the original artifact before using the dollars; the safe story is that I reversed a refusal after usage-level evidence."
If asked for source: "The earlier Amazon loop packet, story S25; the primary artifact is not in the current source set."

Why include a story with secondary provenance?

Only as a backup after verification. The behavior is useful, but I will not upgrade packet figures into primary-record facts.

What if Rajesh cannot verify it?

Drop the dollars and say: "I narrowed a broad interface study to two critical usages and reversed my initial refusal."

VERIFY checklist and exact safe sentences

- **L25 primary artifact.** Safe: “An earlier loop packet records seventeen interfaces narrowed to two critical usages. Until I confirm the source artifact, I will describe the reversal and omit the dollar amounts.”
- **S17 cycle-time figures.** Safe: “My program anchor is about six weeks to about three; I claim no award savings.”
- **A4 ARR retirement interpretation.** Safe: “The document records the legacy revenue base; I am not claiming that the full amount was lost in one period.”
- **B3 value framing.** Safe: “I can defend the monthly per-DC rate in the program record; the strongest result is that both dates held.”
- **Earth’s Best Employer coverage.** Safe: “I did not manage a direct-report organization in these stories; my evidence is how I protected operators and SMEs under pressure.”

Phase-1 report

What the mining found. The master has enough real stories to keep designs off the behavioral path. The strongest underused records are A4's product-retirement governance, A5's launch evidence, L22's ownership boundary, B3's resource collision and I1's AI unit economics. L25 is useful only after provenance verification. The newly arrived UDC/Canada pack adds a real 99-brand cross-border plan and a 44-row node-governance mechanism; post-launch Canada outcomes remain VERIFY.

Six add-on headlines. A4: 79 customers / $185,892 ARR / 294,581 containers. A5: 500 containers in 20 minutes at 99.6%, with 86% tracked named honestly. L22: 15 work items, one signed boundary. B3: one month pulled forward, compressed launch inside four weeks, both dates held. I1: $25→$0.40 per incident, 100% citations. L25: 17 interfaces→2 critical usages, secondary-source dollars to verify.

Primary collision fixes. S10→James, S13→Venkata, S15→James, S18→Rocky, S11→Venkata, S14→Venkata; G2/G3/G1 become Rocky/James/Venkata's distinct failures.

Design discipline. S19–S21 and E1–E12 remain DESIGN CASES, never delivered results. Pair E8 with lived S15, E9 with lived S18, and Walmart promise ideas with lived F4 only if needed.

FRIDAY OCT 30 · APPLE SOURCE DELTA · SAY-ALOUD ADD-ON

Amazon NACF — Apple Workbook Delta

Rajesh Rishiyur Chandrasekaran · Rocky Goforth 10:00 · James Cabreros 11:00 · Venkata Josyula 12:00 PDT

What this is. A subtraction, not another master packet: Apple PM III workbook v11 compared with the Amazon master and the panel files present during build. It preserves the Apple-only operating framework, failure detail, probing language, and three compact stories that are not standalone stories in the Amazon master.

Three opening sentences.
1. “For fifteen years I have run programs the same way: baseline first, one scorecard, numeric gates, first-principles triage, then corrections in the same cadence.”
2. “I will be specific about what I owned, what engineering or operations owned, and whether a number is a record, a document figure, or a model.”
3. “The part of every story I care most about is what I would do differently, so please ask me that on any example.”

Freshness and allocation

Interviewer	Use first	Do not lead with
Rocky — infrastructure + Bar Raiser	G1 concurrent-load UAT failure; the five-part program framework; “test at the customer’s shape.”	S/4/ISM, Flexport estimation, safety stock, lane lead-time, or Shipment Visibility as a primary.
James — placement architecture + process	B3 two-program collision; one ruler, one forum, written handoff; process governance.	Already-used S/4/ISM, estimation, safety stock, lane lead-time; use them only as a sentence of proof.
Venkata — FBA Principal PM + behavioral	I1 triage product; customer-safe evidence; G2/G3 if asked for another failure. Shipment Visibility is allowed for the product lens.	Do not turn I1 into an employer deployment: it is an independent build.

Basis labels. record Apple v11 and/or resume; record-from-docs primary program artifact; user anchor earlier Rajesh packet only; modeled arithmetic or assumptions, not banked value. No bare dollar: always attach its noun.

Five numbers to keep exact. Customers **7 → 68 = 9.7×**; CTS **$0.66 → $0.03 per container, about 95%**; FF App **about $5M of avoided cost**, said once; RF fleet **“hundreds of devices”**; UAT **5 users × 10 scenarios, crash 2 days before sign-off**.

Primary sources: Apple_PMIII_Interview_Stories_v11_2026-08-26_7241.pdf/text; Rajesh_ChandrasekaranApple resume; Amazon master HTML; NUMBERS-RECON CANON v2; panel files present during build. All Apple page cites are PDF pages.

1 · Apple workbook map — every part and chapter

“In master” means the content is materially absorbed into that Amazon story, even if Apple’s chapter boundary disappeared. “Panel” names a current in-flight or existing interviewer packet where the angle is already developed. **APPLE-ONLY** means no standalone Amazon-master story.

Part / ID	Apple chapter, one-line job	Amazon master	Panel / status
Part 0	Opening, five-part “How I run a program,” TMAY, Why Apple, AIQB coverage.	No standalone equivalent; mechanisms distributed across stories.	**APPLE-ONLY framework**; use with Rocky and James.
A1	Shipment Visibility wave machine: calibration, six graduation criteria, 7 → 68.	S11	Josyula existing; master-primary family.
A2	WBR math: grain/date discipline, automation and cost-to-serve.	S11	Josyula / Hoerger family; exact integrity phrases remain delta.
A3	Four systems to Snowflake; BRD, frozen metrics, parallel run.	S16	Josyula S16; G3 failure remains useful.
A4	Legacy decommission: normalize unlike comparisons, then improve the residual.	S11 depth	Josyula Crux bench; not fresh as a full story.
A5	Hundred-container launch gate with bug IDs and two go/no-go checkpoints.	S11 depth	Josyula recut / master family.
B1	FF App complete arc: scope, CTS sequence, burn-up, UAT, launch.	S12	Already used today; bench only tomorrow.
B2	Cost-to-serve decision that flipped operator-first to partner-first.	S12	Already used today; one-line backbone bridge only.
B3	Two programs, one shared team, one ruler; both dates held.	**APPLE-ONLY**	Goforth bank R6 now has a full telling; allocate tomorrow’s telling to James only.
C1	UDC: live building from two systemic warehouses to one omni facility.	S2	James / UDC panels; not delta as a full story.
C2	UDC counted operating system: 836-row log, build plan, cutover.	S2 depth	James process family.
C3	Locus robots earn volume; throttle at 94% against a 98% bar.	S2	Goforth PGM / UDC family.
C4	Architecture council: pre-wire every system row; ask for three decisions.	S5	James profile match; use exact phrase only.
D1	Two DCs to JDA in eight months using gates instead of prior WMS experience.	S18	Josyula recut / James process family.
D2	Three mock cutovers; tolerance published before mock one.	S18	Josyula recut / James process family.
D3	Twenty-person team adopts four-week cadence; QA owns the gate.	S15	Josyula S15 / James process family.
E1	ISM inventory operating model: policy before configuration.	S1/S3/S4	Already told today; bridge only.
F1	Thousand-lane program phased by value and a data-quality toll.	S9	Josyula S9; count conflict—use safe wording.
F2	Routing-guide engine: measurement first, Finance-auditable savings.	S10	Goforth bank R1 / Josyula S10.
F3	Reason-coded shortage alert and forecast-accuracy program.	S6	Already told today; bridge only.
F4	Measured lane distributions and tail promise; drift-flag regret.	S8	Already told today; James uses as lived bridge.

M1	Cyber Monday 4 AM: promise-at-risk triage across three DCs.	S13	Josyula S13.
I1	Independent LLM triage agent: eval-first, citations, cost routing.	**APPLE-ONLY**	Goforth bank R7 now has a full telling; allocate tomorrow's telling to Venkata only.
G1	Failure: UAT scenarios passed; concurrency crashed two days before sign-off.	**APPLE-ONLY**	Goforth / James / Josyula failure arcs overlap; allocate full telling to Rocky only.
G2	Failure: RF script broke the training gate; effort is not impact.	S18 failure beat	James training angle / Josyula failure arc.
G3	Failure: security review found mid-build; plan access lead time.	S16 failure beat	Josyula S16 / failure arc.
Part 7	Gap scripts, rapid-fire bank, risk flags, closing integrity notes.	No standalone equivalent.	**APPLE-ONLY phrasing bank**; selected deltas below.

2 · Delta list — what Apple adds tomorrow

How to read this. Each item is an Apple-specific framework, failure detail, probing answer, or exact phrase not needed as a repeated master-story telling. “Drop-in” is the sentence to say; do not recite the analysis around it.

Rocky Goforth — infrastructure program + Bar Raiser (10 items)

RΔ1 · Part 0 — the named operating system. Baseline → one scorecard → numeric gates → root-cause triage → correction verified in cadence. Apple pp4–5.
Drop-in: “My program method is baseline first, one scorecard, numeric gates, first-principles triage, and correction verified by the same number going green.”

RΔ2 · Part 0 — exact gate test. The workbook’s sharper test is not whether a gate exists but whether it can stop work. Apple p4.
Drop-in: “A gate that cannot stop the program is decoration, so I publish the stop line before the first test.”

RΔ3 · Part 0 — red-item contract. Every red arrives with a cause, owner, and date in the same review that surfaced it. Apple p4.
Drop-in: “A red without a cause, an owner, and a date is not status; it is deferred discovery.”

RΔ4 · TMAY ownership probe. Rajesh explicitly separates program machinery from code: he wrote scorecards, BRDs, gates and cadence; engineers built product and automation. Apple p5.
Drop-in: “When I say I, I mean I built the operating system and made the cutover call; engineering built the code.”

RΔ5 · D1 — “gates instead of experience.” Rajesh had never run a WMS migration; the absence of a “trust me” shortcut made written entrance criteria load-bearing. Apple pp28–29.
Drop-in: “I had no experience shortcut to sell, so every phase had to earn entry and exit on written evidence.”

RΔ6 · D2 — rehearsal philosophy. The mock produces the runbook; the live cutover is the next rehearsal with the audience watching. Apple pp30–31.
Drop-in: “A failed mock is cheap; a failed cutover is not—the cutover should feel like the next rehearsal with a larger audience.”

RΔ7 · M1 — instrument silence. The scheduler stopped without emitting a failure, so the permanent control made absence of a heartbeat the alert. Apple pp40–41.
Drop-in: “The process was not wrong; it was silent. We made silence itself the alarm.”

RΔ8 · M1 — the reliability outcome. The next peak being uneventful is framed as an engineered result, not an anticlimax. Apple p41.
Drop-in: “The next peak ran boring, and boring is the reliability deliverable.”

RΔ9 · A3 — why the BRD was the work. The workbook answers the “you only wrote a document” probe directly: complaints become funded, buildable programs through exact specifications. Apple p11.
Drop-in: “Programs die as complaints and ship as documents; my BRD made the operating pain fundable and testable.”

RΔ10 · Part 7 — tool humility. Rajesh’s strongest instrument is the hand-built model and the shared SQL layer, not decorative BI. Apple pp46–47.
Drop-in: “I build in the tool the team reads; I am not a dashboard stylist, but I can interrogate the data underneath it.”

James Cabreros — placement architecture + process improvement (10 items)

JΔ1 · E1 — policy versus configuration. Rajesh owns the business-readable state and channel rules; ERP specialists own transaction-level configuration. Apple pp32–34.
Drop-in: “The policy is mine and the transaction codes are theirs; when they disagree, the signed policy wins and configuration changes.”

JΔ2 · F1 — exception governance. Planner overrides were preserved only with reason codes; silent workarounds were rejected because they cannot improve a rule. Apple pp34–35.
Drop-in: “Overrides with reasons are data; silent workarounds are not.”

JΔ3 · F3 — trustworthy self-service. Every alert carried the input that moved, making verification a thirty-second operator action. Apple pp37–38.
Drop-in: “A self-service decision needs a reason line an operator can check in thirty seconds.”

JΔ4 · F3 — trust as a process metric. False alarms were counted and burned down publicly instead of asking planners to “adopt” the alert. Apple p38.
Drop-in: “Trust is the residue of a low false-alarm rate; I measure it instead of asking for it.”

JΔ5 · C1 — interim architecture has an operating cost. Four months with two systems of record required every report to declare its source; Rajesh would start a reporting workstream on day one. Apple pp21–23.
Drop-in: “If migration creates two temporary truths, reporting strategy is a workstream from day one, not month three.”

JΔ6 · A4 — retire the old truth respectfully. A team accepts one canonical source more readily when its old metric is credited for exposing the problem. Apple pp12–13.
Drop-in: "I gave the old metric a dignified retirement—it became evidence for the backlog, not the loser in a dashboard fight."

JΔ7 · D2 — publish the line before the data. The quality threshold is governance only if it predates the result and can force a delay. Apple pp30–31.
Drop-in: "A tolerance negotiated after results arrive is not a tolerance; publish the line before the data."

JΔ8 · D3 — change design. "Their ceremonies, my evidence": the team authored the cadence mechanics while Rajesh published whether work actually reached QA and demo. Apple pp31–32.
Drop-in: "I traded control for adoption: they authored the ceremonies; I authored the evidence."

JΔ9 · D3 — resistance as a requirement. QA's fear of a shorter testing window became the definition-of-done they owned. Apple p32.
Drop-in: "Resistance is often a design requirement wearing a complaint; I handed QA the gate instead of arguing with the fear."

JΔ10 · Part 7 — executive decision format. One page: metric, trend, driver, ask; the answer belongs in the room and the derivation in the appendix. Apple pp47–48.
Drop-in: "The room gets the answer; the appendix gets the audit—metric, trend, driver, ask."

Venkata Josyula — Principal PM / product + behavioral (10 items)

VΔ1 · A5 — launch proof versus scale proof. The 500-container performance check answered launch readiness, not the 68-customer steady state. Apple pp14–15.
Drop-in: "A launch gate that pretends to be a scale proof is lying; ours answered launch week, and waves carried the scale proof."

VΔ2 · A4 — sequence the decision. Normalize unlike data to earn time, then improve the real residual to deserve decommission. Apple pp12–13.
Drop-in: "I normalized first to earn the time, then improved the residual to deserve it."

VΔ3 · B1 — product outcome over shipping output. Monthly operator interactions eliminated was the focus metric; features shipped was explicitly rejected as the customer outcome. Apple pp15–17.
Drop-in: "A screen shipped is a build output; an operator touch that no longer happens is a product outcome."

VΔ4 · B1 — customer translation. The internal interaction count connected to five customer-facing levers: documents on platform, reports in-app, fewer impersonations, no-touch onboarding and self-booking. Apple pp16–17.
Drop-in: "I forced the internal metric to map to what the customer felt; otherwise it was vanity."

VΔ5 · F1 — adoption is behavior change. The lane was the unit of work, but the real product change was planners trusting a guide over memory, with explainable overrides. Apple pp34–35.
Drop-in: "It looked like a data program; it was behavior change wearing a data costume."

VΔ6 · A4 — analysis that cuts both ways. Normalization removed a false gap but exposed a real variance gap; that made it analysis rather than spin. Apple pp12–13.
Drop-in: "The normalization was credible because it also exposed where we still lost; analysis that only flatters is spin."

VΔ7 · A5 — shipping a measured gap. The dry run processed 100% but tracked 86%; the gap shipped named, owned and visible rather than hidden. Apple pp14–15.
Drop-in: "I will ship a measured, owned gap before I ship a surprise; 86% tracked had a named workstream and stayed on the dashboard."

VΔ8 · F4 — product maintenance regret. The distributions launched before the drift flag; a planner found a degraded lane manually. Apple pp38–40.
Drop-in: "I shipped the insight before the self-monitor; now the drift flag ships with the first distribution."

VΔ9 · M1 — incident leadership regret. The decision log was right, but Rajesh carried the first stretch alone and should have paged the on-call engineer earlier. Apple pp40–41.
Drop-in: "The triage was right; my escalation was late. I should have paged the on-call engineer before carrying the first stretch alone."

VΔ10 · B2 — disagree without ambush. The manager saw the contrary math first and pressure-tested it with engineering for two days before the room decided. Apple pp17–19.
Drop-in: "I disagreed privately, let engineering attack the math for two days, then asked the room to ratify what survived."

3 · Apple-only story A01 — I1: the LLM triage agent

Allocation note. The current Goforth bank also contains full versions of A01, A02 and A03. They remain here because this task requires the Apple-only stories as a self-contained add-on. Do not tell them twice: A02 to Rocky, A03 to James, A01 to Venkata.

Assigned: Venkata — product judgment, evals, customer trust, unit economics. **Company:** independent build, not an employer deployment. **LPs:** Invent and Simplify · Frugality · Dive Deep · Ownership.

LP proof. Invent: routed easy and hard classes differently. Frugality: unit cost was a launch KPI. Dive Deep: graded historical outcomes before model changes. Ownership: built the stack, eval harness and operating rule himself.

60-second pitch. “I built an independent LLM triage agent and treated it as an operations product, not a demo. The naive version cost $25 per incident, and an uncited recommendation made the human repeat the work. I first graded historical incidents into an eval set, then set two release bars: the past must keep passing, and every proposal must cite the ticket and runbook. I routed easy classes to smaller models and reserved expensive calls for the hard tail. Cost fell to $0.40 per incident, a 98% reduction, with accuracy held on the eval set and 100% citation coverage. My regret is that the first eval set grew while early prompts were being judged; I would freeze and version the baseline before the first change.”

S I independently built a Python/FastAPI triage agent for operational incident queues. The naive path produced useful proposals but cost $25 per incident and could answer without a checkable chain of evidence. record

T I needed an operations-grade product: quality held on known cases, every proposal checkable, and unit cost below one dollar—without presenting it as an employer production deployment.

A I graded historical incidents with known-correct triage outcomes before changing prompts or models. I made the eval set the release gate; every prompt, model or routing change had to keep the past passing. I imposed “no citation, no proposal,” binding each action to ticket evidence and a runbook line. I then measured cost by class and routed routine classifications to small models, reserving expensive calls for the hard tail. I reviewed eval accuracy, citation coverage and unit cost together, because optimizing any one alone would create a demo, not a product.

R Cost moved from $25 to $0.40 per triaged incident—a 98% reduction—while accuracy held on the eval set; citation coverage was 100%. record The result was an independently built product with a quality contract and unit economics, not a claim of enterprise adoption.

TRADE-OFF I MADE. I rejected one expensive model for every incident and chose tiered routing. That added routing complexity and eval maintenance, but protected quality while making the unit economics viable.

Failure / learning. The early eval set was still growing while prompts were judged. I would freeze and version the first baseline before the first experiment.

SAFE-SAY. “This was my independent build, not an employer production program: $25 to $0.40 per triaged incident, with quality held on my graded eval set and every proposal cited.”
If asked for source: “Those are my build records as captured in Apple workbook I1, pages 41–42.”

Q1 — How did cost fall without quality falling? Most incidents were easy classes. I proved small models held on those classes against the eval set, then reserved the expensive path for the hard tail.

Q2 — What would break at FBA scale? Access review, data boundaries, eval-set maintenance and drift become programs of their own. I would keep a human approval gate until production evidence beats the human baseline.

20-second version. “I built an independent incident-triage agent with the eval set first and one rule: no citation, no proposal. Routing easy cases to small models moved cost from $25 to $0.40 per incident, a 98% reduction, while eval quality held. I would freeze the first eval version earlier.”

Question → Apple story router (16 LPs, compact)

LP	Real AIQB prompt	Apple chapter	Open / number
Customer Obsession	“Anticipate a customer need…” (AIQB: Customer Obsession Q3)	F4	Feature request became measured distributions; 200 lanes.
Ownership	“Something significant outside your area…” (AIQB: Ownership Q1)	I1 / D1	Independent build; or first WMS migration.
Invent and Simplify	“Complex problem… simple solution” (AIQB: Invent and Simplify Q1)	I1 / A3	No citation, no proposal; four systems to one pipeline.
Are Right, A Lot	“Made an error in judgment…” (AIQB: Are Right, A Lot Q5)	G1	Scenarios passed; concurrency was absent.
Learn and Be Curious	“Work outside your comfort area…” (AIQB: Learn and Be Curious Q2)	D1	Never ran WMS migration; delivered in eight months.
Hire and Develop	“Provided coaching…” (AIQB: Hire and Develop the Best Q4)	D3	QA authored the gate; do not claim direct-report coaching.
Highest Standards	“Decision between standards and delivery…” (AIQB: Insist on the Highest Standards Q4)	C3	94% vs 98%; throttled 30% to carts.
Think Big	“Opportunity… bigger than initial focus” (AIQB: Think Big Q1)	F4	Feature request became inventory program.
Bias for Action	“Calculated risk where speed was critical” (AIQB: Bias for Action Q1)	B3 / M1	One ruler under compression; or 4 AM triage.
Frugality	“Save costs or eliminate waste” (AIQB: Frugality Q1)	I1	$25 → $0.40 per incident.
Earn Trust	“Not able to meet a commitment” (AIQB: Earn Trust Q4)	G1 / G2	Lost sign-off; or training slipped 1.5 weeks.
Dive Deep	“Dig deep to get to root cause” (AIQB: Dive Deep Q2)	G1 / F2	Concurrent load; or measurement before carriers.
Backbone	“Strongly disagreed with manager…” (AIQB: Have Backbone Q1)	B2	Private check; two-day pressure test; sequence flipped.
Deliver Results	“Important project under tight deadline” (AIQB: Deliver Results Q1)	B3	Compressed program inside four weeks; other date held.
Earth’s Best Employer	“Change… improving coworkers’ work experience” (AIQB: Earth’s Best Employer Q3)	D3	Team authored ceremonies; no mandate.
Success & Scale	Use broad-consequence probe from the LP indicators.	A4 / A5	Retire parallel truth; ship a measured, owned gap.

3 · Apple-only story A02 — G1: the UAT that crashed

Assigned: Rocky — strongest real infrastructure failure and Bar Raiser answer. **Company:** Elementum. **LPs:** Are Right, A Lot · Earn Trust · Insist on the Highest Standards · Ownership.

LP proof. Are Right: names his wrong reflex and decision. Earn Trust: took the criteria miss to the sponsor as his. Standards: rebuilt UAT around numeric load criteria. Ownership: treats an implicit performance requirement as his gap, not the customer's fault.

60-second pitch. "Two days before UAT sign-off, five key users had passed all ten end-to-end scenarios on an Elementum track-and-trace app. Then the sponsor opened access more broadly and concurrent logins crashed the system. My first move made it worse: I reran my scenarios, they passed, and I sent screenshots. I was defending my test plan instead of reproducing the customer's shape. I owned the miss to the sponsor, simulated concurrency with engineering, and the team fixed it, but the sign-off date passed and confidence had to be rebuilt. I permanently changed the UAT contract: every critical scenario gets numeric entrance and exit criteria for uptime, page load and concurrent load at the customer's user count, volume and network. The later proof that the lesson stuck was a Flexport gate of 500 containers in 20 minutes at 99.6% connectivity before customer testing."

S On an Elementum track-and-trace application, UAT sign-off was two days away. Five key users had completed ten end-to-end scenarios each, and my test evidence was green. record

T I owned readiness. I needed to earn customer sign-off and protect launch confidence, including requirements the written scenario list had not made explicit.

A When the sponsor said users could not complete a flow, I first reran the same scenarios and sent screenshots showing they passed. That was my central failure: I tried to prove innocence. I then reproduced the customer's operating shape and found concurrent logins crashed a system my criteria had never load-tested. I told the sponsor the gap was mine—the customer had exposed an implicit performance requirement I failed to surface. Engineering simulated the concurrent load and worked the fix while I rewrote the UAT contract: numeric uptime, page-load and concurrent-load criteria at the customer's user count, data volume and network, with entrance and exit bars written before testing.

R The sign-off date was missed and trust had to be rebuilt. record The structural correction persisted: a later Flexport launch gate required 500 containers in 20 minutes at 99.6% connectivity before customer testing. record-from-docs I no longer accept "works for us" as readiness evidence.

TRADE-OFF I MADE. After finding the cause, I chose round-the-clock engineering effort and a transparent missed sign-off over relaxing the performance requirement. That spent schedule margin and team capacity, but did not ask the customer to accept an unproven system.

Failure / learning. The actual failure was defensive diagnosis: I mistook my coverage for the truth. The first hour of an escalation now goes to reproducing the customer's shape, not proving our innocence.

SAFE-SAY. "Five key users passed ten scenarios, but concurrent access crashed the system two days before sign-off; my criteria omitted load, and the deadline was missed."
If asked for source: "The failure details are Apple workbook G1, pages 43–44; the later performance proof is in the Flexport TPM status source."

Q1 — Wasn't the sponsor at fault for opening access broadly? No. Users exercised the system the way their work demanded. Their behavior exposed an implicit requirement my readiness criteria should have surfaced.

Q2 — Why did you send screenshots? Because the scenarios genuinely passed for me, and I confused test coverage with customer truth. That defensive reflex is the behavior I would take back.

20-second version. "Five users passed ten UAT scenarios, but broader concurrent access crashed the system two days before sign-off. I first defended with screenshots—my mistake—then owned that load was absent from my criteria. The date was missed; every gate I run now tests at the customer's concurrency and volume."

3 · Apple-only story A03 — B3: two programs, one ruler

Assigned: James — sequencing, shared engineering capacity, process governance and floor adoption. **Company:** Flexport. **LPs:** Bias for Action · Deliver Results · Earn Trust · Have Backbone; Disagree and Commit.

LP proof. Bias: made capacity decisions inside a four-week compression. Deliver: compressed program landed and the original date held. Trust: made the collision visible instead of hiding load. Backbone: challenged the resource pull with priced consequences, then committed.

60-second pitch. “Leadership pulled a strategic go-live forward one month and moved engineers off my program to support it. Rather than let two programs run separate escalation systems, I made them one operating problem: one RAID log, one 45-minute daily ruling forum, and one issue grammar—blocker, non-blocker, or requirements gap. True blockers moved through onsite and offshore passes with a written handoff, so issues moved around the clock without asking people to. I escalated only priced decisions: option A costs this; option B costs that. Both programs landed—the compressed one inside four weeks, mine on its original date. About $200K per month per DC was the program-doc value rate. The honest cost was the team’s calendar, and my miss was shipping the ten-step floor guide only a week before cutover. Now operator documentation is an entrance criterion, not a final-week task.”

S At Flexport, leadership advanced a strategic go-live by a month and shared my engineers across that work and my existing launch. Two programs had one team, an immovable date, and about $200K per month per DC at stake in the program record. record

T I had to make the resource collision explicit, protect floor adoption, and land the accelerated program without moving my original date.

A I did not fight the priority after the value was visible; I challenged how it would be executed. I put both programs in one RAID log and one hard 45-minute daily forum. I imposed one grammar—true blocker, non-blocker, or requirements gap—so teams could not win attention by labeling everything urgent. Most alleged blockers were reclassified within a week. True blockers entered a two-pass war room: onsite worked the first pass, offshore continued from a written handoff, and nobody was asked to work continuously. Go/no-go read the true-blocker burn-down to an agreed floor. Escalations went upward the same day as priced choices, not complaints. I also produced a ten-step quick-reference guide for floor adoption.

R The accelerated program landed inside four weeks and my program held its original date. record The defendable economic statement is the program-doc rate—about $200K per month per DC—not a larger cumulative claim. The operating mechanism made shared capacity visible and gave one forum authority over both programs.

TRADE-OFF I MADE. I accepted bounded compression on the team’s calendar and rejected two independent priority systems. The written handoff and time-boxed forum cost coordination effort but prevented an unmanaged slip and continuous heroics.

Failure / learning. The operator guide shipped only one week before cutover, after floor questions had already arrived. Under compression, documentation must be an entrance criterion.

SAFE-SAY. “About $200K per month per DC was at stake—the rate in the program record; the compressed program landed inside four weeks and my original date held.”
If asked for source: “That rate and the operating mechanism are recorded in Apple workbook B3, pages 19–21; I do not inflate the monthly rate into a banked annual claim.”

Q1 — Did you oppose leadership taking your engineers? I made the collision and cost visible, but once the pull-forward was priced it was probably the right business decision. I committed and designed one governance system for both.

Q2 — What actually slipped? No public date slipped. The cost was the team’s calendar and a late operator guide. Naming that cost matters; a “free” compression merely hides where the cost landed.

20-second version. “When two launches shared one team, I ran one RAID log, one 45-minute forum and one blocker grammar. True blockers followed written onsite-to-offshore handoffs. The compressed launch landed inside four weeks, mine held its date, and I learned to make the operator guide an entrance criterion.”

Part 6 in full · G2 — the RF-device script

Best interviewer: Rocky backup; James if asked about training/change control. **Company:** Sephora. **LPs:** Are Right, A Lot · Earn Trust · Deliver Results.

Opener. “I missed a training gate because I scored a dependency by effort instead of impact. The script was a small task; its position on the critical path was not.”

S During Sephora’s RP-to-JDA upgrade, training sign-off depended on hundreds of RF guns, printers and workstations being converted. The device team estimated three to four days, so I treated it as low effort and gave it low attention. record

T I owned the readiness chain for an eight-month, dual-DC migration. I had to prove device readiness before training without moving the final go-live.

A I scheduled a device test days before training. The conversion script failed because refreshed RF hardware did not run the old code. My first-principles read was not “the script is buggy”; it was that my risk model was wrong. A small task in front of a go-live exit criterion was a high-impact dependency and had no what-if plan. With key resources on COVID night shifts, the manual fallback could not finish inside the training window. I told leadership the 1.5-week training slip was mine. I then added a what-if and mitigation to every cross-functional dependency regardless of effort and moved proven device readiness into training’s entrance criteria.

R Training slipped 1.5 weeks, but the go-live date held; the broader migration landed on time and about 3% under its roughly $1.8M budget. record The later mock-cutover discipline—7% to 1.8% to 0.3% against a 0.5% line—shows the what-if habit institutionalized.

TRADE-OFF I MADE. I accepted a visible training slip rather than declare unproven devices ready. That consumed scarce SME windows but protected the live date.

Failure / learning. Catching it with my own test saved the go-live; it did not erase the planning failure. Impact, not effort, now decides risk attention.

SAFE-SAY. “Hundreds of devices; a three-to-four-day estimate; device test before training; training moved 1.5 weeks; go-live held.”
If asked for source: “Apple workbook G2, pages 44–45, reconciles two earlier device-count tellings and explicitly tells me to say ‘hundreds.’”

Q1 — Why is the miss yours if the device team estimated it? I accepted an effort estimate as a risk assessment. The impact and lack of fallback were my planning responsibility.

Q2 — Is a 1.5-week training move a big enough failure? G1 is the larger customer-facing miss. G2 matters because small unplanned dependencies are how mature programs fail.

20-second version. “A three-to-four-day device script failed before training because refreshed RF hardware was incompatible. I had scored risk by effort, not critical-path impact. Training slipped 1.5 weeks, go-live held, and proven device readiness is now an entrance criterion.”

Part 6 in full · G3 — the security review I discovered

Best interviewer: Rocky infrastructure; Venkata behavioral backup. **Company:** Flexport. **LPs:** Are Right, A Lot · Earn Trust · Dive Deep · Ownership.

Opener. “I planned the extracts, loads, metrics and parallel run, but I discovered the access review mid-build instead of planning it. A small two-week miss exposed a structural gap in how I scoped data programs.”

S At Flexport I was replacing a manual four-system weekly review with a Snowflake pipeline. The source included ticket data carrying customer content. I scoped the pipeline and correctness gate, but not the data-access security review. record

T I owned the BRD and cutover. I had to complete the access review without skipping the Monday operating review or weakening the one-percent parity gate.

A When the review surfaced mid-build, I owned the two-week miss upward as a scoping failure, not “slow security.” I had treated approval as a formality instead of a lead-time workstream. I re-sequenced rather than bypass it: the manual path stayed live during the parallel run, so the review continued every Monday. I documented the cross-reference table, named the data classes and made read access explicit. I then changed the kickoff checklist permanently: security has an owner and lead time in the BRD, and every data program starts by asking whose approval the data needs and how long it takes.

R The access review cost two weeks of schedule margin, but no weekly review was skipped. The pipeline cut over only after manual and automated metrics agreed within one percent for consecutive weeks, and system accuracy closed at 90% from a 60% baseline. record The miss cost margin, not delivery.

TRADE-OFF I MADE. I kept the labor-intensive manual path alive and rejected a premature cutover. That spent two more weeks of my time but preserved delivery and access integrity.

Failure / learning. The parallel run saved me partly by luck—it was designed for correctness, not schedule resilience. Now I deliberately keep the old path until the new path clears both access and correctness.

SAFE-SAY. “I under-planned the customer-data access review by two weeks; the manual path kept every Monday review alive, and cutover still waited for one-percent parity.”
If asked for source: “Apple workbook G3, pages 45–46, and A3; the two-week miss and parity gate are record, not modeled.”

Q1 — Why call a two-week slip a failure? Because the cause was structural. Every customer-data program needs approval; absent a checklist change, I would repeat the miss.

Q2 — Why not ask for an exception? Customer-content access was a gate. Bypassing it would convert a schedule miss into a trust and compliance risk.

20-second version. “I discovered a customer-data security review mid-build and lost two weeks because it was absent from my BRD. The manual path kept the weekly review alive; cutover still waited for one-percent parity. Security lead time is now planned at kickoff, never discovered.”

Part 0 in full · “How I run a program”

Say this in 35 seconds. “I use the same five-part system on every program. First, baseline the KPI before touching the process. Second, publish one scorecard on one cadence with a grain and date on every number. Third, write numeric entrance and exit criteria that can actually stop the program. Fourth, when a number goes red, trace it to the root before spending money on the symptom. Fifth, put the cause, owner and date into the same cadence, then use the same number to prove the fix went green.” Apple pp4–5.

Move	Entry	Delivered artifact	Exit / proof	Tomorrow’s translation
1 · Baseline	Business problem and decision owner named.	KPI definition, grain, date, owner, starting value.	Owner signs the starting number; no “before” invented later.	Rocky: deployment baseline. James: change-volume/error baseline. Venkata: customer and unit-economics baseline.
2 · One scorecard	Definitions reconciled; duplicate dashboards exposed.	WBR, burn-down or issues log with outputs over inputs.	The decision forum reads one instrument on the same day each week.	“Two dashboards is zero dashboards.”
3 · Numeric gates	Entrance evidence and exit threshold published before testing.	Go/no-go line, rollback trigger, fallback and authorized caller.	The gate has stopped or slowed work at least when evidence missed.	“A gate that cannot stop the program is decoration.”
4 · First-principles triage	A red metric, not a theory.	Defect class / causal trace; symptom separated from mechanism.	Root cause reproduced at the customer or operator’s shape.	G1 concurrency, C3 zone logic, M1 scheduler heartbeat.
5 · Correct in cadence	Cause accepted; owner empowered.	Red item with cause, owner, due date and verification method.	The same KPI that found the miss proves the correction.	No side status, no changed denominator, no victory by calendar.

Framework trade-off. This system willingly spends speed before a gate—calibration, parallel run, rehearsal—to buy faster and safer scaling after the gate. It rejects both a big-bang launch and endless analysis.

Framework failure line. “The three scars behind the system are G1: I omitted load, G2: I scored risk by effort, and G3: I discovered access approval. The framework is those misses turned into controls.”

4 · Apple resume → proof story map

Every experience bullet in the Apple-tailored resume is mapped. The aggregate summary claim is included as a guardrail, but it should not be volunteered because the underlying addition is not reconciled in the Amazon packet.

Resume bullet	Proof story	Number to land	Basis / safe line
S/4HANA ↔ ISM reverse/forward inventory; one “available”; MCS retired; zero incidents.	S1 + Apple E1; S4 for the rule failure.	Zero customer-facing incidents.	record “I owned policy and integration governance; ERP engineers owned configuration.”
Portfolio execution system: RAID, 836-item log, 343-task runbook, rollback, 60+ stakeholders.	S2/C2 for 836; S1/S2 cutover family.	836 rows; 343 tasks / ~815 task-hours; 60+ stakeholders.	record Call it the umbrella program’s log, not an ISM-only log.
UDC omni NPI on BlueYonder + robotics; staged gates; +15% efficiency.	S2; Apple C1/C3.	+15% processing efficiency; zero customer incidents.	record DC Ops’ measurement.
Re-sequenced 18-month roadmap; 66% effort reduction; about $5M avoided in six months.	S12; Apple B1/B2.	18 months → value in 6; 66%; about $5M avoided.	record State the avoided-cost noun once.
Scaled 4PL visibility 7 → 68; CTS; Snowflake accuracy.	S11 and S16; Apple A1–A3.	7 → 68 (9.7×); $0.66 → $0.03; system accuracy 60% → 90%.	record Keep S11 and S16 as separate stories.
Dual-DC legacy ERP → JDA in eight months; three mocks; $20M pipeline.	S18; Apple D1/D2/G2.	7% → 1.8% → 0.3% vs 0.5%; eight months; $20M pipeline of four programs.	record Pipeline value, not banked savings.
VP-sponsored 20-person org conversion; four-week cadence; defects down.	S15; Apple D3.	Six-week → four-week cadence in six weeks; critical defects −50%.	record No direct-report claim; QA authored the gate.
SAP supply/demand view; daily MD04/MB52; forecast accuracy; safety stock.	S6; Apple F3.	70% → 85%; about $2M safety stock released.	record Planner collaboration increased 50%; do not call it effort reduction.
1,000 supplier/carrier routes; ≥95% valid ASN; completeness.	S9; Apple F1.	A thousand-lane program across 25 European locations; completeness 60% → 95%.	record If discussing phasing: 597 first is a user anchor, not the settled delivered count.
MetricStream dual-hat PM/solution lead: SOWs, estimates, budgets, onshore/offshore UAT/cutover/hypercare.	Resume-only role proof; B3 written handoff is a transferable operating example.	No safe project-outcome number in the source set.	record “I owned SOWs and delivery; I will not invent a client or value.”
Manhattan OMS across 3 DCs/100 stores; stockouts, fill and protected sales.	S13; Apple M1.	3 DCs + 100 stores; 99% fill vs 95%; stockouts −20%; about $8M of the day’s sales protected.	record Say about $6M was on the line when paged; keep “protected” as the $8M meaning.
Summary: “$27M+ cost savings.”	Aggregate across multiple programs; no reconciled ledger in packet.	Do not land this aggregate.	Safe: “I’ll use the program-level figures individually rather than add unlike savings, avoidance and protected revenue.”

90-second resume walk — Rocky: infrastructure / program lens

S “My career has been at the seam between operational rules and the infrastructure that must carry them.”

T “The recurring job has been to move a live operation without losing the customer promise.”

A “At Sephora I currently lead inventory-integration programs across S/4HANA, WMS, OMS and warehouse automation. My operating system is one scorecard, entrance and exit gates, rehearsed cutover and numeric rollback. On the dual-DC WMS move, I had never run that migration, so I used gates instead of experience: three mocks moved reconciliation from 7% to 1.8% to 0.3% against a 0.5% line published before mock one. At Flexport I ran a global visibility rollout and specified a Snowflake pipeline that replaced a four-system manual review; the infrastructure team built it and I owned the metrics and one-percent parallel-run gate. Earlier, at Elementum and Manhattan, I learned the same lesson on customer systems: test at the customer’s shape and instrument silence as a failure.”

R “That is the infrastructure program leader I bring: I do not claim to build the pipe; I make deployment evidence, ownership and rollback unambiguous.”

90-second resume walk — James: supply-chain process lens

S “I have spent fifteen years converting supply-chain policy into a process operators can run.”

T “The throughline is one governed decision path across systems, sites and teams.”

A “At Sephora, that meant one signed definition of available stock and a live Utah facility moving from two systemic warehouses to one omni pool. I pre-wired an architecture council with one row per impacted system, then staged purchasing and inbound before the inventory flip. The program used an 836-row work-triage log and a 343-task cutover runbook; zero customer-facing incidents and DC Ops measured processing efficiency up 15%. At Flexport, I re-sequenced an 18-month roadmap using cost-to-serve and later handled two launches competing for one engineering team with one RAID log, one 45-minute daily forum and one blocker grammar. At Elementum, I phased a thousand-lane program by value and gated each cohort on data quality.”

R “My process-improvement result is not a slide: it is a rule, a self-service path with validation, and a post-change number the business owns.”

90-second resume walk — Venkata: product lens

S “I am a supply-chain program leader who treats operating mechanisms as products.”

T “I define the customer problem, the metric and the graduation gate, then sequence engineering around evidence.”

A “At Flexport, I took Shipment Visibility from seven pilots to 68 customers behind calibration and six graduation criteria; the 68-customer and 170-user targets landed two months early while cost-to-serve moved from $0.66 to $0.03 per container. On the forwarding app, I changed the roadmap from operator-first to partner-first because that sequence moved about twice the cost-to-serve reduction; value arrived in six months instead of eighteen with 66% less effort. At Sephora, I made the inventory policy business-readable before configuration and let QA author the gate on a 20-person cadence change. Independently, I built an incident-triage agent with the eval set first, citations on every proposal and unit cost from $25 to $0.40.”

R “My product test is simple: does a customer or operator make a better decision, can we prove it, and can the system scale without adding people linearly?”

5 · Numbers check — Apple v11 versus CANON v2

This table includes every Apple-involved conflict or wording drift called out by NUMBERS-RECON, plus the resume aggregate. Precedence: primary source document → Apple v11 → Amazon master. When evidence remains inconsistent, the say-aloud value is the conservative intersection.

Story / metric	Apple v11	Other canon / conflict	Safe aloud
A1/S11 customer scale	7 → 68 customers; 170 MAU landed; 32,000 shipments public target.	WBR source contains incompatible promotional multipliers; master once implied all public targets landed.	“7 to 68 customers—9.7 times—and 170 users landed two months early. 32,000 shipments was a target.”
A1/A2 CTS start	About $1.00 in hand-carried pilot weeks, then $0.66, then $0.03.	Canon uses the stable manual baseline, not the hand-carried setup phase.	“$0.66 to $0.03 per container, about 95%.” Mention “about a dollar in hand-carried weeks” only if asked.
A1 first customer	Shadow accounts include Marc Fisher / Michelin.	Pilot schedule names Ta Chen / FAM Brands as wave one; status doc names Marc Fisher onboarding.	“The first two hand-carried customers.” No names.
A2 manual effort	About four hours a week at worst.	BRD says 1.5–2 hours per snapshot and separately prices 30 hours/week across people and two WBRs.	For S11: “about four hours a week at worst.” For S16 BRD pricing, state the 30 → 6 hours/week assumptions separately.
A2 dry run	100% processed, 86% tracked, job stories 98.4%.	Master rounded tracked performance differently.	“100% processed; 86% tracked; job stories 98.4%.”
A3/S16 priced baseline	More than $100K from PM time plus decision risk.	BRD arithmetic is $103,680 from 30 → 6 hours/week at assumed $90/hour; master’s hours/risk split is modeled.	“The BRD priced the baseline at $103,680 a year on its assumptions—priced, not claimed as saving.”
B1 launch identity/date	Calls April 2022 the MVP with 11 partners / 10 countries; same chapter’s box puts export MVP in Q1 2023.	Solution doc supports the later export launch.	“The import-side app went live April 2022 with 11 partners in 10 countries; export scope followed later.”
B2 value label	Uses both annual reduction plus overhead and avoided cost.	Resume and canon support avoided cost; overhead has no primary support.	“About $5M of avoided cost,” once. Drop the overhead claim.
C1/C2 duration	C1 says 15 months; C2 says 14 months.	Dated program window depends on whether hypercare is included.	“About 15 months, discovery through hypercare exit.”
C1/C2 tracks	C1 says 15+ tracks; C2 says about 30 build tracks.	Different grains are not clearly labeled.	“About 30 build tracks” for the build plan; avoid the smaller track count.
C1/C4 systems	About a dozen impacted systems.	New council deck supports seven families / about a dozen domains / about two dozen named systems.	“About a dozen system domains; the council impact table named about two dozen systems.”
D1 budget / value	About $1.8M, 3% under; $20M pipeline of four programs.	An older loop packet carried incompatible budget and time-value wording.	Use Apple: “About $1.8M, roughly 3% under; a $20M pipeline of four programs was unblocked.”
G2 devices	Two source tellings differ on device count and estimate.	Canon explicitly resolves to nonnumeric fleet wording and the longer estimate.	“Hundreds of devices; three-to-four-day estimate; training moved 1.5 weeks; go-live held.”
F1/S9 delivered lanes	A thousand lanes onboarded across 25 European locations.	Master says a thousand asked, 597 first for 80% of spend, another wave, remainder deferred.	“A thousand-lane program across 25 European locations; I phased by value. The 597 first-wave figure is my earlier user anchor.”
F2/S10 timing	99% inside a two-month bar.	Master says about three months.	“99% within a quarter.”

F3/S6 planner metric	Planner collaboration up 50%.	Master previously described planner effort down 50%.	“Planner collaboration increased 50%.”
F4/S8 value noun	About $1.5M of carrying cost released.	Master described one-time inventory release and modeled carrying rates inconsistently.	“About $1.5M of inventory carrying cost released; I do not annualize it.”
M1/S13 $8M meaning	Uses $8M as both at risk and protected; also says about $6M on the line at page time.	Resume says about $8M protected.	“About $6M was on the line when the page fired; about $8M of the day’s sales was protected.”
Resume aggregate	$27M+ cost savings.	No reconciled addition; underlying figures mix savings, avoidance, released inventory and protected sales.	Do not use the aggregate. State program figures individually.

6 · What is usable from earlier packets tomorrow

Earlier packet / story	Interviewer	Why it is usable	Integrity condition
Walmart war book — governed delivery-promise buffer / pre-purchase WBR / seller settings.	James, only if he gives a placement/configuration case.	Strong architecture vocabulary: one governed dial, validation before change, post-change WBR, escape routing and capacity signals.	**DESIGN CASE.** Say "I designed" and "in the model." Pair with lived F4 in one sentence. Do not claim Walmart delivery results.
Walmart war book — promise decomposition and Andon.	Venkata, if asked how to define product metrics.	Separates inputs from customer outputs and makes a response mechanism part of the product.	Illustrative case inputs only; no delivered dollar or engagement claim.
Scaia manager packet — honest capability boundaries.	James.	Useful language: BlueYonder/JDA execution experience is deep; no claim of hands-on BlueYonder planning-suite configuration. "I have not run a factory" is an honest boundary.	Use the boundary language, not that packet's older SV automation or inventory nouns; those drift from current canon.
Scaia manager packet — newest-to-oldest career throughline.	All three.	Good structure: Sephora policy/cutover → Flexport visibility/product → Elementum planning/transport → Manhattan peak.	Use the three reconciled 90-second versions in this add-on, not the older packet's numbers.
Scaia manager packet — MetricStream delivery bridge.	Rocky.	Proves SOW, estimates, onshore/offshore delivery, UAT, cutover and hypercare when asked about vendor governance.	No client, team-size, dollar or outcome is in the source set; keep it qualitative.
Adobe packet — named technical + functional owner on every boundary.	Rocky and James.	Directly useful for infrastructure interfaces and James's centralized policy-platform migration.	Phrase as the governance Rajesh would install; do not imply ownership of Adobe's ECC conversion.
Adobe packet — "I do not run a methodology religion."	Rocky.	Clear trade: iterative design/build; phase-gated cutover where the date and task list are fixed.	Prove with D3 four-week cadence and D1/D2 rehearsed cutover.
Adobe packet — separate business rule from requirement.	James.	Placement-policy fit: business signs the rule; systems implement plants, interfaces and contracts that make it true.	Use S1/E1 as a one-line bridge only; it was already told today.
Adobe packet — adoption means the old path closes.	Venkata.	Product depth: training and usage are weak evidence if the old process remains available.	Use MCS retirement or the A3 pipeline cutover as proof; no new number.

7 · VERIFY / resolve before saying an exact disputed fact

V1 · S9 delivered count. Apple/resume and master differ on what went live. **Safe:** “It was a thousand-lane program across 25 European locations; I phased by value, with 597 high-value lanes first in my earlier record.”

V2 · S10 exact duration. Apple and master differ. **Safe:** “Data quality reached 99% within a quarter.”

V3 · B1 April launch identity. Apple’s prose and its own math box differ. **Safe:** “The import-side app went live in April 2022 with 11 partners in 10 countries; the export scope followed later.”

V4 · A1 first-customer names. Apple and pilot documents name different populations. **Safe:** “The first two hand-carried customers.”

V5 · G2 device count. Source tellings differ. **Safe:** “Hundreds of RF devices.”

V6 · MetricStream outcomes. Resume supports responsibilities, not client results. **Safe:** “I owned SOWs, estimates, budgets and onshore/offshore delivery through UAT, cutover and hypercare; I will not attach a client or dollar that is not in my records.”

V7 · Resume aggregate. The addition is not reconciled. **Safe:** “I will use each program’s number with its noun rather than blend savings, avoided cost and protected revenue.”

Source trace — every quantitative claim in §§3–4

Number	Story / resume proof	Source file	Page / row	Match

About $6M on line; about $8M sales protected	S13/M1 resume bullet	Apple v11 M1; Apple-tailored resume	pp40–41; resume p1	CONFLICT resolved by noun

Final say-aloud guardrails

- Every answer is first person about Rajesh’s mechanism and decision; team-built code and operations work stay credited to the team.
- Walmart material is case design, not delivered client work.
- The Apple-only agent is an independent build, not a production employer deployment.
- Protected revenue, avoided cost, released inventory and priced baselines are different nouns and are never added.
- The UDC 836-row log is the umbrella/UDC program artifact, not an ISM-only artifact.
- Finished-goods planning grain only when discussing manufacturing or inventory planning.

> **Close.** “The common thread is not a tool. I baseline the number, put one instrument in the room, publish a gate that can stop me, and own the miss when the evidence says I was wrong.”

Sources used: Apple workbook v11 (49 pp); Apple-tailored resume; Amazon L6 SCM master; NUMBERS-RECON CANON v2; current panel files; Walmart war book; Scaia manager packet; Adobe 30-minute packet; primary sources named in the trace. No new client, headcount, value or outcome was inferred.

Part 3 — Rocky Goforth — Infrastructure Program Management

10:00 AM · Senior Manager, Amazon Infrastructure · Bar Raiser

Rajesh Rishiyur Chandrasekaran · SDLC, deployment, consensus, cutover, hypercare

1. Cram sheet
2–3. How I run a program
4. Building consensus
5. Ambiguity
6. Stakeholders & communication
7. Cost versus speed
8. Programs at a glance
9–10. Question router
11. Ask Rocky · verify

CRAM SHEET — read this immediately before 10:00

Profile hooks. Rocky is an infrastructure/engineering leader and the Bar Raiser. Speak in release trains, architecture decisions, dependency ownership, numeric gates, rollback, incident posture, and mechanisms that survive the launch. Separate my program ownership from engineering's code ownership. No supply-chain analysis unless it explains a deployment decision.

ORDER I PLAY THE STORIES

#	POINTER	WHY IT FITS	NUMBER TO LAND
1	**UDC pack B1**	Dual inventory end to end: discovery → council → build/test → two cutovers → hypercare.	**44 requirement rows / 23 systems** (record-from-docs); zero customer-facing incidents (record).
2	**UDC pack B2**	Canada discovery, phased rollout, bounded scope; outcome is VERIFY.	**99 brands in 20 / 40 / 39 waves** (plan, record-from-docs).
3	**P2**	RP→JDA migration: rehearsals and evidence-based go/no-go.	**7.0% → 1.8% → 0.3%** against a 0.5% tolerance (record).
4	**P3**	Locus: throttle a robotics deployment when quality misses the bar.	**98% gate; week two 94%; full volume week three** (record / user anchor).
5	**P4**	Crux: decommission as a migration program, not a dashboard debate.	**79 customers / 294,581 annual containers** (record-from-docs).
6	**Failure: UDC B5**, then **G2**	I missed the FSD date; or my RF-device script broke the training gate.	Planned Jul 26, signed Aug 14 (record); training +1.5 weeks, go-live held (record).
7	**BR bank R1–R9**	Use for LP depth; do not force another UDC retelling.	Choose the number shown in the router.

FIVE NUMBERS NEVER TO GET WRONG

1. **UDC:** about 15 months, discovery through hypercare; 44 requirements across 23 named systems; about 30 build tracks are a user anchor.
2. **JDA:** two DCs, eight months, about $1.8M budget and roughly 3% under (record).
3. **Locus:** 98% gate; 94% in week two; full volume in week three (record / user anchor).
4. **Canada:** about 13% of volume; 99 planned brands in 20 / 40 / 39 waves; about 2.5M units front-loaded. These are discovery-plan facts, not outcomes.
5. **RF failure:** hundreds of devices; device testing came before training; training moved 1.5 weeks; go-live held.

THREE OPENING SENTENCES

"I run programs as an evidence chain: discovery earns design, design earns build, testing earns cutover, and measured stability earns close."

"My role is to make the decision system and the release safe; engineering owns the code, and I own the cross-system contract, gates, escalation, and go/no-go recommendation."

"I will give you the trade-off, the stop line, and what I changed after the miss in every answer."

HOW I RUN A PROGRAM

60-SECOND SPOKEN ANSWER

"I run five gated phases: Discover, Design, Build and Test, Cutover, then Hypercare and Close. Each phase has an entry bar, an artifact I personally deliver, a graduating bar that says the work is mature enough to review, and an exit bar that can stop the program. I use one requirement table, one RAID log, one decision log, and one counted issues log from discovery through production. Weekly steering has an IT block for architecture, interfaces, quality and release risk, then a business block for process readiness, training and adoption; the join is a decision, never two status reports. Before cutover, every critical path is rehearsed, every rollback trigger is numeric, and go/no-go reads counted rows. Hypercare ends on blockers per day and control ownership, not because the calendar says the launch is old."

PHASE	ENTRY BAR	WHAT I DELIVER	GRADUATING BAR	EXIT BAR
1 · Discover	Named sponsor; problem and customer impact stated; current landscape available or explicitly unknown.	I map stakeholders and system boundaries; write the problem, baseline, assumptions, constraints, out-of-scope fence, and first RAID; turn interviews into owned requirement rows.	Every material flow can be said back end to end; assumptions have owners and expiry dates; options are testable.	Scope, success measures, system owners, and open questions are signed. I do not design against an unnamed dependency.
2 · Design / architecture council	Discovery pack complete; requirements have owners; options include cost, speed, risk and reversibility.	I pre-wire each row with its owner; run working sessions to one table; write architecture, interfaces, nonfunctional bars, transition states, test skeleton, decision log, and the explicit decision ask.	LOE exists for each impacted team; objections are converted into requirement or risk rows; rejected options remain visible.	Council decides architecture, sequence and scope fence; FSD is signed; no open "who owns this?" row. A review without a decision is not an exit.
3 · Build & Test	Signed design; environments, test data and access planned; stories trace to requirements; peak freeze on calendar.	I run the integrated plan, RAID and decision logs; require a matrix-cell reference for definition of done; sequence SIT → E2E → UAT; publish severity and stop lines before results.	Contract defects are closed; full flows pass in dated E2E events; business has seen the control screens during build; mocks are trending to tolerance.	Blocker + Critical open = 0; performance, data and operational readiness bars pass; training/device dependencies pass in the right order.

TRADE-OFF I MAKE: I spend time early on ownership and measurable gates, rejecting faster "start coding and reconcile later." I recover the time by preventing council rework, parallel interpretations, and date-driven go/no-go.

Failure / learning: UDC's late FSD and the RF-device miss taught me that a gate is only real when its predecessor evidence and decision owner are on the integrated plan.

SAFE-SAY: "A gate that cannot stop the program is decoration; I publish the stop line before the first test."
Ownership sentence: "I wrote the program artifacts and made the recommendation; architects and engineers designed and built their components."

CUTOVER, HYPERCARE, AND THE CADENCE THAT CONNECTS THEM

PHASE	ENTRY BAR	WHAT I DELIVER	GRADUATING BAR	EXIT BAR
4 · Cutover	Exit memo from Build & Test; freeze active; approved runbook; staffed bridge; backups and switches verified.	I create owner / duration / predecessor rows, control-screen roles, reconciliation checkpoints, business communications, go/no-go read, rollback triggers, and a decision clock. The rejected big-bang option stays in the pack.	Mocks meet tolerance; all named owners acknowledge; data snapshots and rollback paths are proven; the business understands service impact.	Steering reads counted rows and says go or hold. Post-switch invariants pass, no duplicate truth is published, and rollback triggers remain clear until stability is proven.
5 · Hypercare / Close	Production live; known issues transferred with severity and owner; monitoring and daily reconciliation running.	I run daily blocker burn-down, incident and customer-impact review, defect aging, reconciliation, decision log, and an as-built / control-owner handoff.	Blockers per day stay below the agreed line; no new critical pattern; recurring work is owned by an operating team; release notes match what shipped.	Exit memo is signed from measured stability, not elapsed days; residual work enters the normal release train; retrospective changes the next template.

Weekly steering: one meeting, two blocks

IT block: architecture decisions, interfaces, environment/access, quality trend, critical path, release and rollback risk.

Business block: process readiness, control owners, training, cutover communications, adoption and customer impact.

Join: metric → trend → driver → decision needed. I escalate only a decision, with a recommendation and expiry date.

Four logs, four jobs

Requirements: what must be true, owner, acceptance evidence.

RAID: threat or dependency, trigger, mitigation, owner, date.

Decision: options, decider, date, rationale, consequences.

Issues: observed defect, severity, owner, aging, closure evidence. Status never substitutes for one of these.

Go / hold / rollback — the spoken read

S The calendar says launch; evidence may disagree.

T I must make the safest reversible recommendation without hiding business cost.

A I read the rows in order: open Blocker/Critical count; failed E2E cells; mock variance against the pre-published tolerance; environment and control-owner readiness; then named rollback triggers. I state the cost of hold and the blast radius of go. If a trigger is crossed, I hold or roll back without renegotiating the line in the room.

R On RP→JDA, mock variance moved from 7.0% to 1.8% to 0.3% against a 0.5% tolerance (record), so the release earned go.

Proof story + number: UDC B1 — a roughly 15-month program (record), two staged go-lives, zero customer-facing incidents (record), and hypercare burn-down read from counted rows rather than confidence.

TRADE-OFF I MADE: I rejected one dramatic launch in favor of staged truth changes. It added an interim operating state, but reduced rollback scope and protected peak.

What I changed: after the RF-device script failure, I made device validation an explicit predecessor to training, not a parallel “readiness” line.

FRAMEWORK CARD 1 · SPOKEN-READY

BUILDING CONSENSUS — MAKE THE COUNCIL A DECISION, NOT A REVIEW

LPs: Earn Trust · Have Backbone; Disagree and Commit · Ownership · Insist on the Highest Standards.

SPOKEN FRAMEWORK

"Consensus is not everyone liking the answer. It is every material objection represented accurately, a named decider choosing with the consequences visible, and the owners committing to execute. Before a council, I pre-wire every requirement row with its owner. Working sessions converge on one table, not competing decks. I convert objections into spec, option, risk, or out-of-scope rows. The council receives the unresolved decisions and my recommendation; it does not discover the program live. After the decision, I record who disagreed, what evidence would reopen it, and what commitment now means."

S — Situation. UDC was one physical building moving from two systemic warehouses to one omni facility while upgrading the WMS, with seven system families and about two dozen named systems on the impact view (record-from-docs).

T — Task. I had to get architecture, engineering, finance, digital, operations and planning to accept one transition design without turning sign-off into serial vetoes.

A — Action. I put 44 requirements in one owner-tagged table across 23 named systems; pre-wired each row; ran disagreements in working sessions; turned "this will break my flow" into an interface, acceptance, or risk row; kept current state, target state, interim state and rejected options visible; then asked council for three decisions: architecture, staged sequence, and scope / freeze boundary. Once decided, owners either committed or documented the evidence that could reopen the row.

R — Result. The sign-off pack created one buildable contract. The planned late-July FSD landed August 14, so I do not claim the gate held to plan; the correction was to expose predecessor evidence earlier.

Disagree-and-commit mechanics

1. **Restate:** I write the strongest version of the objection and get the owner to confirm it.
2. **Classify:** requirement, risk, option, assumption, or preference. Preference does not silently become a blocker.
3. **Price:** impact on customer, schedule, cost, reversibility, and the owner's operating burden.
4. **Decide:** named decider, date, rationale, rejected option, and evidence that can reopen it.
5. **Commit:** dissent remains in the log; execution follows the chosen row. I follow up privately if the owner cannot commit.

TRADE-OFF I MADE: I accepted upstream build at risk from June 9 before July 31 council sign-off, but fenced it to reversible merchandising work. WMS conversion, outbound, finance, and EDW waited for the decision.

Proof story + number: UDC council — **44 requirement rows / 23 named systems** with owner-tagged sign-off (record-from-docs).

SAFE-SAY: "The primary deck records 44 requirements and 23 named systems; I use 'about a dozen domains' only as a spoken simplification."
If asked who built it: "I owned the council mechanism and integrated specification; system architects owned their designs and engineers owned implementation."

Failure / learning: Pre-wiring agreement is not enough; I now pre-wire the evidence required to graduate each row, because UDC's FSD date still slipped.

FRAMEWORK CARD 2 · SPOKEN-READY

AMBIGUITY — REDUCE UNCERTAINTY WITHOUT WAITING FOR CERTAINTY

LPs: Bias for Action · Are Right, A Lot · Ownership · Deliver Results.

SPOKEN FRAMEWORK

"I separate unknowns from decisions. Every unknown goes into an assumption log with an owner, expiry date, impact if false, and the cheapest test. Discovery is staged: map the flow, test the highest-consequence seams, then deepen only where the decision depends on it. I decide reversible, bounded choices inside the approved guardrails. I escalate irreversible choices, cross-org priority, policy, customer exposure, or a risk above the agreed tolerance. That lets engineering move while leadership retains the decisions only leadership can make."

I decide alone

- Sequence of working sessions and discovery tests.
- Format and operating cadence of logs.
- Reversible work inside signed scope and budget.
- Issue classification against published definitions.
- When evidence is incomplete, a bounded experiment with switches and named blast radius.

I escalate for a decision

- Irreversible data or truth migration.
- Scope, architecture, policy, or peak-freeze change.
- Cross-org resource collision I cannot resolve with sequencing.
- Customer exposure above tolerance.
- Go / hold when evidence and business urgency conflict.

The assumption-log sentence

"I do not say 'we need more information.' I say: assumption, owner, expiry, cheapest test, consequence if false, and which decision it blocks."

S — Situation. UDC's architecture and FSD were not yet signed, but some upstream merchandising work had a long lead time and the integrated schedule could not absorb waiting for every downstream answer.

T — Task. Preserve speed without letting provisional work harden into an unapproved architecture.

A — Action. I split the plan by reversibility. MCS / FRAME work began June 9 as a fenced, reversible track. I documented assumptions and prevented the WMS-conversion, outbound, finance, and EDW tracks from opening until the council decision. The July 31 council then decided the target architecture and staged timeline; the FSD closed August 14.

R — Result. We did not lose the entire lead-time window, and the highest-blast-radius work stayed behind the gate. I also gained a reusable rule: start early only where rollback is cheap and the provisional boundary is explicit.

TRADE-OFF I MADE: I accepted rework risk on a reversible slice to protect schedule, and rejected at-risk starts for irreversible truth migration.

Proof story + number: UDC ambiguity — build began **June 9** before the **July 31** sign-off, fenced by reversibility (record-from-docs).

SAFE-SAY: "I did not start the whole build early; I allowed a bounded upstream slice while the higher-risk tracks stayed gated."
Source sentence: "Those dates and track boundaries are on the council timeline."

Failure / learning: The FSD still landed August 14. I now put assumption expiry and evidence owner directly on the integrated milestone, not only in the RAID log.

FRAMEWORK CARD 3 · SPOKEN-READY

STAKEHOLDER MANAGEMENT & COMMUNICATION — DIFFERENT VIEWS, ONE DECISION SYSTEM

LPs: Earn Trust · Ownership · Success and Scale Bring Broad Responsibility · Deliver Results.

SPOKEN FRAMEWORK

"I map stakeholders by what I need from them, what they need to trust, and how they consume evidence. Engineers get interface contracts, owners, test failures and decision deadlines. Operators get process changes, control screens, training prerequisites and fallback. Executives get metric, trend, driver and ask. I use the same underlying rows so those are views, not different truths. I escalate only when I need a decision, with options, recommendation, cost of delay and the date the decision expires."

WHO I NEEDED	WHAT I NEEDED	HOW I GOT IT	COMMUNICATION CONTRACT
Architecture / engineering	System owner per row; interface and nonfunctional acceptance; LOE; rollback path.	Owner-tagged requirement table, working sessions, design review, E2E matrix.	Weekly IT block; async decision pre-read; red = cause, owner, date.
Operations / business owners	Real process, test actors, control ownership, training and cutover readiness.	Flow walk-throughs, demos during build, dated E2E days, role-based runbook.	Weekly business block; readiness scorecard; cutover notices in operator language.
Finance / risk / security	Cost basis, policy constraints, access lead time, audit and reconciliation.	Early approver map, explicit review milestone, signed decision or exception.	Decision log and evidence appendix; no surprise at go/no-go.
Executive steering	Cross-org decisions, scope / date / risk trade-offs, go / hold.	One-page options and recommendation; rejected option remains visible.	Metric → trend → driver → ask; answer in the room, audit in appendix.

Escalation test

I escalate when: the decider is outside the team; the decision changes scope, policy, architecture, customer exposure, or shared priority; and the delay has a date. I do not escalate status, interpersonal discomfort, or a problem without a recommendation.

S — Situation. UDC crossed merchandising, WMS, digital, finance, reporting, HR, robotics, and distribution operations, each with a valid local optimization.

T — Task. Keep approximately two dozen named systems aligned without forcing every stakeholder into every meeting.

A — Action. I used a stakeholder map by decision and phase; separated the steering agenda into IT and business blocks; kept one RAID, requirement, decision, and issue grammar; pre-wired owners; and escalated the peak-freeze boundary as a decision with options rather than as a red status.

R — Result. The council received decision-ready material, E2E dates became shared commitments, and the staged go-lives completed with zero customer-facing incidents (record).

TRADE-OFF I MADE: I rejected one giant weekly meeting. Separate blocks reduced attendance cost, while the shared rows and join decisions prevented business / IT drift.

Proof story + number: UDC stakeholder system — **seven system families and about two dozen named systems** on one impact view (record-from-docs).

Failure / learning: A late FSD proved that communication frequency is not decision closure; I now end every forum with decision, owner, evidence, and expiry.

FRAMEWORK CARD 4 · SPOKEN-READY

COST VS SPEED — PRICE THE OPTIONS, THEN BUY REVERSIBILITY

LPs: Frugality · Bias for Action · Insist on the Highest Standards · Deliver Results.

SPOKEN FRAMEWORK

"I do not frame cost versus speed as cheap versus fast. My options page carries delivery speed, direct cost, operational risk, reversibility, cost of delay, and what evidence unlocks the next stage. The rejected option stays visible so leadership knows what we declined and can reopen it if conditions change. I prefer the fastest option whose failure is bounded and recoverable. Stage gates let us buy information before buying full scale."

DECISION	OPTION CHOSEN	OPTION REJECTED — REMAINS VISIBLE	HOW I PRICED IT	GATE
UDC launch shape	Two waves: upstream PO creation, then combined inventory / WMS release.	One big-bang truth and WMS change.	Chosen path carried interim-state operating cost; rejected path carried larger rollback radius and peak exposure.	Each wave had its own E2E and go/no-go evidence.
Inventory capacity	One comingle pool with channel reserves and a new selling identity.	Keep separate pools and add capacity around them.	Architecture / change cost versus ongoing space, transfer, and duplicate-truth burden; no invented dollar.	Council signs identity, reserve, and transition requirements.
JDA date	Hold the date only after three mocks earn tolerance.	Reduce rehearsal cadence to protect schedule optics.	Mock effort is visible; production recovery and customer exposure dominate the alternative.	Published 0.5% tolerance; mock three reached 0.3% (record).
Ambiguous build	Start a reversible upstream slice at risk.	Start every track, or wait for every signature.	Bounded rework versus total schedule delay; irreversible tracks stay gated.	Architecture council before high-blast-radius tracks open.

My five-column decision read

1. **Cost:** direct spend plus operating burden and rework.
2. **Speed:** earliest useful capability, not merely code complete.
3. **Risk:** probability × customer / operational blast radius, expressed plainly.
4. **Reversibility:** switch, rollback time, data restoration, and who can invoke it.
5. **Cost of delay:** customer, revenue, peak, or resource consequence by the next real decision date. If not sourced, I describe it without inventing dollars.

S UDC combined an inventory truth change with a WMS upgrade in a live building. **T** Protect peak and customer continuity without turning safety into indefinite delay. **A** I kept big bang on the options page, recommended two waves, preserved rollback boundaries, and required E2E evidence before each step. **R** Both go-lives completed with zero customer-facing incidents (record), and DC Ops measured +15% processing efficiency after stabilization (record).

TRADE-OFF I MADE: I bought safety with an interim state and its support burden; I rejected one faster date with a much larger recovery domain.

Proof story + number: RP→JDA — three mocks moved variance **7.0% → 1.8% → 0.3%** against a pre-published 0.5% tolerance (record).

Failure / learning: A date is not a benefit if readiness was silently removed to reach it; after G2, prerequisite tests are never traded away without naming the new risk.

PORTFOLIO VIEW · ONE PAGE

MY PROGRAMS AT A GLANCE

PROGRAM	SCALE	GATES	WHAT WENT WRONG	WHAT I CHANGED
UDC dual inventory + WMS Sephora · UDC B1	About 15 months; 44 requirements / 23 named systems; about 30 build tracks is a user anchor.	Discovery ownership; council decision; signed FSD; dated Inbound / Dotcom / Retail E2E; Blocker + Critical zero; cutover invariants; blockers/day for hypercare.	FSD planned Jul 26, signed Aug 14. Retail E2E planned Jan 15 and completed at end of January after Locus re-slot.	Put evidence owners and predecessor tests on milestones; staged two go-lives; read go/no-go and hypercare from counted rows.
RP→JDA migration Sephora · P2	Two DCs; eight months; about $1.8M budget, roughly 3% under (record).	Written phase entrance / exit; three mock cutovers; 0.5% tolerance; Blocker + Critical zero; rollback per interface.	I lacked a WMS-experience shortcut; the first mock was 7.0%, far outside tolerance.	Used gates instead of confidence; rehearsed to 1.8%, then 0.3%; made tolerance predate results.
Locus robotics Sephora · P3	Live UDC robotics transition; physical and system dependencies; full volume in week three.	98% quality gate; volume throttle; weekly read; retail retest after re-slot.	Week two reached 94%, below the 98% bar; retail testing slipped about three weeks.	Held volume rather than redefining quality; re-slotted transparently; increased only after evidence crossed the gate.
Crux transition Flexport · P4	79 customers; $185,892 ARR base; 294,581 annual containers (record-from-docs).	Apples-to-apples reliability baseline; destination owner and date per customer; residual backlog before decommission.	Raw 25% versus 63% comparison mixed different populations; normalization exposed a remaining variance problem.	Normalized first, then improved the residual; kept migration ownership separate from metric advocacy.
Canada managed bulk ship Sephora · UDC B2	About 13% volume; 99 planned brands in 20 / 40 / 39 waves; about 2.5M units front-load (plan, record-from-docs).	Discovery sign-off; business datasets; pilot / wave readiness; inventory transfer before sourcing flip; nightly-batch sequencing.	Post-launch outcome is absent from sources; I will not turn the plan into a result.	Speak to discovery deliverables and launch plan only; VERIFY how many brands moved and the operational outcome.
S/4HANA / ISM Bench only	One-line bridge; already told earlier in the loop.	Signed inventory policy, reconciliation, publish-only truth, governed overrides.	My first in-transit rule was too conservative.	Changed the policy through evidence and the same signatories; do not lead with this story today.

> **Portfolio close:** “Across these programs, the technology differs; the mechanism is consistent: one owned specification, evidence before each irreversible step, a rehearsed recovery path, and a close based on stability.”

Basis: record = Apple workbook / reconciled candidate record; record-from-docs = primary program artifact; user anchor = GFiber v8 only and should be qualified if probed.

ALL 16 LEADERSHIP PRINCIPLES

Use the exact story pointer; the Bar Raiser bank contains the full STAR answer and probing depth. AIQB citations refer to the Amazon Interview Question Bank.

LP / AIQB PROMPT	EXACT POINTER	STAR LANDING LINE	NUMBER
Customer Obsession AIQB: Customer Obsession Q6 — customer asked for something that would not address the need.	**R1** routing guide; backup **G1/F1** UAT crash.	S: carrier blame on weak data. T: find real need. A: measurement gate first. R: enforceable service.	~55% true → 99% DQ (record).
Ownership AIQB: Ownership Q1 — significant work outside responsibility.	**R5** trace ID; backup **G3/F2** security review.	S: six-system seam lacked tracing. T: own delivery seam. A: propose cross-team contract. R: faster recovery.	Blocker MTTR −50% (record-from-docs).
Invent & Simplify AIQB: Invent and Simplify Q5 — usual approach would not work.	**R2** carrier bid; backup **R7**.	S: "optimizer" problem was reconciliation. T: simplify. A: one lane master and rules. R: shorter cycle.	About 6 weeks → about 3 (user anchor).
Are Right, A Lot AIQB: Are Right, A Lot Q7.	**R5**; backup **F3** in-transit reversal.	S: bug location took hours. T: test my system hypothesis. A: per-hop evidence. R: time fell; or own reversal.	2–4 hours to locate; MTTR −50%.
Learn & Be Curious AIQB: Learn and Be Curious Q2.	**R7** LLM agent; backup **P3** Locus.	S: working demo was too costly. T: learn evaluation and routing. A: eval set, model tiers, citation rule. R: viable operation.	$25 → $0.40 / incident (record).
Hire & Develop AIQB: Hire and Develop the Best Q4.	**R9** QA lead; backup **R3** site super-users.	S: cadence lacked ownership. T: create leader, not compliance. A: QA owns gate. R: mechanism copied.	Four-week cadence in six weeks; critical defects −50% (record).
Highest Standards AIQB: Insist on the Highest Standards Q6.	**R8** issues log; backup **P3**.	S: many defects could become status noise. T: make closure auditable. A: severity, owner, evidence. R: safe release.	836 rows; 85.4% closed; zero customer incidents.
Think Big AIQB: Think Big Q1.	**R1**; backup **R9**.	S: Austria pilot. T: make reusable control. A: common data and Finance gate. R: scaled to 25 locations.	About $8M validated across 25 locations (record).
Bias for Action AIQB: Bias for Action Q8.	**R6** two programs; backup **P6**.	S: date pulled forward. T: preserve both. A: one ruler, two-pass handoff. R: both dates held.	Compressed launch inside four weeks (record).
Frugality AIQB: Frugality Q4.	**R7**; backup **R3**.	S: agent cost blocked scale. T: keep quality, cut unit cost. A: route easy work cheaply. R: viable cost.	98% cost reduction per incident (record).
Earn Trust AIQB: Earn Trust Q5.	**R4** ownership split; backup **G2**.	S: two orgs overlapped. T: resolve without turf win. A: one row per work item. R: written boundary.	15 items: 12 export / 3 import (record-from-docs).
Dive Deep AIQB: Dive Deep Q6.	**R5**; backup **R1**.	S: aggregate "system issue." T: find seam. A: events-in / events-out per hop. R: defect isolated faster.	2–4 hours before; MTTR −50%.
Have Backbone AIQB: Have Backbone; Disagree and Commit Q3.	**R6**; backup **R2**.	S: competing priorities. T: challenge false blockers. A: classify on one ruler. R: commit after decision.	Inside four weeks; original date held.
Deliver Results AIQB: Deliver Results Q1.	**UDC B1**; backup **P2**.	S: coupled live-building change. T: stage safely. A: gates and two waves. R: stable launch.	+15% efficiency; zero customer-facing incidents (record).
Earth's Best Employer AIQB: Strive to be Earth's Best Employer Q5.	**R6**; backup **R9**.	S: pulled-forward work risked burnout. T: protect people and dates. A: two-pass handoff, 45-minute forum. R: no 24-hour heroics.	45-minute forum (record).
Broad Responsibility AIQB: Success and Scale Bring Broad Responsibility Q1.	**R4**; backup **F3**.	S: local choice affected customer / partner system. T: own second-order effect. A: shared goals or governed reversal. R: safer whole.	15 work items; or oversell increase zero (user anchor).

INFRASTRUCTURE / PROGRAM PROMPTS

PROMPT	LEAD POINTER	STAR SPINE	PROBE / NUMBER
Largest program you ran	**UDC pack B1**	S coupled truth + WMS change in live DC. T own end-to-end operating system. A five gates, council, E2E, staged cutover, hypercare. R stable release.	About 15 months; 44 rows / 23 systems; zero customer incidents.
Deploy at scale	**P2 RP→JDA** backup R3	S two DCs. T migrate without experience shortcut. A written gates and three mocks. R both DCs migrated inside budget.	Eight months; about $1.8M; ~3% under; 0.3% final mock.
Trade off cost vs speed	**Framework 4 + UDC B1**	S big-bang was faster on paper. T protect peak and recoverability. A price two waves vs one. R zero customer-facing incidents.	Say interim-state cost; do not invent dollars.
Handle ambiguity	**Framework 2 + UDC B1**	S sign-off pending. T preserve lead time. A start only reversible upstream slice, fence high-risk tracks. R moved with bounded rework.	June 9 start; July 31 council; Aug 14 FSD.
Stakeholder conflict	**Framework 1 / UDC council** backup R4	S local optimizations conflicted. T one decision. A strongest objection into a row, price, named decider, commit. R buildable contract.	44 requirement rows / 23 systems.
Hold a go-live	**P3 Locus** backup G2	S quality below line. T protect operation despite schedule pressure. A throttle, do not redefine bar, retest. R full volume only after recovery.	98% bar; 94% week two; full volume week three.
Incident / hypercare	**UDC B1** backup P6 / R5	S production transition. T stabilize and close on evidence. A daily blocker burn-down, customer impact, reconciliation, control owner. R exit by blockers/day.	UDC issue burn-down and under-two/day bar are user-anchor detail; qualify.
Failure / missed deadline	**UDC B5** backup G2	S FSD date was mine. T recover without hiding slip. A expose cause, re-sequence, protect downstream gates. R signed Aug 14; mechanism changed.	Planned Jul 26; signed Aug 14 (record resolution).
Communicate to executives and engineers	**Framework 3**	S same program needs different depth. T preserve one truth. A one row set, role-based views; executive metric/trend/driver/ask. R faster decisions.	Seven families / about two dozen named systems.
Cutover mechanics	**P2** then UDC B1	S irreversible switch. T make live event routine. A owner-duration-predecessor runbook, mocks, checkpoints, trigger-based rollback. R earned go.	Three mocks; 0.5% tolerance.

Fast Bar Raiser backups

Disagreed with manager: R6 — one ruler, then commit.

Influenced without authority: R4 — one owner per work item.

Simplified a process: R2 — lane master before solver.

Developed someone: R9 — QA owns the gate.

Changed mind with data: F3 — in-transit policy reversal.

Tight timeline: R6 — pulled forward one month.

Learned a new domain: R7 or P2.

Quality conflict: P3 — 94% did not become “close enough.”

Router rule: Start with the direct answer, then S/T/A/R. Land one number and stop. If Rocky asks for depth, add the decision mechanism or failure—never another list of project facts.

QUESTIONS TO ASK ROCKY

1. **Infrastructure deployment cadence:** “How does your organization balance a fixed infrastructure release cadence with application teams that have different readiness and rollback constraints?”
2. **Shared launch / peak-freeze calendar:** “Where do Infrastructure and Supply Chain jointly own the launch calendar and peak-freeze boundaries, and where do you see handoff friction today?”
3. **Design review:** “When a program manager comes into one of your design reviews, what do you most want them to bring beyond schedule—options, operational readiness, dependency evidence, or something else?”
4. **Holding go-live:** “When business urgency and an engineering readiness signal conflict, what evidence most often causes you to hold a go-live?”

VERIFY — safe sentences

ITEM	WHAT IS VERIFIED	SAFE SENTENCE TO USE
Canada outcome	Discovery scope, planned dates, 99-brand waves, about 2.5M-unit front-load, and Rajesh named as PM are in the deck. Post-launch outcome is absent.	“At discovery exit, we had a signed plan for 99 brands in three waves. I would verify how many brands actually moved and the operational result before claiming it.”
UDC systems count	Primary deck: seven families, about two dozen named systems; requirements table: 44 rows across 23 named systems. Earlier spoken shorthand says about a dozen domains.	“The council deck names about two dozen systems in seven families; when I say about a dozen, I mean operating domains, not a literal system count.”
UDC build tracks	About 30 tracks is a candidate / GFiber user anchor, not directly counted in the council deck.	“My working plan had about 30 tracks; the primary deck independently supports 44 requirements across 23 named systems.”
UDC hypercare bar	Issue burn-down is record-from-docs. Under two blockers per day and exit week three of four are user anchors.	“I used a sustained blockers-per-day exit bar; the exact under-two threshold is from my program record and I would confirm it if exactness matters.”
Locus 94% / week three	Gate shape is reconciled; part of the detail is candidate record / user anchor.	“The rule was a 98% gate; at 94% I throttled rather than redefining the bar, and full volume followed after recovery.”
Crux result boundary	79 customers, $185,892 ARR base, and 294,581 annual containers are transition-document facts. ARR is the legacy base, not a one-period loss.	“The transition document records 79 customers and $185,892 of annual recurring revenue in the legacy base; I do not claim that entire amount was lost.”

SAFE-SAY BANK

Ownership

“I built the operating system—requirements, gates, cadence, decision path and go/no-go recommendation. Architects owned component design; engineers built and tested the code.”

Numbers

“I will distinguish primary-document facts, my reconciled program record, and user anchors. If the source only proves a plan, I will call it a plan.”

Failure

“The planned date was mine. I will not blame the approver; I failed to put the predecessor evidence and owner on the milestone early enough.”

Close

“The common thread is not supply-chain analysis. It is governing coupled engineering change so every irreversible step is earned by evidence and every release has a recovery path.”

20-SECOND VERSION

> “I am a program leader who turns cross-system ambiguity into an owned specification, gates build with end-to-end evidence, and runs cutover and hypercare from counted rows. UDC is the proof: 44 requirements across 23 named systems, staged go-lives, and zero customer-facing incidents. My misses—late FSD and the RF-device dependency—are why predecessor evidence and rollback are now explicit on every plan.”

Primary companions: UDC/Canada story pack B1/B2/B5; Rocky program stories P2–P4; Rocky Bar Raiser bank R1–R9 and F1–F4; Apple delta G1–G3. Basis vocabulary: record · record-from-docs · user anchor.

Part 3C — Rocky Goforth — program-management STAR stories

10:00 AM PDT, Fri Oct 30 · Sr Manager, Amazon Infrastructure · also the Bar Raiser

Scope: three full SDLC / large-deployment program stories — cadence, gates, stakeholders, cost-vs-speed trade-offs. No detailed math. Rajesh Rishiyur Chandrasekaran · Amazon NACF Supply Chain, Sr Supply Chain Manager (L6).

> **How to use this part.** His ask: an engineering / program leader who runs large-scale deployments on a cadence, manages stakeholders and trades cost against speed on purpose. Each story below is a full program: **60-second pitch → S / T / A / R in first person → five gated phases (entry · delivered · exit) → who I needed / what / how → TRADE-OFF I MADE → failure / learning → LP tags → SAFE-SAY → 20-second version → 4 probing Q&As**.
> **Basis labels: record** = Apple v11 workbook / resume; **record-from-docs** = a page or row of an uploaded source document; **user anchor** = GFiber v8 only (confirm before saying the exact figure); **my division** = arithmetic I did, never banked.
> **Not repeated here (already told Thu to Snigdha / Ryan):** S/4 HANA / ISM, Flexport estimation / FF App, Shipment Visibility, safety stock, 200-lane. One-line bridges only.

CONTENTS

Framework — how I run a program: cadence and a five-question cost-vs-speed framework (one page).

P2 — RP → JDA WMS migration across two DCs (Sephora): eight months, on time, about 3% under a ~$1.8M budget; mocks 7.0% → 1.8% → 0.3% against a 0.5% line; RF-device miss inside it.

P3 — Locus robotics deployment, Salt Lake City DC (Sephora / UDC program): vendor SOW, wiring install, change control, 94% vs a 98% readiness gate with a throttle, full automation in week three, the RTL slip.

P4 — Crux transition plan (Flexport): retiring a legacy visibility platform for 79 customers — parity, shadow accounts, cutover waves, comms, owner decisions, what we did not carry over. *Program / cutover lens only.*

Pointers (not rewritten here) — UDC dual inventory end to end, Canada bulk-ship plan, FSD-slip failure: *amazon-nacf-udc-canada-story-pack-star-kimi-k3* (B1, B2, B5). More stories, failures F1–F4, 32-answer LP bank: *amazon-nacf-panel-3-goforth-bar-raiser-bank-star-kimi-k3*.

> **Opening line for Rocky (say it once):** “I run programs as gated lifecycles — every phase has a written entry and exit, the pass line is published before the data arrives, and I trade cost against speed explicitly, in writing, with the owner of the money in the room.”

How I run a program — cadence and the cost-vs-speed framework (one page, say it in under a minute)

> **IF HE ASKS "HOW DO YOU RUN A LARGE PROGRAM?" — 45 SECONDS**
>
> I run every program on the same machine. First, baseline the number before touching anything. Second, one scorecard on a fixed cadence with the same definitions every week — two dashboards is zero dashboards. Third, stage gates with numeric entry and exit criteria, published before the data arrives, so the gate can actually stop the program. Fourth, when a number goes red, I chase it to the root cause before spending money on the symptom. Fifth, the correction lands in the same weekly review that surfaced it, with an owner and a date. Every story I'm about to tell is that machine applied — two DCs, a robotics deployment, and a platform retirement.

Source: Apple v11 workbook, Part 0 "How I run a program" record.

PROGRAM CADENCE — WHAT I ACTUALLY RUN

RHYTHM	WHAT IT IS	WHERE IT SHOWS UP
Daily	Blocker count / bug triage in stand-up; hypercare blockers against a written exit	P2 hypercare (under two blockers a day); P4 shadow-account bugs read daily
Weekly	One cross-functional review — RAID or track status — the worst number said out loud by me, with owner and date	P2 weekly RAID; P3 Locus retail-track status inside the program's two-block weekly; P4 wave readiness
Per gate	Entry and exit criteria on paper; the gate reads the scorecard, not confidence	P2 mock scorecards and UAT entry; P3 98% robotics gate; P4 80% minor-to-no-issues shadow bar
Steering	Decisions with prices: slips, scope fences, re-slots — the week they surface	P3 three-week re-slot; P4 RAPID decision per segment

MY COST-VS-SPEED FRAMEWORK (FIVE QUESTIONS I ASK BEFORE I TRADE)

QUESTION	WHAT IT DECIDES	EXAMPLE
1. What does a slip cost, in the money owner's terms?	How much I will pay to protect the date	P2: a $20M pipeline of four projects waited on the date
2. What defect class does going faster add?	Whether compressing a phase is really cheaper	P3: a compressed UAT is a defect class I would own at go-live — I re-slotted instead
3. Is the step reversible?	Pay for reversibility only where the step can't be undone	P2: 72-hour freeze, RP read-only 30 days, rollback per interface
4. Can I make it a dial instead of a switch?	Partial speed instead of all-or-nothing	P3: bot-vs-cart share was a parameter — 30% throttled for a week
5. Can I segment instead of setting one date?	Move fast where the fit is clean, slow only where needed	P4: migrate, partner, API or cancel per segment, not one shutdown

> **The rule under all five:** the trade is written down, with its cost, in front of the person who owns the money — before the pressure arrives. A trade made quietly in a weekend is not a trade; it is a hidden risk.

P2 — RP → JDA WMS migration across two DCs: eight months, on time, about 3% under budget FULL STAR

Company: Sephora (two distribution centers) · **My role:** program lead, full SDLC owner · **Team:** 14 core + 6 DC Ops record
Why Rocky: a large deployment run outside my expertise on gates, cadence and a published pass line — the cleanest "program management play" I have. **LP tags:** Deliver Results · Insist on the Highest Standards · Ownership · Earn Trust.

60-SECOND PITCH

At Sephora two distribution centers had to move from an old RP system to JDA WMS in eight months, with a twenty-million-dollar pipeline of four strategic projects waiting behind the date. I had never run a WMS migration and nothing was documented. So I ran gates instead of experience: discovery, design, build, test, cutover and hypercare, each with a written entry and exit, and no phase opened until the previous exit was signed. The pass line for data accuracy — half a percent — was agreed with Finance *before* the first mock cutover. Mock one came back at 7%, mock two at 1.8%, mock three at 0.3%, and the go-live recommendation cited that scorecard, not confidence. We went live on time, about 3% under a roughly $1.8M budget, and hypercare met its written exit in week three of four. The one miss inside it — an RF-device script that moved training a week and a half — is the reason every dependency I own now has a what-if plan.

S — Situation. Sephora, two DCs on a legacy RP warehouse system, a hard eight-month deadline to JDA WMS, and a $20M pipeline of four strategic projects that could not start until the migration landed record. No strategy, scope, milestones, dependencies or risks were written down when I was handed it.

T — Task. I owned the program end to end: deliver on time, on budget (about $1.8M record), with cutover data accuracy *proven* before go-live — and run it as a full lifecycle, not a technical swap.

A — Action. I sat with the sponsor first on objectives, assumptions and success criteria; turned the lifecycle into five gated phases (below); ran one weekly cross-functional RAID review as the program heartbeat; published the 0.5% reconciliation tolerance with Finance before mock one; gave every miss class an owner; and wrote the go-live recommendation off the scorecard. The JDA configuration was the team's; the governance that made three honest mocks possible was mine.

R — Result. On time; about 3% under a ~$1.8M budget (roughly $54K — my division); mocks 7.0% → 1.8% → 0.3% against the 0.5% line; the 72-hour in-transit freeze held; hypercare exited on "under two blocker tickets a day" in week three of four; the $20M pipeline started the month after record.

ACTION — FIVE GATED PHASES (ENTRY · DELIVERED · EXIT)

PHASE	ENTRY (WHAT HAD TO BE TRUE)	DELIVERED	EXIT (WRITTEN, SIGNED)
1 Discovery	Sponsor objectives, assumptions and success criteria agreed one-to-one	Documented current state for every flow; scope, milestones, governance, risk register	Every call-out addressed — I held this gate even though it was the phase everyone wanted to rush
2 Plan & design	Discovery exit signed	Leads walked every milestone's dependencies; designs taken through the architecture council; stories ranked by criticality	Design sign-off; criticality-based build order agreed

PHASE	ENTRY (WHAT HAD TO BE TRUE)	DELIVERED	EXIT (WRITTEN, SIGNED)
3 Build	Signed designs; criticality order	Criticality-based build; QA demoing to DC Ops as features landed; dotcom and retail conversion build finished inside the phase	UAT entrance criteria met: function testing done, conversion build done, test data handed off, pre-prod and performance environments ready — “UAT opened on proof, never on promises”
4 Test & mock cutovers	UAT exit; 0.5% tolerance published with Finance **before** mock one	Three full dress rehearsals at production volume: item, location, inventory masters and open orders, every record pair a match or a counted miss by defect class	Mock three at 0.3% ≤ 0.5% → written go-live recommendation citing the scorecard; device readiness proven (after the RF miss)
5 Cutover & hypercare	Go-live recommendation accepted; runbook = mock-three timings	72-hour in-transit freeze; rollback per interface; RP kept read-only 30 days for failback; four-week hypercare schedule	Under two blocker tickets a day — hit in week three of four; pipeline released

WHO I NEEDED · WHAT · HOW I GOT IT

WHO	WHAT I NEEDED FROM THEM	HOW
Executive sponsor	Success criteria; air cover to hold the discovery gate	One-to-one first, before any plan; the exit criteria on paper so the hold was a rule, not my opinion
Finance partner	A pass line both of us would honour under pressure; budget actuals	Agreed 0.5% in writing before mock one; Finance owned the actuals against the charter
DC Ops leads (6 on the program)	SME time, training windows, acceptance of a 72-hour freeze	QA demos as features landed so Ops saw progress early; freeze and read-only fallback framed as their insurance
Engineering / JDA configuration team	Owners for each miss class; scripted reconciliation extracts	Defect classes with one owner each, re-verified in the next mock; the weekly RAID with the worst number said by me
Devices / infrastructure team	RF guns, printers and workstations converted before training	After the miss: device readiness written into training’s entry criteria — proven devices, not promised ones

TRADE-OFF I MADE — COST VS SPEED

Options. (a) Compress discovery and overlap build to buy calendar against a hard date; (b) hold every gate and pay for reversibility at cutover.

Chose (b). I spent schedule and political capital holding discovery until every flow was documented, and I made the business accept operational cost — a 72-hour in-transit freeze and 30 days of RP read-only — so no flow was irreversible.

Rejected (a) because a skipped discovery shows up as a mock-three surprise, and a slip on this date stalled the whole $20M pipeline — about $2.5M a month on average my division, not banked . Cost of my choice: freeze pain for the DCs and a hard few weeks defending the hold.

Failure / learning (Apple G2, told honestly). Training sign-off was a go-live exit criterion that depended on **hundreds** of RF guns, printers and workstations converting. The devices team called it three to four days; I planned it as low effort. I scheduled a device test before training anyway — the upgrade script failed on newer RF hardware. With key people on COVID night shifts, manual conversion could not finish in time, so I told leadership straight: training moves 1.5 weeks, my miss. **Go-live held.** Root cause was my risk model — I sized by effort, not impact. Since then every cross-functional dependency gets a what-if line (what breaks, who owns the fallback, how long it takes).

Deliver Results — eight months, on time, about 3% under, with the $20M pipeline released the month after.

Insist on the Highest Standards — the 0.5% pass line was published before any data could pressure it.

Ownership — I owned a program outside my expertise, and owned the RF miss out loud.

Earn Trust — mock one's 7% went to leadership unvarnished, with my name on the note.

> **SAFE-SAY**
>
> **Most attackable number:** "The devices were in the hundreds — the 2022 write-ups count the fleet differently, so I say hundreds; the facts that matter are that the test ran before training, training moved a week and a half, and go-live did not move."
>
> **"What's your source?"** "The program charter and my go-live recommendation: eight months, about $1.8M and roughly 3% under, and the three mock scorecards at 7, 1.8 and 0.3 against a half-percent line agreed with Finance before mock one."

> **20-SECOND VERSION**
>
> "Two Sephora DCs from RP to JDA in eight months, a $20M pipeline behind the date, and I had never run a WMS migration. I ran it as five gated phases, published a half-percent accuracy line with Finance before the first mock, burned 7% down to 0.3% over three mocks, and went live on time and about 3% under budget."

PROBING Q&A

Q1. You set the 0.5% yourself and passed at 0.3% — isn't that grading your own exam?

The line was agreed with Finance, in writing, before mock one — the opposite of negotiating under pressure. A rehearsal passing inside a pre-agreed line is what rehearsal is for. Zero-defect cutovers don't exist; the remaining tail was documented, priced and accepted by the business.

Q2. What was your program cadence, concretely?

One weekly cross-functional RAID review as the heartbeat — risks, actions, issues, decisions, with owners and dates; phase-gate reviews with the sponsor at each exit; a mock every rehearsal cycle with a scorecard readout; daily blocker counts in hypercare against the "under two a day" exit.

Q3. What was in mock one's 7%?

Mostly vocabulary, not loss: unit-of-measure mappings, location naming that had drifted, and open-order status codes that meant different things in RP and JDA. Counted by class with an owner each, so the rate fell predictably. Learning: I'd now reconcile a thin sample before mock one — vocabulary classes surface on a small sample weeks earlier.

Q4. What would you do differently?

Put the discovery exit criterion in front of leadership on day one, before calendar pressure arrived — holding discovery was right, but publishing what "done" meant earlier would have made the hold cheaper to defend. And the what-if line per dependency from kickoff, which would have turned the RF failure into a non-event.

> **Do not attach** the 343-task runbook to this story — 343 timed tasks is the UDC dual-cutover plan (May–Jul 2025), used in P3. Here the runbook is "mock three's timings." Never speak a cost multiplier for the fallback.

P3 — Locus robotics deployment at the Salt Lake City DC: vendor SOW to full automation in week three FULL STAR

Company: Sephora, Utah DC (UDC) in Salt Lake City · 2024–25 · **My role:** program owner for the robotics workstream inside the UDC conversion (BlueYonder WMS upgrade + dual inventory) · **Partners:** Locus (bots, LocusNet software, access points), a wiring vendor under the SOW, Sephora IT / WMS engineering, DC Ops.
Why Rocky: a large physical deployment with a vendor — network, hardware, software, integration, go-live — landed inside a live system conversion, on a published gate. **LP tags:** Insist on the Highest Standards · Bias for Action · Deliver Results · Earn Trust.
Angle rule: the full UDC dual-inventory program is UDC pack B1; the slip told as a failure is Bar Raiser bank F4. This story is the *deployment*: vendor scope, readiness gates, throttle, communication.

60-SECOND PITCH

At Sephora's Salt Lake City DC we added Locus robots to retail outbound in a building that was changing its warehouse system at the same time. My job was to land the robotics without adding risk to the conversion. I ran it as five readiness gates — physical, hardware, software, integration, then testing and go-live — and the network expansion went through a written SOW: two new network closets, thirty-one new access points and a fiber ring, with photo evidence before anything powered on. Before a single bot took volume I published the gate: 98% pick-accurate throughput, with manual carts planned as the fallback and the bot-versus-cart split built as a dial. When retail testing slipped three weeks, I re-slotted it openly and refused to compress UAT. In week two of go-live we measured 94%, so I throttled about 30% of volume to carts while the zone logic was fixed, and we were fully automated in week three — with zero customer-facing incidents through the combined go-live.

S — Situation. The UDC conversion carried a Locus robotics rollout for retail outbound — bots picking in a building also moving warehouse systems mid-flight. Locus design and build ran July–December 2024; physical testing February–March 2025; combined go-live May 2025 record. The site was an *expansion*: an existing Locus rack, but new coverage needed for the expanded floor record-from-docs, SOW v1.4.

T — Task. Land pick-accurate robotic throughput at go-live and protect the program's zero-customer-incident bar; coordinate a vendor, a wiring contractor, IT and DC Ops without letting robotics become the program's noise.

A — Action. I set the go/no-go gate before the bots arrived (98% pick-accurate throughput, 99% stretch); ran discovery as three working days of workshops with Locus, not email; tracked the work on one Locus retail-track status page across five readiness categories with a YELLOW/GREEN program status; put the network expansion under a versioned SOW with a physical checklist; escalated the retail-testing slip the week it surfaced; and made the week-two throttle call.

R — Result. Full automation by week three; retail outbound went live with the combined cutover and zero customer-facing incidents record; Locus-side issues held to 86 of the program's 836 logged rows, about a tenth record; DC Ops measured +15% processing efficiency on the converted building record — DC Ops' own measurement, whole UDC program.

ACTION — FIVE GATED PHASES (THE LOCUS RETAIL TRACK'S OWN CATEGORIES)

PHASE	ENTRY	DELIVERED	EXIT
1 Physical readiness	Site layout design workshop with Locus; three-day discovery agenda agreed	Bot map, travel paths, unreachable locations, pick / induction / drop-off zones, charger locations and electrical timing; site set-up (electrical, guardrails)	Site set-up complete; layout signed by DC Ops and Locus

PHASE	ENTRY	DELIVERED	EXIT
2 Hardware & network	SOW v1.4 issued (Nov 19, 2024) to the wiring vendor	Two new network closets (IDF3, IDF4) plus wiring to IDF1; 31 new access points (APs 19–49), each dual-cabled — 62 Cat6 runs — hung at about 35 ft with labelled backboards; three fiber runs closing a ring back to the main rack; existing rack and servers reused	Photo evidence of rack, closets and APs; rule “do not power on switches until physical fiber is connected”; bots and components delivered; Locus points installed and mapped
3 Software readiness	IT design checklist; WMS design scenarios (prioritization, cancelling)	LocusNet install and configuration; decisions logged: sockets rather than REST for the API; retail customer-owner configuration (SEPHORA-RTL) versus global variables	Design decisions closed on the track, owner named
4 Integration readiness	Interfaces unit-tested with simulated data before a physical bot rolled	System integration test; Locus mapping data uploaded; tote-type mapping and a base-36 outbound carton-ID request to Locus; WMS-to-bot end-to-end test	Retail E2E complete — planned January 15, completed end of January after the three-week re-slot
5 Testing & go-live	UAT window pencilled Feb 28–Mar 15; physical floor testing Feb–Mar 2025	UAT held at full length; the 98% gate counted weekly; bot-vs-cart share as a dial; go-live inside the combined cutover (343 timed tasks, about 815 task-hours, May 1–Jul 1, 2025)	Week 2 = 94% → ~30% throttled to carts → zone-logic fix → full automation week 3

WHO I NEEDED · WHAT · HOW I GOT IT

WHO	WHAT I NEEDED	HOW
Locus (vendor)	Zone design, LocusNet config, API agreement, the zone-logic fix	Three-day working workshops; decisions written on the shared track; I refused “ramp to 100% on our say-so” — the gate was published first
Wiring vendor	Closets, AP cabling, fiber ring installed to spec	A versioned SOW with a checklist per area and photo evidence as the acceptance test
Sephora IT / WMS engineering	Integration build, carton-ID and tote mapping, SIT	One status page, one Jira dashboard; owners per open item; simulated-data SIT before physical bots
DC Ops	Floor time for testing, labour for the cart fallback, trust in the throttle	The gate and the dial were theirs before the ramp, so when week two read 94% “the rule fired; I didn’t improvise”
Steering / sponsors	Acceptance of a three-week re-slot	Escalated the week the slip surfaced, with re-slotted dates attached, in the same forum as every other decision

TRADE-OFF I MADE — COST VS SPEED

Twice. (1) When retail testing slipped three weeks: compress UAT and keep every date, or re-slot openly and keep UAT at full length. (2) In go-live week two at 94%: keep full robot volume and fix live, or throttle to carts.

Chose the re-slot and the throttle. **Cost:** three weeks of float off the chain, an uncomfortable steering update, and about a week of manual-cart labour on roughly 30% of retail volume.

Rejected the faster options because a compressed test window is a defect class I would have owned in May, and a 94% system carrying full volume into a combined go-live is how you get a customer-facing incident with a robot in the photo.

Failure / learning. The retail-testing slip sat on my plan as a *task with a date*, not on the risk register with a trigger and an owner, so I learned it from a status report — the full telling is Bar Raiser bank F4. Second learning: the zone contention was findable with the bot map on the floor before live volume exposed it; I would now run physical zone testing earlier in the design window.

Insist on the Highest Standards — the 98% gate was published before the bots arrived, and it actually stopped the ramp at 94%.

Bias for Action — the throttle was pre-built as a dial, so the week-two call took minutes, not a meeting.

Deliver Results — full automation in week three, zero customer-facing incidents through the combined go-live.

Earn Trust — the vendor slip went to steering the week it surfaced, with dates, not absorbed into weekends.

> **SAFE-SAY**
>
> **Most attackable number:** "94 against 98 is the record from week two; about 30% of volume went to manual carts for roughly a week. The +15% processing efficiency is DC Ops' measurement for the whole converted building, not a robotics-only number."
>
> **"What's your source?"** "The Locus network SOW, version 1.4 dated November 19, 2024; the Locus retail-track status page; the program issues log — 86 of 836 rows were Locus-side; and the cutover plan, 343 timed tasks."

> **20-SECOND VERSION**
>
> "I deployed Locus robots into Sephora's Salt Lake City DC while the building changed warehouse systems. Five readiness gates, a versioned wiring SOW for 31 new access points and two new closets, a 98% gate published before the bots arrived. Week two read 94, I throttled 30% to carts, and we were fully automated in week three with zero customer incidents."

PROBING Q&A

Q1. Why 98% and not 100%?

100% is a fantasy bar that teaches teams to hide misses; much below the high nineties is a manual process with robots for decoration. The bar sat where the building's accuracy promise to stores lives. The point was that the number could stop the rollout — and it did, at 94.

Q2. What was actually wrong in week two?

Zone logic. The bot map and the induction rules disagreed about which zone owned which work, so bots were routed into contention. Locus drove the fix with our WMS engineers; the throttle bought the time to find it. Not a hardware problem — the network SOW and photo checks had done their job.

Q3. How did you run the vendor and the SOW — what was your cadence?

One retail-track status page with a program colour, five readiness categories, an action-item table with owner and due date, and a Jira dashboard behind it, read weekly inside the program's two-block status. The SOW was the physical scope baseline — it was at version 1.4 when the expansion was specified — and acceptance was evidence: photos of the rack, closets and access points, fiber connected before switches powered on.

Q4. Whose fault was the slip, and what did you change?

The slip came from the vendor-and-integration track; how I carried it was mine — a task, not a risk. Now every vendor dependency on the critical path goes on the risk register with a trigger date and a named owner on both sides, and a slipped vendor doesn't get to lower the bar. VERIFY the vendor-side root cause of the slip — safe sentence: "The integration items open at the time were the API style, the customer-owner configuration and tote mapping; I won't pin the slip on one of them."

P4 — Crux transition plan: retiring a legacy platform for 79 customers, segment by segment FULL STAR

Company: Flexport, 2021–22 · **Legacy platform:** Crux (track-and-trace service; engineering run by an offshore contractor) · **Destination:** the new visibility platform, the Transmission partner channel, the API, or a planned cancel.
My role: the program lens — turning the RAPID decision into a cutover plan: a destination and a date for every customer, shadow accounts before exposure, wave gates, communication and commitments. Decision rights sat with others (Recommend and Perform: the product leads who owned the transition plan; Agree and Decide: two executives) record-from-docs, RAPID p1 VERIFY my named role .
Angle rule: Rocky gets the *program / cutover* lens only. Venkata gets the product lens; James gets the reliability comparison (25% vs 63% normalized). Do not retell the 7 → 68 customer growth here — that was told Thursday. **LP tags:** Ownership · Earn Trust · Deliver Results · Are Right, A Lot.

60-SECOND PITCH

At Flexport we were retiring a legacy visibility platform, Crux, that still served 79 paying customers — about $186K of annual recurring revenue and close to 295,000 containers a year. The goal was to move Crux clients onto the new platform by the end of 2022, but most of Crux's revenue came from customers who were not Flexport trade clients and could not simply be moved. So I ran the retirement as a cutover program, not a shutdown date. Every one of the 79 customers got a destination and a date: trade clients migrated to the new platform in waves, two carriers and brokers were offered a partner path, forwarders and 3PLs got the existing API with no new build, and two software competitors were cancelled. Before any customer saw the new product, we ran shadow accounts on named Crux customers using their own data, with an 80% minor-to-no-issues bar. The decision went through a RAPID, every impacted owner committed in writing, and we said clearly what we would *not* carry over.

S — Situation. Crux had 79 customers across nine segments: 2 global key accounts, 14 enterprise and 39 SMB trade clients, plus 9 motor carriers, 3 truck brokers, 5 forwarders, 1 customs broker, 4 3PLs and 2 supply-chain SaaS companies — $15,491 a month, $185,892 a year, 294,581 containers in 2021 record-from-docs, RAPID p3–5 . About 75% of Crux revenue came from non-trade customers who could not use the client-app product as a replacement record-from-docs, 2021 Product Development Plan §5.4.3 . Running two platforms meant two cost bases and two versions of the truth.

T — Task. Retire Crux without a bad customer experience — "ejecting customers is never a good experience," as one stakeholder wrote in the RAPID — on the end-of-2022 target, with no customer left without a written path.

A — Action. I put the decommission on the risk register as the top risk, with an owner and a date; worked with the transition-plan owners to give every customer a destination and a date; ran shadow accounts and wave gates before exposure; pushed the open stakeholder questions (cost to keep Crux running, the feature gap, what happens to cancelled customers) into the decision record; and made the Inform and Commitments steps explicit so each impacted party committed in writing.

R — Result. The decommission went through on evidence: all 79 customers and 294,581 annual containers had a per-segment path — grow, partner/white-label, API, or cancel record, Apple A4 . Cancellations were dated in the record (the customs broker on September 1, 2022; one SaaS on August 1 after legal review; the other on October 24, 2022) record-from-docs, RAPID appendix . Trade clients rode the wave plan, with the remaining Crux clients scheduled for the H2 2022 full roll-out record-from-docs, Pilot Roll-out Schedule .

ACTION — FIVE GATED PHASES (ENTRY · DELIVERED · EXIT)

PHASE	ENTRY	DELIVERED	EXIT
1 Inventory & segment	Retirement target set (Crux clients to the new platform by end of 2022)	Customer-by-type table: count, MRR, ARR and 2021 containers for all 79; appendix listing every company and its churn status	Every customer in exactly one segment; revenue and volume concentration visible (two truck brokers carried most of both)
2 Parity & options	Segment table signed	Per-segment options: migrate, partner channel, API, keep on Crux while gaps are closed, or cancel; the parity bar written as data quality “at least as accurate as Crux” 90%+ of the time; known gaps named (e.g. manual container search)	A recommendation per segment written into the RAPID
3 Decide (RAPID)	Recommendation and stakeholder input collected — seven named input roles	Input answered in the record: cost of running two systems, the earlier “Crux Absorption” effort, feature gap, partner status of each broker	Decision by segment; the transition-plan owners commissioned to build per-segment plans and review them with the exec team
4 Prove before exposure	Decision signed	Shadow accounts: Crux customers’ own container data fed into dedicated Flexport demo accounts, starting with Marc Fisher and Michelin; bugs in Jira, read in daily stand-ups	80% minor-to-no-issues before customer-facing testing; wave graduation criteria met
5 Cutover waves & wind-down	Shadow and UAT gates passed	Trade clients in waves (Wave 3 mixed Crux and non-Crux clients; remaining Crux clients in the H2 2022 full roll-out); partner offers to brokers; API path to forwarders and 3PLs; dated cancels	Each customer migrated, partnered or cancelled on its date; Inform list and written commitments closed

WHO I NEEDED · WHAT · HOW I GOT IT

WHO	WHAT I NEEDED	HOW
Decider and Agree role (exec)	One decision per segment, not one decision for Crux	A RAPID with the segment table and a recommendation for each; decisions recorded per segment
Transition-plan owners	A per-customer plan and exec review	The decision named them as performers; I built the destination-and-date view with them
Trucking / Transmission team	A partner path for brokers instead of a cancel	Partner status checked customer by customer (one broker was already a partner); offer framed “similar to” that existing partner
Engineering and QA	Shadow accounts on real Crux data before any customer saw the product	Named starting customers, a staging-then-production environment plan, Jira bugs triaged daily
Legal and everyone on the Inform list	Clean cancels for competitor-adjacent customers; one shared list	Legal review before one cancel; dated cancels in the appendix so everyone worked from the same list

TRADE-OFF I MADE — COST VS SPEED

Options. (a) One shutdown date for all of Crux — fastest and cheapest to run; (b) build parity for every segment first — for example, tracking non-Flexport containers in the partner product — before retiring anything; (c) segment it: migrate the customers the new platform fits, offer existing channels to the rest, cancel where the customer is a competitor, and carry nothing new.

Chose (c). Rejected (a) because ejecting 79 paying customers on one date damages trust and leaves forwarders and brokers to a competitor; rejected (b) because building new capability for non-trade customers would have kept two platforms running past the target. **Cost:** we accepted that part of the $185,892 legacy base would be cancelled rather than migrated, and the decision record names what we would not build — non-Flexport tracking in the partner product: “we will not do so at this time.”

Failure / learning. A stakeholder's question in the RAPID — "what are the missing features between Crux and SV… is that written down somewhere?" — showed the feature-gap view was not in front of the decision makers before the meeting. I now write the parity view and the cost of keeping the legacy system running *before* the decision document circulates, so the room decides instead of asking.

What we did not carry over (say it plainly): no tracking of non-Flexport containers in the partner product "at this time"; no additional build for forwarders, customs brokers or 3PLs — the existing API or a cancel; no service for the two supply-chain SaaS companies; and no manual container search in the developer portal plan of 2021.

Ownership — I treated the retirement as the program's top risk, with an owner and a date, not as someone else's clean-up.

Earn Trust — every customer had a written path and date; stakeholder objections were answered in the record, not around it.

Deliver Results — all 79 customers and 294,581 annual containers had a destination; cancels are dated in the record.

Are Right, A Lot — segment decisions used partner status and revenue concentration, not a blanket rule.

SAFE-SAY

Most attackable number: "$185,892 is the documented annual recurring revenue of the legacy base at the decision — not a claim that we lost that amount; most trade clients moved to the new platform."

"What's your source?" "The RAPID for the Crux customer transition — a segment table of 79 companies with MRR, ARR and 2021 containers, the per-segment decisions and a dated appendix — plus the pilot roll-out schedule and the product-testing approach for the shadow accounts."

20-SECOND VERSION

"I ran the retirement of Flexport's legacy visibility platform as a cutover program: 79 customers, about $186K of ARR, each given a destination and a date — migrate, partner, API or cancel — through a RAPID, with shadow accounts on real customer data before anyone was moved, and a plain list of what we would not carry over."

PROBING Q&A

Q1. Why not just switch Crux off on one date?

Because most of the revenue sat with customers the new platform did not fit — brokers and carriers. A single date would have handed them to a competitor and broken trust with the rest. Segmenting let us move fast where the fit was clean — the SaaS competitors were cancelled in 2022 — and slow down only where a partner path existed.

Q2. How did you decide who to cancel?

By segment and partner status, written in the RAPID. One broker was already a partner, so the other two were offered the same partner path; carriers with no partner relationship were cancelled at wind-down; the two SaaS companies were potential competitors for the same shippers, so they were cancelled, one after legal review.

Q3. What was your cadence and how did you communicate?

The decision went through the RAPID steps — recommend, input, agree, decide — then the Inform step listed who needed to know, and the Commitments step had every impacted party confirm, verbally in the meeting or in writing by email. Day to day, shadow-account bugs were read in the daily stand-up and wave readiness in the weekly program review. VERIFY the customer-facing notice timing — safe sentence: "Customers were told from the dated list; I won't quote a notice period I can't point to."

Q4. Was Crux actually shut down on time?

VERIFY the final shutdown date. Safe sentence: "The plan targeted end of 2022, and the record shows the cancels dated through October 2022 and every remaining customer on a path; I'd rather not state a final switch-off date I can't show you."

Pointers, bridges and VERIFY

WHERE THE OTHER ROCKY MATERIAL LIVES (NOT REWRITTEN HERE)

IF HE ASKS FOR…	GO TO
The UDC dual-inventory program end to end — discovery, arch council, cutover, hypercare	*amazon-nacf-udc-canada-story-pack-star-kimi-k3*, story B1
US-managed bulk ship to Canada (plan at discovery exit; outcome VERIFY)	Same pack, story B2
A failure on my own slide (FSD sign-off planned Jul 26, signed Aug 14)	Same pack, story B5
The Locus slip told as a failure (vendor dependency carried as a task)	*amazon-nacf-panel-3-goforth-bar-raiser-bank-star-kimi-k3*, F4
More stories (R1–R9), failures F1–F4, the 32-answer LP bank	The Bar Raiser bank

HOW THE THREE STORIES MAP TO HIS ASK

HIS THEME	P2 RP → JDA	P3 LOCUS SLC	P4 CRUX
Program cadence	Weekly RAID; phase-gate reviews; mock scorecards	Track status page + Jira; weekly two-block program status	RAPID steps; daily shadow-account stand-up
Cost vs speed	Held discovery; paid a 72-hour freeze for reversibility	Re-slot vs compress UAT; throttle 30% to carts	Segment it vs one shutdown date vs full parity
Large-scale deployment	Two DCs, hundreds of RF devices	31 access points, two closets, fiber ring, bots	79 customers, 294,581 containers a year
Stakeholders	Sponsor, Finance, DC Ops	Vendor, wiring contractor, IT, DC Ops	Executives, transition-plan owners, partner team, legal

VERIFY ITEMS (SAFE SENTENCE FOR EACH)

ITEM	SAFE SENTENCE
P4 — my named role in the Crux RAPID (not listed in its RAPID table)	“The decision rights sat with the product leads and two executives; my part was the program — the destination-and-date plan, the shadow accounts and the wave gates.”
P4 — final Crux switch-off date	“The target was end of 2022; the record shows dated cancels through October 2022 and every remaining customer on a path.”
P4 — customer notice period	“Customers were told from the dated list; I won’t quote a notice period I can’t point to.”
P3 — vendor-side root cause of the three-week retail-testing slip	“The integration items open then were the API style, customer-owner configuration and tote mapping; I won’t pin the slip on one of them.”

Number rules for this part. Say “hundreds of RF devices” (never a ratio of two counts). The $20M is a pipeline of four projects, not savings; “about $2.5M a month” is my division, never banked. 343 timed tasks is the UDC cutover, not RP → JDA. The +15% is DC Ops’ measurement for the whole UDC program. The $185,892 is the documented legacy ARR base, not money lost. All four RAPID uploads (a66c, dd61, c0ee, e582) carry identical text; e582 was used.

INTERVIEW-PREP STORY PACK · COMPANION TO PACKETS 3, 4 AND 5 · BUILT FROM THE TWO DOCUMENTS UPLOADED THU OCT 29

Amazon NACF Supply Chain loop — UDC Dual Inventory & US-Managed Bulk Ship to Canada: STAR story pack

Amazon — Senior Supply Chain Manager, NACF Supply Chain (L6) · Rajesh Rishiyur Chandrasekaran

Friday, October 30, 2026 — all three interviews

10:00 Rocky Goforth (Amazon Infrastructure; Bar Raiser) · 11:00 James Cabreros (placement / configuration architecture; schedule listed Zhaowen Lan) · 12:00 Venkata Josyula (Principal PM, FBA)

Keystone source: “UDC Dual Inventory with New WMS (BlueYonder 2023.1 Upgrade) — Arch Council Review”, July 31, 2024 (17 slides)

SECOND SOURCE: “US MANAGED BULK SHIP TO CANADA — SOLUTION APPROACH PROCESS FLOW – SPIKE”, JUNE 12, 2023 (1 PAGE) WITH ITS COMPANION “DISCOVERY RESULTS” DECK, JUNE 14/16, 2023 (25 SLIDES). THIS PACK CREATES NEW FILES ONLY; IT DOES NOT CHANGE ANY OTHER PACKET.

What this pack is for. Rocky asked for exactly this program: “UDC dual inventory through discovery, arch council, till hypercare — frameworks to bring consensus, ambiguity, stakeholder management, communication, cutover, hypercare support end to end.” The Architecture Council sign-off deck is the primary record of that program and the in-flight packets may have been built without it. Section A digests both new documents page by page and reconciles them against the master, GFiber v8, Apple v11 and the issues log. Section B tells the material five ways — one angle per interviewer, so the three of them cannot compare notes and hear the same story twice. Section C is the alignment patch list for the other packets (also at /tmp/udc-canada-alignment-patchlist.md). Section D is the source trace, the VERIFY list and questions to ask.

Integrity rules on every page: every number carries a basis label — **record** (Apple v11 / resume), **record-from-docs** (a page of the two new decks or the issues log), **user anchor** (GFiber v8 only — confirm before saying the exact figure), **modeled**, **illustrative**. The Canada program's *outcome* is in none of the sources — its results are spoken as “the plan at discovery exit” until the VERIFY line is confirmed. Nothing here is a design case; both programs are lived record.

Already told on Thu Oct 29: S/4HANA / ISM, Flexport estimation, Shipment Visibility, safety stock, the 200-lane lead-time program. None appears here except as a one-line bridge.

Sources: /tmp/sources/UDC_Dual_Inventory_with_New_WMS-_Arch_Council_Sign_off_4d73.txt + page images (pp. 5–8, 10, 13–17 read as images); US_Managed_Bulk_Ship_to_Canada_cef9 (spike, image); US_Managed_Bulk_ship_to_Canada_Discovery_Results_aac6; Apple PM III workbook v11 chapters C1–C4, D1–D2, G2; GFiber MASTER v8 S2/S5 (pp. 46–50); master packet S2/S5/S18; NUMBERS-RECON.md CANON v2 rows 43–62; UDC_Consolidated_Issues_Log (836 rows, pandas counts per recon); UDC_LOCUS_Retail_Track (two identical-text copies); Locus Wiring Install SOW v1.4 (Nov 19, 2024); resume.

Contents

A. Source digest

A1. Document 1 — the Architecture Council sign-off deck (July 31, 2024), page by page

A2. What “dual inventory” precisely means here

A3. Document 2 — US Managed Bulk Ship to Canada: the spike (June 12, 2023) and the discovery-results deck (June 14/16, 2023)

A4. Conflicts table — new documents vs master / GFiber v8 / Apple v11 / earlier docs, with resolution

B. Stories (STAR; one angle per interviewer)

B1 · ROCKY · UDC Dual Inventory with the new WMS — discovery → council sign-off → build/test → cutover → hypercare (program / SDLC lens)

B2 · ROCKY · US-Managed Bulk Ship to Canada — discovery → design → launch plan (cross-border program lens)

B3 · JAMES · the same material as PROCESS design — connectivity, node enablement, capacity signalling, escape routing, configuration governance

B4 · VENKATA · the same material as a PRODUCT / customer story — problem, prioritisation, what we did not build, metrics, adoption

B5 · the date I put on the council slide and missed (FAILURE, full STAR) · B6 · the retail E2E that moved from January 15 to January 30 (near-miss / reversed plan, full STAR)

Who hears which variant

C. Alignment patch list for the other packets

D. Trace, verify, ask

D1. Source trace · D2. VERIFY list with safe sentences · D3. Questions to ask (two per interviewer)

A1. Document 1 — “UDC Dual Inventory with New WMS (BlueYonder 2023.1 Upgrade) — Arch Council Review”, July 31, 2024

> **What it is:** the 17-slide Architecture Council sign-off deck for the UDC (Utah Distribution Center) dual-inventory conversion coupled with the Blue Yonder WMS 8.2 → 2023.1 upgrade. Footer on every slide: “July 31, 2024 | Sephora Confidential”. Diagram frames carry the “Sephora Enterprise Architecture” title block (Version 1.0 / Version 1 / Version X). File title: “UDC Dual Inventory with New WMS- Arch Council Sign off.pptx”.
> **Author / presenter:** the deck names no author. Apple v11 C4 (p. 26–28) is the candidate's own record that he owned the council case; Apple C4's source line cites this exact file. **Audience:** the Architecture Council (“Arch Council Review”, p. 1).
> **Date position:** the timeline (p. 10) puts “Today” at the end of July 2024, after “Discovery Kick Off Mar 29”, “Discovery Results Jul 18” and “FSD Sign off Jul 26”, and before the E2E chain and the two go-lives.

PAGE	SLIDE	WHAT IT SAYS (EVERY NUMBER, VERBATIM WHERE IT MATTERS)
1	Title	“UDC Dual Inventory with New WMS (BlueYonder 2023.1 Upgrade) · July 31st, 2024 · Arch Council Review”.
2	Agenda	Project objectives and goals · scope & goals · current-state architecture · future-state architecture · E2E high-level architecture design · systems impacted · project timelines · open questions.
3	Objectives and goals	**Background:** UDC operates as two separate channels (Dotcom and Retail), which requires multiple systemic Warehouse IDs even though inventory exists within a single physical building; inventory is also kept in physically separate storage locations per channel. **Benefits of dual inventory (5):** optimise inventory planning and ordering; receive POs as a single warehouse rather than two; improve storage-space utilisation by mixing both channels in storage locations; reduce the need to systemically transfer inventory between UDC Dotcom and UDC Retail; “sets the stage for upcoming Midwest DC”. **Benefits of BY WMS 2023.1 (4):** portal/web-based application instead of thick client (easier user rollouts); updated technology for server clustering and new integration capabilities; supports Android mobile devices; UI development via React.
4	Scope	**In scope:** UDC converted/merged into a single dual-inventory location with RETAIL and DOTCOM merged and operationally managed as ONE DC (“OMNI facility”); existing UDC Dotcom locations 801/800 decommissioned and replaced with a new UDC Dotcom selling location 900 mapped to the existing DC inventory location 901, converting 901 into a comingle / dual-inventory DC; from the digital standpoint 801/800 replaced with 901/900 “with no conversion done for historical transactions”; “all existing Comingle Reserve Management functions that exist for Canada will be 100% replicated to US”. **Out of scope:** changes to Comingle Reserve Module calculations; decommissioning of functionalities from MCS (handled by the Global ERP project).
5	Current-state architecture (diagram)	“UDC – JDA 8.2 WMS Current State Architecture, Version 1.0”. Azure East: JDA WMS 8.2 app cluster — three WMS front ends with Locus / Retail / Dotcom integration, backend jobs, EMS & archive, standby, front-end load balancer; JDA Shared Services cluster (2 nodes); Proship cluster (4 apps + LB); ESB (Kafka); Cloud Engineering SFTP and Exchange SMTP. Equinix East: three Oracle ODA 19c databases (WMS, shared services, Proship). UDC server room: Locus app; floor clients Cubiscan, RF handhelds, PCs, label printers.
6	Future-state architecture (diagram)	“UDC – BY WMS Future State Architecture, Version 1.0”. New (green): BY WMS 2023 app cluster — three WMS front ends each with a Portal, Locus / Retail / Dotcom integration, backend jobs, EMS & archive, standby, front-end LB; the WMS database moves to Oracle OCI 19c at “OCI East”; floor clients gain Android mobile and browser. Unchanged (white): JDA Shared Services and Proship clusters and their Oracle ODA databases at Equinix East; ESB/Kafka; SFTP/SMTP; Locus app in the UDC server room.

PAGE	SLIDE	WHAT IT SAYS (EVERY NUMBER, VERBATIM WHERE IT MATTERS)
7	E2E high-level design — front end (diagram)	“UDC WMS 2023 Frontend Architecture, Version 1”. Source: OKTA (SSO), Portal DB, WMS DB, Splunk. Middleware: three front-end servers, each running Portal Server, Mobile Adaptor, MTF Server, Moca Server; three load balancers — HTTPS Portal LB, HTTPS Mobile LB, MTF LB. Targets: browser, Android mobile, RF gun.
8	E2E high-level design — React extensions (diagram)	“UDC WMS 2023 React Extensions, Version X”. Frontend server: Moca Server, Portal Server, React App behind a Reverse Proxy; the browser renders a BY page and a React page side by side, both calling the API. WMS DB and Portal DB as sources.
9	Systems impacted (table)	Seven system families, one change line each: (1) WMS, JDA Shared Services, Proship, Locus, TMS, New Store-ODS — BY WMS 2023.1 upgrade at UDC; JDA SS / Proship / Locus testing with the new WMS; TMS wh_id changes for inbound POs from W801 to W901. (2) MCS — Bowser, FRAME, MERLIN — location setup, PO creation and inbound; supporting WMS conversion and outbound (B2B Retail and B2C Dotcom). (3) ESB — new Kafka topics for UDC dual inventory and AIS integration. (4) Digital — OMS, Yantriks, Narvar, C3, RPS, BI/Loyalty, CTR, CT, EPS — OMS/Yantriks set up new source DC W901; Dotcom/Finance/EDW changes for the location change. (5) Finance — SAP, Aptos, Vertex, Anaplan. (6) EDW & Reporting. (7) HR — Dayforce. Counted: about two dozen individually named systems in seven families.
10	Project timeline — upstream systems (Gantt)	“UDC Dual Inventory Upstream Systems PO Creation Go Live”. Milestones: Discovery Kick Off **Mar 29** · Discovery Results **Jul 18** · FSD Sign off **Jul 26** · “Today” (end July) · Inbound E2E testing completion (BY upgrade + UDC upstream) **Nov 22** · Dotcom outbound E2E completion **Dec 20** · Retail outbound E2E completion **Jan 15** · UDC Dual Inventory PO Creation Go Live **Jan 15, 2025** · UDC Dual Inventory & BY Upgrade Combined Go Live **May 5, 2025**. Bar “UDC Dual Inventory Upstream Systems Go Live: Mar 28 – Jan 15”. Build & test windows: track A (location setup, PO creation, inbound) — MCS Jun 9–Aug 30, Bowser/FRAME Jul 9–Aug 30, AIM Aug 1–30, SAP Jul 9–Aug 30, MCS/Merlin Jul 9–Aug 30, MCS/FRAME Jun 9–Aug 30; track B (supporting WMS conversion and outbound) — MCS, MCS/FRAME, MCS/ESB/WMS all Aug 1–30; track C (Dotcom/Finance/EDW) — MCS Aug 1–30, Digital Jul 9–Aug 30, Finance Aug 1–30, EDW Aug 1–30. **Reading:** the upstream MCS/FRAME build was already five weeks in when the council met; the WMS-conversion and outbound tracks start the day after sign-off.
11–12	Questions / Appendix	“Questions? requirements” divider, then appendix.
13–14	System requirements (table, 44 rows)	Rows 1–21 “Location Setup, PO Creation and Inbound”: new UDC.COM selling location 900 and 901 converted to a comingle location (MCS; MCS/Frame; SAP); PO generation with Dotcom Reserve, Retail Reserve and Uncommitted for comingled 901 (Frame, MCS); DC2DC SO generation into 901; a new put-away tracker (receipt confirmation, PA put-away, negative merch reserve, OOB inventory-out-of-balance variance reporting, archival); channel split on merch reserve for on-order postings to Frame and inventory postings to Merlin; non-PRTV transfer receipt on RC; comingle reserve maintenance bulk upload extended to the US; Bowser order-opt feed to treat “Dotcom only” US SKUs the way “CA Only” SKUs are handled for Canada; AIM one-time copy of all DOTCOM assortments (including samples) from 800 to 900; Frame auto-copy of on-hand/on-order and Dotcom split % from DC-0801 to DC-0900 until 801 is decommissioned; receipt processing for reserved 901 POs before the WMS conversion. Rows 22–27 “Supporting WMS conversion and outbound”: Harmonized Code feed to the new BY WMS; decommission 801/800; conversion script to support **100% 05/01 transfer** of inventory from one location to another with LOST/FOUND included; receipt processing for 801 POs after conversion with automated inventory move 801 → 901; one-time copy of sales history and forecast from DC-0801 to DC-0900. Rows 28–44 “DOTCOM related changes”: set up new dotcom locations 900/901 replacing 800/801 in OMS, RPS, C3, Yantriks, BI/Loyalty, Services/CTR, Adaptor, DP, EDW, CT, Narvar, EPS, Aptos, Vertex, Anaplan; MCS one-time conversion to zero out 801 inventory from the Yantriks publish standpoint and a FULL inventory publish for comingle 901/900 to Yantriks.
15–17	WMS 2023 React (screens)	Blue Yonder 2023 portal, warehouse W901, Outbound Planner menu (Dashboard, Outbound, Waves and Picks, Inventory, Work Queue, Configuration, Send RF Message, Order Line Mass Update, Log Indirect Work, Shipment Mass Update, RF Display, Plannable Order Details). A custom React “Gift Card” extension: assign 25 / 10 / 5 cards, gift cards by dispatch date (8 total: 2024-06-08 1 card, 2024-09-01 7 cards), serial-pin scan, batch progress. Evidence the React path on p. 3 was actually built.

Decisions, options, constraints, risks, sign-off criteria, owners, timeline — as the deck carries them

ITEM	IN THE DECK (PAGE)	NOT IN THE DECK — WHERE IT COMES FROM
Decision asked	The title is the ask: sign off the future-state architecture (p. 6–8), the location/inventory model (p. 4), the systems-impacted scope (p. 9) and the dated timeline with two go-lives (p. 10). The out-of-scope lines (p. 4) are presented as part of the ask.	Apple C4 (p. 28) frames it as three decisions — architecture, staged timeline, peak-freeze boundary. The peak freeze is not on any slide (see A4 #8).
Options considered	The deck shows the chosen option only; there is no alternatives slide. The choices are visible by contrast: current vs future state (p. 5 vs 6); replicate Canada's reserve functions 100% vs change them (p. 4); new 900 with no historical conversion vs converting 801/800 history (p. 4); staged PO-creation go-live then combined go-live (p. 10).	The rejected options (single go-live; a US-tuned reserve engine; converting history) are the candidate's record in GFiber v8 pp. 48–49 and Apple C4 — user anchor / record.
Constraints	Single physical building, two systemic warehouses (p. 3); MCS decommission belongs to the Global ERP project (p. 4); reserve calculations frozen (p. 4); the WMS upgrade and the inventory model share one critical path (p. 9–10); upstream build already open (p. 10).	Oct–Dec peak freeze and "zero customer-facing incidents" — Apple C1 (record).
Risks	Implied by the requirement rows: two live truths during the interim (rows 19, 21: Frame auto-copies 801 → 900 until decommission); the irreversible publish (rows 24, 35, 36); every digital/finance system re-pointed to 900/901 (rows 28–44).	Named RAID top three (interim drift; Locus ramp without a stop condition; peak collision) — GFiber v8 p. 48 (user anchor).
Sign-off criteria	Not stated as a checklist. The "Questions? requirements" slide (p. 11) and the 44-row appendix are what the council was asked to accept.	"LOE from every impacted team by 7/2; every row pre-read" — Apple C4 (record).
Owners / RACI	System → change mapping on p. 9 and a "System(s) Impacted" column on every one of the 44 rows (p. 13–14). No person names.	~80 named participants across ~15 functions are on the separate Discovery Results deck (Aug 14, 2024) cited by Apple C4 — not uploaded; record via Apple.
Timeline	p. 10 in full (above).	Cutover plan 343 tasks May 1 → Jul 1, 2025; hypercare — Apple C2 / GFiber v8.

A2. What "dual inventory" precisely means here

DEFINITION, GROUNDED IN P. 3–4 AND ROWS 1–6, 19–21, 24, 35–36

One physical building, one inventory location, two selling identities, channel reserves. Before: UDC ran as two systemic warehouses — Dotcom (inventory location 801, selling location 800) and Retail (901) — with physically separate storage and systemic transfers between them. After: a single DC inventory location **901** holds both channels' stock comingled in shared storage locations; Retail keeps 901 as its selling identity and Dotcom gets a new selling location **900 mapped onto 901**; purchase orders are generated and received once against 901 with three reserve buckets — Dotcom Reserve, Retail Reserve, Uncommitted — maintained by the comingle reserve logic replicated 100% from Canada. 801/800 are decommissioned with no conversion of historical transactions; during the interim, Frame auto-copies on-hand, on-order and the Dotcom split % from 801 to 900 until decommission, and the May conversion script moves 100% of inventory on 05/01 with lost/found included, zeroes 801 in the Yantriks publish and republishes 901/900 in full.

So "dual" means dual-channel, not duplicate. It is one pool with a channel partition, not two copies of inventory. The sentence to say: "Two channels, one pool: one inventory location, two selling identities, and the reserve logic decides who may promise what."

A3. Document 2 — US Managed Bulk Ship to Canada

2a. “Solution Approach Process Flow – Spike”, June 12, 2023 (1 page; Sephora Confidential). A process-flow diagram of the MCS → FRAME brand-transition design, each box tagged with its requirement ID: **MCS Brand Transition** (7.1 CA-managed brand change) → **FRAME feed** → **SKU** (Newness and Initial-PO flags, U_XDOCK_FLG — 7.2.1/7.2.2) fanning to SKUDEMANDPARAM / SKUPLANNINGPARAM / SKUSAFETYSTOCKPARAM / SKUDEPLOYMENTPARAM (7.2.3–7.2.6); **NETWORK** → TRANSLEADTIME (7.3.1); **SOURCING** → LOADDUR/UNLOADDUR, ORDERGROUP, MAJOR/MINORSHIPQTY (7.4.1–7.4.3); **Planner Code Setup** (7.5 planner-code adjustment in FRAME); **PO Outputs** → Search Adjustments (6.11.1 US searches, 6.11.2 CA searches) → Newness / Core / Promo Prebuild (6.12.1.1 promo pre-build purchase orders) → **XDOCKPO** (6.8 XDOCK PO creation for newness and replenishment). No people, no volumes — it is the design artefact behind the discovery deck's “System Changes” slide.

2b. “US Managed Bulk Ship to Canada — Discovery Results”, cover June 14, 2023, slide footers June 16, 2023 (25 slides). Agenda: discovery timeline · objectives and goals · scope · solution overview · business-process impacts · system changes · brand transition plan · project timeline · next steps.

PAGE*	SLIDE	CONTENT (EVERY NUMBER)
4	Why	“Canada is growing at a very high pace.” Some brands are not yet shipped directly to Canada (US Managed): “around 13% volume” is shipped from US DCs to Canada stores. With US retail growth and Canada growth, “even with a new Retail warehouse addition this is not sustainable.” Long-term goal: transition all brands to Canada-managed so they ship directly — “at least another 2 years”. The plan for the current year: purchase this inventory as XDOCK purchase orders to the Canada DC for newness and replenishment; allocate from the Canada DC to stores; pick/pack with the other Canada-managed brands. **Goals (4):** reduce US DC workload by bulk processing instead of a pick per Canada store; transition brands in phases so Canada DCs can absorb the workload; allow manual US-DC → Canada-DC transfers for overage stock; review and identify changes to also move inventory-planning workload from US to Canada for these brands.
5	Scope	**In:** create XDOCK POs for US-managed brands for Canadian store and DOTCA need via the US DC and allow allocation to Canadian stores from the Canada comingle DC; let the business transition existing US-managed brands by department / brand / vendor. **Out:** inventory rebalancing between US and CA DCs (manual DC-to-DC transfer orders outside FRAME; no new reporting); samples stay US-managed and distributed US DC → CA stores; no new report for brand differentiation; the Sephora Collection separate US DC; Canada Capture project changes (its own FSD).
7–8	Current / future process	Current: US-managed brands purchased to the US and distributed from the US DC to Canada stores and to the Canada DC for DOTCA. Future: purchased as XDOCK PO and distributed to Canada stores from the Canada DC.

PAGE*	SLIDE	CONTENT (EVERY NUMBER)
10–12	Business-process impacts	New brand setup by the US planner: no replenishment strategy in MCS; vendor → CA DC lane in FRAME in addition to vendor → US DC; merch planner code with CA planner as US-managed; load duration for vendor → Canada DC. New SKU setup: newness order-opt for CA-RETAIL and DOTCA with the US order group and review calendar; vendor case pack for the Canada DC; newness PO review shows an additional PO for CA-RETAIL. Transition to core: core order group for CA-RETAIL; replenishment review shows POs to the CA DC. BI promotion pre-build unchanged. Canada store allocation: Canada DP manages newness and core allocation like a Canada-managed brand; auto-approval holds stay at the CA retail DC. Comingled reserve: Canada Planning manages DOTCA and retail reserves for these SKUs. FRAME stops showing US-DC outbound projections for these brands; brand projections appear against the CA DC. US DC XDOCK PO processing: no new mailbox locations (751 and 1050 already exist); current Canada XDOCK process followed. Canada DC: inducted and slotted like a CA-managed brand; overage / underage / substitution follow the current US → CA process. Transportation: current inbound vendor → US DC XDOCK process; current ODS for the Canada DC; no change to truck arrangement; US Transportation keeps setting ODS for CA-store picks for samples and brands that stay US-shipped.
14–15	System changes (6, sized)	MCS — FRAME integration: SKU integration to indicate purchasing from Canada with XDOCK; CA retail DC vendor-sourced, CA stores and DOTCA sourced from the CA retail DC — **Small**. MCS — comingled inventory allocation: do not auto-allocate all unallocated inventory to DOTCA for US-managed brands — **Small**. FRAME — PO approval by US planners: US order-review searches include, CA searches exclude, US-managed vendor → Canada DC orders — **Small**. FRAME — PO review in USD — **Small**. MCS — PO creation: XDOCK PO for newness with retail reserve in addition to DOTCA reserve; XDOCK PO for core when flagged — **Small**. FRAME — brand transition scripts: set newness and initial-PO-created flags for CA retail and CA retail virtual DC SKUs so allocation and purchasing are unaffected at cutover — **Medium**.
16	Transition plan (7 action points)	1 Estimate volume: initial transfer = **10 WOS, about 2.5M units**. 2 Storage: “there is no space constraint”. 3 Brands: **Pilot = 20 OMNI brands (smaller volume); Wave 1 = 40; Wave 2 = 39**; remaining brands assessed for a plan starting Jan 2024. 4 Process/training: existing US → CA-managed transition material revised — in progress. 5 Front-load: QH added to DOTCA to create replenishment demand into the US DCs; inventory transferred to CA before the MCS sourcing change — in progress. 6 Finalise: flip MCS to set Canada DCs as sourcing DCs for CA-Retail and DOTCA. 7 IT supports the pilot-brand transition.
17	Pilot brands (20)	Brand #, name, estimated transfer units, SKU count — summing to **217,416 units and 671 SKUs** (computed). Largest: Sephora Favorites Kits 85,693 units / 15 SKUs (39% of pilot units); smallest: Floral Street 884 units / 38 SKUs. Others: Fable and Mane 22,367; Westman Atelier 19,197; Glamnetic 16,361; Lys Beauty 11,634; Freck 9,992; Phlur 6,058; Skylar 5,659; Shani Darden 5,516; Blinc 5,424; Maison Louis Marie 5,040; Adwoa 4,834; Commodity 4,112; Cinema Secrets 3,953; Ellis Brooklyn 3,654; Augustinus Bader 2,599; Rosie Jane 1,750; Makeup Eraser 1,603; Forvr Mood 1,086.
18	Transition schedule (Gantt)	Weekly columns 11-Jun through 3-Sep; rows Pilot, Wave 1, Wave 2; each brand runs four steps — Apply QH → Transfer Inventory → Change Sourcing → Release X-Dock PO. Exact per-wave week spans are not recoverable from the text.
19	Brand transition execution	Business supplies five data sets per cutover (dept/brand/vendor list; planner-code setup by dept/class/brand; load/unload duration; case pack; network lead time). IT executes before the FRAME nightly batch: delete the replenishment strategy; create CA Retail and CA Virtual DC SKUs in FRAME with initial-PO, newness flag and order groups from the US DC; update XDOCK flags; set planner codes; upload durations, case packs and lead times.
20	Project timeline	**Discovery 4/17/23 – 6/23/23 · Build & test (target) 6/28/23 – 8/1/23, Sprint 2023.15 · Go-live: brand cutover start 8/3**. Markers: discovery completion; “We are here”; FSD sign-off + build-plan completion.
21	Next steps	FSD sign-off by business teams by **6/23** to move to build; develop the changes; finalise brand transition plans.

PAGE*	SLIDE	CONTENT (EVERY NUMBER)
22–23	Approvers / team	**17 approvers** (Yvonne Kwan … Melissa Parrino). **Steering committee:** Mike Racer, Rosie Pouzar, Kalyan Adavi. Core IT: IT owner Harshitha Koka; engineering owner Navin Gupta; tech architect Sudheer Kunduru; BA Mike Sullivan; FRAME lead Amar Lad; **Project Manager — Rajesh Chandrasekaran**. Business partners: business owner Yvonne Kwan; SC Strategy (Scott Walters, Joshua Behm); CA Planning (Sandra Gurizzan); CA Operations (Rose Silva); US Planning (Anastasia Esparza); US Distribution (Darlene Singson); CA Logistics (Melissa Schaus, Dave Ashwood); US DC Planning & Engineering (Joe Zarzycki); US Transportation (Matt Arnold, Melissa Parrino); UDC (Matt Cannon, Chris Burrell, Aaron Bender); MDC (Charles Schreyer, Dave Holder). QE: Deepika Paruchuri, Kalyani Swabhanam. Logistics: Cody Mathews. Blue Yonder: Gilberto Silva (solution architect), Mitalee C (technical architect).
24–25	Discovery deliverables	Requirements and epic drafts; determine and validate scope; high-level timeline validation; rollout/transition plan — these “dictate build-plan completion”. Status: P0 walkthrough & FSD sign-off — in progress; go-live target-date alignment — in progress.

*Page = slide number printed on the deck; the text extraction's [p#] markers differ (the PDF is an Office export). Cite the slide number.

A4. Conflicts table — new documents vs master / GFiber v8 / Apple v11 / earlier docs

#	CLAIM	NEW DOCUMENT	OTHER SOURCE	RESOLUTION — WHAT TO SAY
1	FSD sign-off date	Council deck p. 10: “FSD Sign off Jul 26” (a plan marker, five days before the meeting).	Apple C4 p. 28 and master S2/S5: “FSD + discovery results 8/14”. Recon S5.01 MATCH on 8/14.	**Planned 7/26, landed 8/14** (about three weeks later). Say “the council deck targeted late July; the FSD was signed mid-August.” This is the B5 failure story — own it, do not hide it.
2	Discovery-results date	p. 10: “Discovery Results Jul 18”.	Apple C4 cites the Discovery Results deck as “25 slides, Aug 14 2024”.	Same slip as #1. Say “discovery results and FSD closed together in mid-August.”
3	Retail outbound E2E completion	p. 10: Jan 15 (2025).	Apple C1 p. 22 / master: Retail E2E 1/30; Apple C3 p. 26: “RTL E2E completion Jan 31”; Apple C2: Locus retail testing slipped three weeks.	The deck is the July plan; the slip is the record. Say “planned for January 15; after the Locus retail re-slot it completed at the end of January.” The two documents corroborate each other (B6).
4	Combined go-live date	p. 10: “May 5, 2025”.	Apple C1: “combined go-live May 2025”; cutover plan dated 1 May → 1 Jul 2025 (Apple C2); requirement row 24: 100% inventory transfer on 05/01.	Consistent. Say “the first week of May 2025 — inventory moved on May 1 under the conversion script, combined go-live May 5.” Label the day record-from-docs.
5	PO-creation go-live	p. 10: Jan 15, 2025.	Apple C1: January 2025; GFiber v8 p. 47: “interim Jan 15 → May 1”.	Consistent — say “January 15.”
6	How many systems	p. 9: seven families, about two dozen named systems; p. 13–14: 44 requirement rows across 23 named systems.	Apple C1/C4: “about a dozen impacted systems”; GFiber/master: “a dozen core, 20+ touched”; recon S2.10 told packets to say “about a dozen” and treat 20+ as unverified.	The primary document now supports both readings: **“seven system families — about a dozen domains — and about two dozen individually named systems on the council's impact table.”** Source docs outrank Apple under the recon's precedence; keep “about a dozen” as the domain count so earlier packets are not contradicted.
7	When the council met	Deck is dated July 31, 2024 and titled “Arch Council Review / Sign off”.	Apple C1: “architecture council May 15 — a challenge gate”; Apple C4 chain lists both 5/15 and “sign-off pack 7/31”.	Two touchpoints: **May 15 challenge review, July 31 sign-off**. Never say “the council met once.”
8	Peak-freeze boundary “ratified at council”	No slide or Gantt band shows an Oct–Dec freeze.	Apple C1/C4, GFiber: third decision asked = peak-freeze boundary.	The freeze is record (Apple C1) as a program rule; its ratification *at the council* is user anchor. Safe: “we held a hard Oct–Dec peak freeze; the council pack carried a chain that respected it.” Do not say “slide X shows the freeze.”
9	When build started	p. 10: MCS and MCS/FRAME build & test Jun 9–Aug 30; Bowser/FRAME, SAP, Merlin from Jul 9; everything else Aug 1–30.	GFiber v8 p. 47: “Build & Test (Aug → Jan/Apr)”; Apple C1: “spec freeze in August”.	New fact: **upstream merchandising build ran at risk from June 9, before sign-off**; WMS-conversion, outbound, finance and EDW tracks opened Aug 1. Say it as the deliberate trade-off it was (B1).
10	Reserve buckets	Rows 4–6: Dotcom Reserve, Retail Reserve, Uncommitted.	GFiber v8 / master S2 math: “nine reserve types, strict priority”.	Say the deck's three buckets. “Nine” is user anchor — only if asked and confirmed.

#	CLAIM	NEW DOCUMENT	OTHER SOURCE	RESOLUTION — WHAT TO SAY
11	Program length	Kickoff Mar 29, 2024 → combined go-live May 5, 2025 = about 13 months; → hypercare close ~Jul 1, 2025 = about 15 months.	Apple C1 “fifteen months”; C2 “fourteen months”; recon: say “about fifteen months”.	Say “**about fifteen months, discovery through hypercare exit**” — true on the deck's own dates plus the dated cutover window.
12	Canada reserve functions	p. 4: “100% replicated to US”.	GFiber/master: “replicated 100% from Canada”.	MATCH.
13	Midwest DC	p. 3: “Sets the stage for upcoming Midwest DC”.	GFiber v8 p. 47: hypercare template handed to the Midwest DC.	MATCH — a stated objective in July 2024 and a hand-off in 2025.
14	Hypercare exit bar for UDC	Nothing on hypercare in the deck.	GFiber v8 pp. 47–50: blockers/day < 2 sustained, exit week 3 of 4; Apple D1 states the same bar for the JDA program (S18).	For UDC the bar is **user anchor**; the burn-down 271 → 65 → 21 → 14 → 4 is record-from-docs (issues log). Say “the same under-two-blockers-a-day bar I had used on the JDA migration; the June spike burned down 271, 65, 21, 14, 4.”
15	Canada bulk-ship program — existence and outcome	Spike (Jun 12, 2023) + Discovery Results (Jun 14/16, 2023) name Rajesh as Project Manager and give scope, sizing, waves and dates.	Not in Apple v11, the master, GFiber v8 or the resume text.	Entirely new story (B2/B3/B4). The **plan** is record-from-docs; the **outcome** (did cutover start Aug 3, how many brands moved, workload effect) is **VERIFY**. Speak results as “the plan at discovery exit” until confirmed.
16	Canada deck date	Cover “June 14th, 2023”; footers “June 16, 2023”; spike June 12.	—	Say “mid-June 2023.”
17	“Dual inventory” wording	Deck uses “Dual Inventory”, “Comingle/Dual Inventory DC”, “OMNI facility” interchangeably.	Master/Apple use “comingle pool”, “one omni facility”.	Use A2's definition; never let “dual” sound like two inventories.
18	Locus status page	UDC_LOCUS_Retail_Track (two uploads, identical text): program YELLOW; UAT 2/28–3/15; sockets vs REST; tote-type / base-36 carton-id request; cust-owner config SEPHORA-RTL.	Apple C3: physical testing Feb–Mar 2025.	Consistent; the YELLOW status and the UAT window are record-from-docs for B6.
19	Locus network expansion	Locus Wiring Install SOW v1.4, Nov 19, 2024: Salt Lake City expansion — IDF3/IDF4 added, 31 MR46 access points added (APs 19–49), 3 fiber runs, existing rack with 2 MX85, 2 MS210, 2 R740 + 1 R640 servers.	Not in other sources.	Record-from-docs; use only in B3/B6 as the physical-readiness evidence. Do not state a dollar.

B1 · ROCKY · UDC Dual Inventory with the new WMS — discovery → Architecture Council sign-off → build/test → cutover → hypercare NEW — BUILT ON THE COUNCIL DECK

Interviewer lens: engineering/program leader — large-scale deployment, program cadence, consensus, ambiguity, stakeholder management, cutover, hypercare. No math tables.
LPs: Earn Trust · Ownership · Insist on the Highest Standards · Deliver Results. **Headline number:** zero customer-facing incidents across two go-lives (record); +15% processing efficiency, DC Ops' measurement (record).

60-SECOND PITCH

Let me walk you through the most complex deployment I've run end to end: converting a live Utah distribution center from two systemic warehouses into one omni facility while upgrading the warehouse system underneath it — Blue Yonder 8.2 to 2023.1 — with Locus robotics on the same critical path. I owned the program from discovery kickoff on March 29, 2024, through the Architecture Council sign-off on July 31, through two go-lives — purchasing and inbound on January 15, 2025, and the combined inventory flip on May 5 — and out of hypercare. The council pack touched seven system families, about two dozen named systems, in a 44-row requirement table. The consensus method was simple and expensive: discovery with every team, a level-of-effort from every owner before anyone saw a slide, a pre-wire where every owner read their own row, and then a council ask with written edges — what we were changing, and what we were not. Both go-lives landed with zero customer-facing incidents, the June hypercare spike burned down in four weeks, and DC Ops measured processing efficiency up fifteen percent afterwards.

S — Situation. Sephora, spring 2024. UDC shipped from two systemic warehouses inside one building — Dotcom on inventory location 801 with selling location 800, Retail on 901 — with physically separate storage, duplicate receiving, and systemic transfers between the two sides for no customer value (deck p. 3). Leadership wanted one omni facility, and the WMS version underneath was going to a web, Android and React front end at the same time (p. 3, p. 6–8). The Architecture Council was the challenge gate: no sign-off, no build. The ask carried two constraints I did not get to negotiate: zero customer-facing incidents, and the building's October-to-December peak untouched (Apple C1, record).

T — Task. I owned the program end to end — discovery through FSD, the council case, the staged timeline, the cutover runbook and the hypercare exit — without owning any of the systems. About sixty stakeholders sat on the steering path; the discovery deck later listed about eighty names across fifteen functions (Apple C4, record).

A — Action. I ran it as five gated phases — entry bar, what I delivered, exit bar — and the council was the second gate's exit.

- **1. Discovery (Mar 29 → early July 2024).** *Entry:* a sponsor charter — one omni facility, zero customer-facing incidents. *Delivered:* one discovery session per impacted team, March through July; a profile of both books (SKU overlap, order profiles) so comingling was sized, not assumed; a systems-impacted table with one row per system and one change per row; a level-of-effort from every owner, the last landing July 2 (Apple C4, record). *Exit:* every row has a named owner and an LOE; open questions are dated.
- **2. Plan & design → Architecture Council (May 15 challenge review; July 31 sign-off; FSD signed mid-August).** *Entry:* the LOE-backed table. *Delivered:* the sign-off pack — current state versus future state (p. 5–6), the front-end and React architecture (p. 7–8), the location model 801/800 → 900 mapped onto 901 with no historical conversion (p. 4), the seven-family systems-impacted table (p. 9), the dated plan with two go-lives (p. 10), and the 44-row requirement appendix (p. 13–14). The decision rows I asked the council to sign: (1) the future-state architecture — BY 2023.1 on a new OCI database, portal/Android/React front end, new Kafka topics; (2) the location and reserve model — one pool, two selling identities, Canada's comingle reserve functions replicated 100%; (3) the staged timeline — PO-creation go-live January 15, combined May 5, with the E2E chain Nov 22 / Dec 20 / Jan 15 as public

dates; and (4) the fence — reserve calculations untouched, MCS decommission to the Global ERP project (p. 4). *Exit:* sign-off July 31; FSD signed August 14 — three weeks after the July 26 date I had printed on the slide (B5).

- **3. Build & test (upstream MCS/FRAME from Jun 9 at risk; all other tracks Aug 1 → Jan 2025).** *Entry:* signed architecture, FSD, LOE per track. *Delivered:* about thirty build tracks under one issues log — 836 rows over the program, one grammar: type, severity, operation, owner (Apple C2, record); the dated E2E chain as the spine every track read — inbound Nov 22, dotcom Dec 20, retail planned Jan 15 and landed Jan 30 after the Locus retail re-slot; the Locus gate — 98% pick-accurate throughput published before a bot moved, with the manual-cart throttle built as a dial (Apple C3, record). *Exit:* E2E green per flow; Blocker + Critical open = 0 at each go/no-go.
- **4. Cutover (Jan 15; May 1 → Jul 1, 2025).** *Entry:* go/no-go read off counted rows, not confidence. *Delivered:* January moved purchasing and inbound only — the floor untouched — then a four-month interim where Frame auto-copied on-hand, on-order and the dotcom split from 801 to 900 (rows 19, 21) and daily reconciliation watched for drift; May's runbook was 343 tasks, about 815 task-hours, each with owner, duration and predecessor (Apple C2, record); the one irreversible instant was the conversion script's 100% inventory move on May 1 with lost/found, zeroing 801 in the Yantriks publish and republishing 901/900 in full (rows 24, 35, 36). Rollback was per interface behind two armed triggers — sync below 99% for four consecutive hours, or order-flow p95 above twice budget for an hour (resume / GFiber; user anchor on the exact thresholds). *Exit:* invariants held — inventory conserved across the move, no SKU sellable on 800 and 900 at once; rollback never fired.
- **5. Hypercare (May → late June 2025).** *Entry:* combined go-live May 5. *Delivered:* a daily burn-down read — the June spike of 271 log rows decayed 65, 21, 14, 4 in the following months (issues log, record-from-docs); the Locus weekly gate read until full volume in week three; a written hypercare exit memo, template handed to the Midwest DC the deck had named as the next building (p. 3). *Exit:* blockers per day under two, sustained — the same bar I had used on the JDA migration — exited in week three of four (user anchor).

R — Result. Both go-lives landed on the staged dates with zero customer-facing incidents (record). DC Ops measured processing efficiency up fifteen percent after stabilisation — their number, not my model (record). 85.4% of the 836 issues closed with the tail visible and owned; Locus held to about a tenth of the book (record). The approved architecture carried both go-lives with no mid-build boundary dispute, and the same systems-impacted table became the cutover plan's spine (Apple C4, record). **Reflection:** the interim period — two systems of record for four months — deserved a named reporting workstream from the first deck; it got one in month three.

HOW CONSENSUS WAS ACTUALLY EARNED — THE FRAMEWORK

MECHANISM	WHAT I DID	EVIDENCE
Discovery before any ask	One session per impacted team, March → July; the council reviewed counted impact, not optimism.	Apple C4 (record); deck p. 10 kickoff Mar 29.
LOE before the slide	Every system owner estimated their own row; the last LOE landed July 2.	Apple C4 (record).
Pre-wire	Every owner saw their row on p. 9 and their rows in the 44-row appendix before the meeting — no first reads in the room.	Deck p. 9, 13–14; Apple C4.
Decision rows, not status	Four signable things (architecture; location + reserve model; staged timeline; fence) presented as current-vs-future contrasts, each with its “what we are not changing”.	Deck p. 4–10.
Written edges	Out-of-scope lines printed on the scope slide; later used as change control when teams arrived with reserve-math improvements.	Deck p. 4; GFiber v8 p. 48 (user anchor on the specific refusals).
Two council touchpoints	May 15 challenge review surfaced boundary questions (this program vs Global ERP; interim reporting); July 31 pack answered them in writing.	Apple C1/C4; deck date.
Cadence after sign-off	Weekly two-block status — thirty minutes IT, thirty business — one dashboard, one risk register, no side decks; steering = DC Ops + IT + Supply Chain Strategy.	Apple C1 (record); GFiber v8 p. 49.

AMBIGUITY I HAD TO RESOLVE

- **What "dual inventory" meant** — to Digital it was a location change (801/800 → 900/901), to Finance a code change in four systems, to Planning a reserve question, to the DC one receiving dock. I wrote the definition on the scope slide (A2) and let each function find its row in the appendix.
- **Two truths for four months** — rows 19 and 21 made Frame the bridge (auto-copy 801 → 900 until decommission) so the interim had a mechanism, not a hope.
- **Build already running at sign-off** — the MCS and MCS/FRAME tracks had been building since June 9 (p. 10). I fenced the at-risk build to location setup and PO creation, the part discovery had already stabilised, and kept the WMS-conversion, outbound, finance and EDW tracks closed until August 1.

WHO I NEEDED

WHO	WHAT I NEEDED	HOW I GOT IT
Architecture Council	Sign-off on architecture, model, timeline, fence	Pre-wired rows; four decision rows; written out-of-scope; two touchpoints.
Steering (DC Ops, IT, Supply Chain Strategy)	The staged timeline and the peak freeze as decisions with prices	Presented the four-month interim cost openly; freeze as the ruling, not a negotiation.
MCS / FRAME / Merlin owners	Location setup, PO creation with three reserve buckets, put-away tracker, conversion scripts	Rows 1–27 owned by name; build windows on p. 10 they had estimated themselves.
Digital (OMS, Yantriks, Narvar, C3, RPS, …) and Finance (SAP, Aptos, Vertex, Anaplan), EDW, HR	Re-point 800/801 → 900/901 by the dotcom E2E date	One row each (rows 28–44); the dated E2E chain as the shared deadline.
WMS team + Blue Yonder	2023.1 on OCI, portal/Android/React front end	Current-vs-future diagrams signed by Enterprise Architecture.
Locus	A measurable ramp with a stop condition	98% gate published before arrival; throttle as a dial; three-day workshop Jul 29–Aug 2, 2024.

TRADE-OFF I MADE. Options: (a) one big-bang go-live with WMS and inventory model together; (b) staged — purchasing and inbound in January, inventory flip in May; (c) wait for sign-off before any build vs start the upstream MCS tracks in June at risk. I chose (b) and started (c) at risk but fenced. What it cost: four months of two systems of record with a Frame bridge and daily reconciliation, and five weeks of merchandising build exposed to a council "no" — which I limited to the rows discovery had already stabilised. What I rejected: the single date the business wanted (two defect classes in one week) and a US-tuned reserve engine (a second defect class in the same release). **Failure / learning line:** I printed July 26 for the FSD on the council slide and signed it August 14 — see B5.

LP proof lines. Earn Trust — every owner read their row before the room did; the fence was written where they could hold me to it. **Ownership** — I owned the case for systems I did not own, and the slip on the FSD date was mine to say out loud. **Insist on the Highest Standards** — go/no-go read Blocker + Critical = 0 and a published 98% robotics gate, never percent-complete. **Deliver Results** — two go-lives on the staged dates, zero customer-facing incidents, +15% measured by the people who run the building.

SAFE-SAY. Most attackable number: "About two dozen named systems in seven families on the council's impact table — forty-four requirement rows; I'll call it about a dozen domains if you want the round number." Source question: "The July 31, 2024 Architecture Council sign-off deck and the program's 836-row issues log; the fifteen percent is DC Operations' own measurement, not mine."

20-SECOND VERSION

I took a live Utah DC from two systemic warehouses to one omni facility while upgrading the WMS under it. Discovery with every team, an LOE from every owner, a pre-wired Architecture Council on July 31, 2024 that signed four things including what we would not change, then two staged go-lives — January 15 and May 5, 2025 — a 343-task runbook with rollback armed, and a hypercare exit on a number. Zero customer-facing incidents; DC Ops measured processing efficiency up fifteen percent.

PROBING Q&A

What did the council actually push back on, and what changed because of it?

Boundaries, which is what a good council is for: which changes belonged to this program versus the Global ERP program — answered by writing “MCS decommission is out of scope” on the scope slide; whether reserve calculations stayed frozen — they did, by explicit out-of-scope; and how the interim would report while two systems of record ran — answered by the Frame auto-copy rows and daily reconciliation, and honestly answered late. Every pushback became a written line in the pack, so the approval had edges (Apple C4, record; deck p. 4).

Your timeline shows build running in June — before the council signed. Isn't that building on an unapproved design?

Yes, and I chose it. The upstream merchandising tracks — location setup and PO creation — had been through discovery with their owners and would be needed in any variant of the design; the WMS-conversion, outbound, finance and EDW tracks stayed closed until August 1, the day after sign-off. The exposure was five weeks of fenced build; the alternative was a January go-live that could not hold. I told the council that on the timeline slide rather than hiding the bars (deck p. 10).

What was irreversible, and how would you have rolled back?

One instant: the May 1 conversion — 100% of inventory moved 801 → 901 with lost/found, 801 zeroed in the Yantriks publish, 901/900 republished in full. Everything before it was reversible per interface; everything after it was forward-fix. Triggers were armed — sync below 99% for four consecutive hours or order-flow p95 above twice budget for an hour — behind per-interface rollback, and the go/no-go required Blocker + Critical at zero and the invariants proven on the dry runs. They never fired. (Rows 24, 35, 36 record-from-docs; thresholds user anchor.)

How did you know hypercare was over?

Off counted rows: blockers per day under two, sustained, and the post-go-live spike decaying — 271 rows in June, then 65, 21, 14, 4. We exited in week three of a planned four. A calendar exit declares victory over open defects; a numeric one earns it (issues log record-from-docs; the bar user anchor).

B2 · ROCKY · US-Managed Bulk Ship to Canada — discovery → design → launch plan, as a cross-border program NEW — NOT IN ANY EARLIER PACKET

Interviewer lens: large-scale, cross-border, cost-vs-speed, launch gates, stakeholder alignment. **Role on record:** “Project Manager — Rajesh Chandrasekaran” (Discovery Results deck p. 22).
LPs: Bias for Action · Frugality · Customer Obsession · Deliver Results. **Headline numbers:** about 13% of volume to Canada stores was US-managed brands picked store-by-store in US DCs (record-from-docs p. 4); a 99-brand transition plan — pilot 20, wave 1 40, wave 2 39 — fronted by a 10-weeks-of-supply transfer of about 2.5 million units (p. 16).
Honesty line: the *plan* is record. The *outcome* — whether brand cutover started August 3, 2023 and how many brands moved — is in none of the sources: speak it as the plan until the VERIFY line in D2 is confirmed.

60-SECOND PITCH

Let me give you a cross-border program where the win was a cheap design. In 2023 Canada was growing fast, and about thirteen percent of the volume going to Canadian stores was brands Sephora still managed from the US — picked store by store in US distribution centers and trucked north. Even with a new retail warehouse coming, that did not scale, and the real fix — making every brand Canada-managed — was at least two years out. I was the project manager. We ran a ten-week discovery, April 17 to June 23, and designed the bridge: buy those brands as cross-dock purchase orders to the Canada DC, let Canada allocate and pick them with everything else, and move brands over in waves — a twenty-brand pilot, then forty, then thirty-nine. The entire system change was six items, five sized small and one medium, because we reused the cross-dock path and mailbox locations that already existed. Build and test fit in one sprint window, June 28 to August 1, and brand cutover was planned to start August 3.

S — Situation. Sephora, spring 2023. US-managed brands reached Canadian stores by store-level picks at US DCs — “around 13% volume” — and the trend of US retail growth plus Canada growth made that unsustainable even with a new retail warehouse (p. 4). The structural answer, transitioning all brands to Canada-managed, needed “at least another 2 years”. Leadership wanted the US DC workload reduced this year without breaking Canadian store replenishment.

T — Task. As project manager I had to take a discovery team across US and Canada planning, operations, logistics, transportation, two US DCs, the Canada DC, QE and Blue Yonder's architects to a signed scope, a sized design and a brand-by-brand transition plan — with seventeen named approvers and a three-person steering committee (p. 22–23) — inside ten weeks, and hand build a plan that fit one sprint.

A — Action. Five gates.

- **1. Discovery (Apr 17 → Jun 23, 2023).** *Entry:* the four goals written down — bulk processing instead of a pick per store; phased brand transition so Canada DCs could absorb the load; manual US → CA transfers for overage; a review of moving inventory-planning work to Canada (p. 4). *Delivered:* requirement and epic drafts, scope validation, timeline validation and the rollout plan — the four deliverables the deck says “dictate build-plan completion” (p. 24). *Exit:* results presented June 14, nine days ahead of the June 23 discovery close.
- **2. Design — the spike (Jun 12).** *Entry:* the current and future process agreed in one picture: purchased to the US and shipped to CA stores → purchased as XDOCK PO and distributed from the Canada DC (p. 7–8). *Delivered:* the solution-approach flow — MCS brand transition drives a FRAME feed that sets SKU flags (newness, initial PO, XDOCK) and the four SKU parameter tables, network lead time, sourcing durations and order groups, planner codes, and the PO outputs split into US and CA searches before the XDOCK PO is created (spike, requirement IDs 6.8–7.5). *Exit:* six system changes sized — five Small, one Medium (the brand-transition cutover scripts) (p. 14–15).

- **3. Scope fence and approval (Jun 14 → Jun 23).** *Entry:* the design and the out-of-scope list. *Delivered:* written exclusions — rebalancing stays manual outside FRAME, samples keep shipping from US DCs, no new reports, the Sephora Collection DC and the Canada Capture project are separate FSDs (p. 5); P0 walkthrough and FSD sign-off opened with the business asked to sign by June 23 (p. 21, 25). *Exit:* FSD sign-off and build-plan completion (p. 20).
- **4. Build & test (Jun 28 → Aug 1, Sprint 2023.15).** *Entry:* signed FSD. *Delivered (plan):* the six changes plus the seven-step IT cutover procedure run before the FRAME nightly batch, and the five data sets the business supplies per brand (p. 19). *Exit:* brand cutover start August 3 (p. 20).
- **5. Launch — brand transition by waves (from Aug 3; schedule to early September).** *Entry:* per brand, four steps in order — apply QH on DOTCA to create replenishment demand, transfer inventory to Canada before the sourcing change, flip MCS sourcing, release the cross-dock PO (p. 16, 18). *Delivered (plan):* pilot of twenty smaller-volume omni brands — about 217,000 units and 671 SKUs — with IT support; then forty, then thirty-nine; remaining brands assessed from January 2024. *Exit:* Canada DCs sourcing CA-Retail and DOTCA for the transitioned brands.

R — Result. At discovery exit (record-from-docs): a scope seventeen approvers could sign, a design of six changes of which five were small, a ten-weeks-of-supply front-load of about 2.5 million units with the DC confirming "no space constraint", and a 99-brand wave plan with a dated pilot. The build fit a single sprint window because the design reused the existing Canada cross-dock process and mailbox locations 751 and 1050 rather than inventing a flow. **Outcome after August 3 — VERIFY** (D2); I will not quote a workload or brand count I cannot source. **Reflection:** goal four — moving inventory-planning work to Canada — left discovery as "review and identify"; it deserved a decision, not a review.

COST VS SPEED — THE OPTIONS ON THE TABLE

OPTION	WHAT IT WOULD HAVE COST	WHAT I CHOSE AND WHY
Make the brands Canada-managed now	Vendor, pricing, planning and compliance work per brand — "at least another 2 years" (p. 4)	Rejected for this year; kept as the long-term goal.
Keep store-level picks in US DCs and add labor	US DC workload growing with both countries; not sustainable even with a new warehouse (p. 4)	Rejected — it is the problem statement.
Cross-dock POs to the Canada DC, Canada allocates (chosen)	Six configuration changes, one medium script; existing mailbox locations and transport process (p. 12, 14–15)	Chosen: the cheapest design that moved the pick from per-store to per-DC.
Automate US↔CA rebalancing and new reporting in the same release	FRAME and reporting scope; would not fit one sprint	Fenced out in writing; rebalancing by manual DC-to-DC transfer (p. 5).
Big-bang transition of all brands	Canada DC absorbing the whole load at once; one defect class across 99 brands	Rejected for a pilot of twenty smaller-volume brands, then two waves (p. 16).

WHO I NEEDED

WHO (DECK P. 22–23)	WHAT I NEEDED	HOW I GOT IT
Steering: Mike Racer, Rosie Pouzar, Kalyan Adavi	The go-live target and the wave sizes	Discovery results with a dated plan and an explicit "go-live target alignment — in progress" line instead of a guessed date.
Business owner Yvonne Kwan; SC Strategy	Scope and the exclusions	Out-of-scope slide; seventeen approvers named on the FSD.
US and CA Planning (Esparza; Gurizzan)	Who plans what after transition	Business-process impact slides — US planner keeps newness/core setup; Canada DP allocates; Canada Planning owns reserves.
UDC / MDC / CA Operations / CA Logistics / US Transportation	Capacity and the physical flow	Volume estimate shared with the DC ("no space constraint"); current XDOCK, ODS and truck processes reused.
FRAME lead, MCS engineering, Blue Yonder architects, QE	A sized design and a test plan in one sprint	The spike flow with requirement IDs; six sized changes.

TRADE-OFF I MADE. Speed and frugality over completeness: a configuration-only design that fit one sprint, at the price of manual rebalancing, samples left on the old path, no brand-differentiation reporting, and inventory-planning workload left where it was. What it bought: a brand cutover start six weeks after FSD sign-off and a Canada DC that absorbed load in waves instead of all at once. **Failure / learning line:** the deck's own status at discovery exit read “Go Live Target Date Alignment — In Progress” — I presented a date (8/3) the steering committee had not yet aligned to; next time the alignment closes before the slide prints.

LP proof lines. Bias for Action — a two-year problem got a one-sprint bridge. **Frugality** — six changes, five small, on existing mailbox locations and truck processes. **Customer Obsession** — the front-load of ten weeks of supply existed so Canadian stores never went dark during a brand's switch. **Deliver Results** — discovery closed early with a sized design and a dated wave plan.

SAFE-SAY. Most attackable number: “About 2.5 million units — that was the ten-weeks-of-supply front-load estimate in the discovery deck, across all transitioning brands; the pilot alone was about 217,000 units.” Source question: “The June 2023 discovery-results deck and the solution spike; I'm named as project manager on the team slide. I have not re-verified the post-launch numbers, so I'm giving you the plan.”

20-SECOND VERSION

Thirteen percent of Canadian store volume was US-managed brands picked store by store in US DCs. I project-managed a ten-week discovery that redesigned it as cross-dock POs to the Canada DC with Canada allocating — six system changes, five small — and a 99-brand wave plan with a twenty-brand pilot fronted by about 2.5 million units of supply. Build fit one sprint; cutover was planned to start August 3, 2023.

PROBING Q&A

What made this a large-scale program if the system change was six items?

The scale was in the operation, not the code: 99 brands, two countries, two US DCs and the Canada DC, planning teams on both sides, transportation, and a ten-weeks-of-supply front-load of about 2.5 million units moved before any sourcing switch. The system work was small because we reused the Canada cross-dock path; the program work was sequencing those moves brand by brand without a store running out.

Why a pilot of twenty, and why the smaller-volume brands?

Because the first defects would be process defects — planner setup, flags, order groups — and I wanted them found on brands where a miss cost little. Twenty omni brands, about 217,000 units, with IT supporting each cutover; then forty and thirty-nine once the seven-step IT procedure had run clean.

How did you protect Canadian stores during a brand's switch?

Order of operations: apply the QH on DOTCA — the deck's term — to create replenishment demand into the US DCs, transfer inventory to Canada, flip MCS sourcing, then release the cross-dock PO. Overage and underage followed the existing US → CA substitution process, and rebalancing stayed a manual DC-to-DC transfer so no one waited on new automation.

What did you fence out, and did anyone push back?

Rebalancing automation, sample flows, new reporting, the Sephora Collection DC and the Canada Capture project — each written on the scope slide with where it would live instead. Pushback came as “while we're here” requests; the answer was the sprint window: anything added moved the August 3 start, and the business preferred the date.

B3 · JAMES · Enabling a new node type twice — the same two programs told as PROCESS design: connectivity, node enablement, capacity signalling, escape routing, configuration governance NEW ANGLE

Interviewer lens: he designs inbound/outbound connectivity, crossdock enablement, escape routing and capacity signalling for new node types, and governs hundreds of configuration changes a week with pre-deployment validation. Tell him the *configuration*, not the council. Facts used here that B1/B2 do not lead with: the TMS warehouse-ID change, the 44-row requirement register as a change manifest, the Frame bridge rows, the Bowser "Dotcom-only" rule reuse, the Harmonized Code feed, the AIM assortment copy, the Locus socket/REST and carton-ID decisions, the network expansion SOW, the Canada network-lane and planner-code setup, the seven-step pre-batch script and the five data sets.
LPs: Dive Deep · Invent and Simplify · Insist on the Highest Standards · Are Right, A Lot. **Headline number:** 44 governed configuration rows across 23 named systems for one node change (record-from-docs); six sized changes — five small — to enable a cross-border cross-dock node (record-from-docs).

60-SECOND PITCH

Twice in two years I enabled a new node type by configuration rather than by code, and both times the discipline was the same: write every change as a row with a system, an owner and a validation step, run the rows in a fixed order, and keep the old identity alive until the new one proves itself. At Utah I turned two warehouse identities into one omni node — new selling location 900 mapped onto inventory location 901 — which meant re-pointing the TMS warehouse ID on inbound POs, giving the order-management and sourcing engines a new source node, re-keying four finance systems, the data warehouse and HR, and bridging the old location to the new one in the planning system until decommission. Forty-four rows, twenty-three systems, one register. For Canada I enabled the Canada DC as a cross-dock sourcing node for US-managed brands: a vendor-to-Canada lane in the network, lead times, load and unload durations, order groups, planner codes and PO-search routing — six changes, five of them small, executed per brand by a seven-step script that runs before the nightly planning batch.

S — Situation. Two node problems. UDC: one building carrying two systemic warehouses, so every connected system — transportation, OMS, sourcing, finance, reporting — held two identities for one dock; storage split by channel; self-transfers between the two sides (council deck p. 3). Canada: the Canada DC was not a sourcing node for US-managed brands, so around 13% of Canadian store volume was picked per store in US DCs and trucked north (discovery p. 4).

T — Task. Design the node changes so that every upstream and downstream connection flipped in a known order with a validation step, nothing deployed that was not on the register, and the exception paths — overage, substitution, rebalancing, robotics failure — had a defined route before go-live. I owned the register and the sequence; the system teams owned the rows.

A — Action.

1. INBOUND CONNECTIVITY

- **UDC:** TMS warehouse-ID change on inbound POs from W801 to W901 (deck p. 9); PO generation and receipt against the single 901 with Dotcom Reserve, Retail Reserve and Uncommitted buckets (rows 4–5); a new put-away tracker so receipt confirmation and put-away postings drive the channel split (rows 7–8, 12–13); receipt processing for reserved 901 POs before the WMS conversion and for leftover 801 POs after it, with an automated 801 → 901 move (rows 20, 25); a Harmonized Code feed to the new WMS (row 22).
- **Canada:** a vendor → Canada DC lane in the FRAME network in addition to vendor → US DC, with network lead time, load/unload durations and case-pack setup per DC (discovery p. 10, 19); the existing XDOCK PO path through

mailbox locations 751 and 1050 reused — no new locations (p. 12).

2. OUTBOUND CONNECTIVITY AND NODE ENABLEMENT

- **UDC:** OMS and Yantriks set up W901 as the new source DC; fifteen digital, finance and reporting systems re-pointed from 800/801 to 900/901 (rows 28–44); the Bowser order-optimisation feed made to treat “Dotcom only” US SKUs the way “CA only” SKUs are already handled for Canada — a rule reused, not written (row 17); AIM one-time copy of all dotcom assortments including samples from 800 to 900 (row 18); sales history and forecast copied from DC-0801 to DC-0900 (rows 26–27).
- **Canada:** Canada DC becomes the sourcing DC for CA-Retail and DOTCA for transitioned brands (the “flip the switch in MCS” step, p. 16); Canada DP allocates newness and core like a Canada-managed brand; auto-approval holds stay configured at the CA retail DC (p. 11).

3. CAPACITY SIGNALLING

- **UDC:** the two-channel reserve split is the capacity signal — the merch reserve is channel-split on on-order postings to Frame and inventory postings to Merlin (rows 12–13); during the interim, Frame auto-copies on-hand, on-order and the dotcom split % from 801 to 900 so planning sees one node before the floor does (rows 19, 21); Locus volume share between bots and manual carts was built as a dial against a published 98% pick-accurate gate (Apple C3, record).
- **Canada:** the volume estimate was shared with the DC before design closed — ten weeks of supply, about 2.5 million units, “no space constraint” (p. 16); brands moved in waves of 20 / 40 / 39 so the Canada DC absorbed load in steps (p. 16); FRAME projections moved from US-DC outbound to brand projections against the CA DC, summed for the brand (p. 11); comingled allocation changed so unallocated inventory no longer auto-flows to DOTCA for these brands (p. 14).

4. EXCEPTION AND ESCAPE ROUTING

- **UDC:** a negative-merch-reserve path and an inventory-out-of-balance variance report in the put-away tracker (rows 9–10); lost/found included in the May 1 conversion script (row 24); robotics escape = throttle to manual carts when week two measured 94% against the 98% gate (record).
- **Canada:** overage, underage and substitution follow the existing US → CA process (p. 12); rebalancing stays a manual DC-to-DC transfer outside FRAME (p. 5); samples stay on the old US-DC → CA-store path with their own ODS (p. 12); PO review in USD for a Canadian destination handled explicitly (p. 15).

5. CONFIGURATION GOVERNANCE AND PRE-DEPLOYMENT VALIDATION

- **The register:** 44 numbered rows, each with a phase/track prefix, one change, one system (deck p. 13–14) — and the systems-impacted table in front of it (p. 9). The same rows drove the build plan and the cutover runbook (Apple C4, record).
- **Order of execution for Canada:** business supplies five data sets (dept/brand/vendor; planner codes by dept/class/brand; load/unload durations; case packs; network lead time); IT runs seven steps before the FRAME nightly batch — delete the replenishment strategy, create CA Retail and CA Virtual DC SKUs with initial-PO and newness flags and order groups, set XDOCK flags, set planner codes, upload durations/case packs/lead times (p. 19). Per brand, four steps: apply QH → transfer inventory → change sourcing → release XDOCK PO (p. 18).
- **Validation before volume:** dated E2E completions per flow — inbound Nov 22, dotcom Dec 20, retail Jan 15 planned / Jan 30 actual (deck p. 10; Apple C1); Locus interfaces unit-tested with simulated data before a physical bot rolled, then floor testing Feb–Mar 2025 with UAT 2/28–3/15 (Locus track status; Apple C3); decisions recorded on the Locus track — sockets rather than REST for the API, tote-type mapping and a base-36 outbound carton-ID sequence requested of Locus, customer-owner configuration SEPHORA-RTL versus global variables (Locus track p. 1).
- **Physical readiness as configuration:** the Salt Lake City network expansion SOW (Nov 19, 2024) added IDF3 and IDF4, 31 access points (APs 19–49) and three fiber runs to the existing Locus rack — wireless coverage was a pre-deployment check, not a go-live surprise (SOW p. 8–9).
- **Change freeze and fence:** comingle reserve calculations frozen; MCS decommission routed to the Global ERP project (deck p. 4); for Canada, rebalancing, samples, reporting, Sephora Collection and Canada Capture routed to

other FSDs (p. 5).

R — Result. UDC: every connected system flipped on the register's rows; both go-lives with zero customer-facing incidents; the retail E2E slip was re-slotted in the open rather than absorbed; +15% processing efficiency measured by DC Ops (record). Canada: the node enablement sized at six changes, five small; a repeatable per-brand script with a data checklist that let non-specialists — planners — supply the inputs (record-from-docs; post-launch outcome VERIFY). **Reflection:** the retail E2E date on the register was wrong by two weeks because robotics physical testing was planned off the vendor's calendar, not the floor's — I now put a physical-readiness row in the register with its own owner.

WHO I NEEDED

WHO	WHAT I NEEDED	HOW I GOT IT
TMS / transportation	Warehouse-ID flip on inbound POs; ODS for Canada DC reused	One row (p. 9); current ODS and truck process left unchanged (discovery p. 12).
MCS / FRAME / Merlin / Bowser / AIM owners	Location, reserve, tracker, copy and script rows	Rows 1–27 and the Canada six changes, each sized by its owner.
Digital and Finance system owners (15 systems)	Re-point 800/801 → 900/901 by the dotcom E2E date	Rows 28–44; the shared E2E date.
Locus and the WMS team	API style, carton-ID sequence, tote mapping, coverage	Decisions logged on the track status; SOW for the network expansion.
US and CA planners	The five data sets per brand, on time	A checklist on the execution slide; IT runs the script, planners supply data.

TRADE-OFF I MADE. Reuse over elegance: the Canada node reused the existing cross-dock path, mailbox locations and ODS, and the UDC node reused the Canada “CA-only” rule for “Dotcom-only” SKUs — fewer rows, fewer unintended deployments, at the price of carrying a bridge (Frame auto-copy 801 → 900) and manual rebalancing for a period. **Failure / learning line:** the register listed the retail E2E as January 15 and it completed January 30; physical robotics readiness was not a row with an owner, so its slip arrived as a vendor message rather than a planned re-slot.

LP proof lines. Dive Deep — I can name the row that bridges the two locations during the interim. **Invent and Simplify** — a “Dotcom-only” rule borrowed from Canada instead of a new one. **Insist on the Highest Standards** — a dated E2E per flow and a published robotics gate before volume. **Are Right, A Lot** — the waves of 20 / 40 / 39 and the fenced exclusions were sized from data the DC and planners gave, not from a guess.

SAFE-SAY. Most attackable number: “Forty-four requirement rows across twenty-three named systems in the council appendix — that's the count on the slide, not a line-item count in Jira.” Source question: “The Architecture Council sign-off deck of July 31, 2024, the Canada discovery deck of June 2023, the Locus retail track status and the Locus network SOW.”

20-SECOND VERSION

I enabled two new node types by configuration: one omni node at Utah — forty-four governed rows across twenty-three systems, a TMS warehouse-ID flip, a planning bridge between old and new locations until decommission — and the Canada DC as a cross-dock sourcing node for US-managed brands — six changes, five small, executed per brand by a seven-step pre-batch script with a five-item data checklist. Both ran on a register, a fixed order and a validation step before volume.

PROBING Q&A

How did you prevent an unintended deployment across 44 rows and 23 systems?

Nothing deployed that was not a row, every row had one system and one owner, and the rows were grouped by the E2E date that would prove them — inbound, dotcom, retail. The register was the manifest; the dated E2E was the acceptance test; the weekly review read open rows by severity. A change that arrived without a row went back to get one.

What was the escape route when the robotics layer under-performed?

A dial, built before the bots arrived: volume share between bots and manual carts against a 98% pick-accurate gate. Week two measured 94%, about 30% of volume went to carts while the zone logic was corrected, full automation in week three. The register had the gate; the floor had the carts (record).

How would a non-specialist execute a Canada brand transition?

They supply five data sets off a checklist — brand list, planner codes, load/unload durations, case packs, lead times — and IT runs a seven-step script before the nightly batch. The order is fixed: QH, transfer, sourcing flip, cross-dock PO. The specialist knowledge sits in the script and the order, not in the person.

Where did capacity signalling fail or nearly fail?

At Utah, the interim: planning saw one node from January while the floor had two until May. The Frame auto-copy rows carried the signal, and daily reconciliation watched for drift. The near-miss was reporting — two systems of record for four months with every report declaring its source; the reporting workstream started in month three and should have been on the register from day one.

B4 · VENKATA · “One promise per customer, in both countries” — the same two programs as a PRODUCT / customer story NEW ANGLE

Interviewer lens: Principal PM, FBA — customer problem, requirement prioritisation, what we chose not to build, success metrics, adoption. Facts led with here that B1–B3 do not: the five customer benefits on the objectives slide, the 44 rows triaged into go-live / fast-follow / enhancement (the issues log's own categories), the no-historical-conversion decision as a product call, the React gift-card screens as adoption evidence, the Canada pilot's brand mix (kits 39% of pilot units), the long tail of 2.5M units protecting store availability, and the planning-workload question we deliberately left open.

LPs: Customer Obsession · Invent and Simplify · Frugality · Learn and Be Curious. **Headline numbers:** zero customer-facing incidents through two go-lives (record); about 13% of Canadian store volume moved from per-store picks to one bulk flow (record-from-docs — plan).

60-SECOND PITCH

The product problem in both programs was the same sentence: the customer was being promised from the wrong place. In Utah, a store and a dotcom shopper could want the same unit in the same building and be told two different truths, because the building kept two books and two shelves. In Canada, a store's newness waited on a US warehouse picking it store by store. I treated both as product work — define the customer problem, rank the requirements, decide what not to build, name the metric, and plan adoption. Utah's answer was one pool with two selling identities — forty-four requirements, ranked so the go-live set was the minimum that made one promise true, with the rest as fast-follows; we explicitly did not convert history, did not touch reserve math, and did not rebuild the warehouse's reporting. Canada's answer was a cross-dock path that already existed, with twenty smaller brands first so the mistakes were cheap. The metric I held myself to was the one the customer feels: zero customer-facing incidents across both Utah go-lives, and a ten-week supply front-load so no Canadian store went dark during a brand switch.

S — Situation. **Utah:** two systemic warehouses in one building meant duplicate receiving, split storage, systemic self-transfers and two planning views — the objectives slide lists the five customer-side benefits we were chasing: better inventory planning and ordering, one receiving flow, better storage utilisation, fewer internal transfers, and a template for the Midwest DC (council deck p. 3). **Canada:** “Canada is growing at a very high pace”; around 13% of store volume was US-managed brands picked per store in US DCs; the structural fix was two years away (discovery p. 4).

T — Task. Own the requirement set and the customer outcome for both: what the minimum lovable change was, which requests waited, and what number would say we were done.

A — Action.

- **Customer problem, written first.** Utah: “one inventory, one promise, two channels” — a single location 901 with Dotcom selling location 900 mapped onto it (deck p. 4). Canada: “buy it once for Canada, pick it once in Canada” — cross-dock POs to the Canada DC, Canada allocates (discovery p. 8).
- **Requirement prioritisation.** The council appendix carried 44 rows in three tracks (deck p. 13–14); the program then ran them through one issues log whose own categories were Go-Live 331, Fast Follow 77, Enhancement 36, Pre-Go-Live 29 and HSE readiness 12 — a visible, defended deferral list rather than a quiet one (issues log, record-from-docs). Canada: six system changes, five small, and a seven-item transition plan; the “review and identify” on planning workload was left open on purpose and said so (discovery p. 4, 14–16).
- **What we did NOT build.** Utah: no conversion of historical 801/800 transactions (p. 4); no change to comingle reserve calculations (p. 4); no MCS decommission in this program (p. 4); no US-tuned reserve engine — Canada's functions replicated 100% (p. 4); no new reporting platform for the interim (Apple C1, record — and our miss).

Canada: no rebalancing automation, no bulk-ship for samples, no brand-differentiation reports, no Sephora Collection DC, no Canada Capture changes (p. 5).

- **Success metrics, chosen before launch.** Utah: zero customer-facing incidents (the bar), processing efficiency (DC Ops' measurement), a 98% pick-accurate robotics gate with 99% stretch, and a go/no-go that read Blocker + Critical = 0 (record). Canada: US DC workload moved from per-store picks to per-DC bulk for transitioned brands, Canada DC absorbing in waves, stores never short during a switch — the ten-weeks-of-supply front-load of about 2.5 million units was the availability insurance (p. 16).
- **Adoption.** Utah: the new WMS was chosen partly because a portal, Android and React front end makes user rollouts easier than a thick client (p. 3) — and the React gift-card screens in the appendix show the extension path in use on warehouse W901 (p. 15–17). Canada: existing US → CA-managed transition training material revised rather than new training invented; IT supported each pilot-brand cutover; planners kept their existing newness and core setup steps with one extra PO to review (p. 10, 16).

R — Result. Utah: two go-lives, zero customer-facing incidents; processing efficiency up fifteen percent by DC Ops' measurement; one pool, one promise, two channels (record). The deferred list stayed visible — 85.4% of 836 issues closed, the rest owned (record). Canada: a scope seventeen approvers signed, a pilot of twenty omni brands — about 217,000 units, 671 SKUs, with Sephora Favorites Kits alone 39% of pilot units — and a dated wave plan to 99 brands; post-launch outcome VERIFY. **Reflection:** I prioritised the warehouse's requirements well and the analyst's badly — the interim reporting experience was a customer too, and it got a workstream in month three instead of day one.

WHO I NEEDED

WHO	WHAT I NEEDED	HOW I GOT IT
DC Ops (the operator-customer)	The bar and the measurement	Zero-incident bar in the charter; they owned the +15% measurement.
Planning (US and CA)	Agreement on what stayed manual	Written “what we are not building” lines; reserve math frozen; rebalancing manual.
Digital / OMS product owners	One omni source node and no history conversion	Rows 28–44; the no-conversion decision on the scope slide.
Floor users	A UI they would adopt	Portal/Android/React; gift-card React extension; training material revised not reinvented.
Canadian stores (through CA Operations / Logistics)	No gap in supply during a brand switch	Ten-week front-load before the sourcing flip; overage/substitution on the existing process.

TRADE-OFF I MADE. Fewer features, sooner, with the deferrals written down: no history conversion, no reserve-math improvements, no rebalancing automation, no sample bulk-ship — chosen so the minimum change that made one promise true could ship on the staged dates. The cost was carried by analysts (two systems of record for four months) and by planners (manual rebalancing). **Failure / learning line:** the analyst was a customer I under-served; next time the interim reporting experience is a P0 row, not a fast-follow.

LP proof lines. Customer Obsession — the bar was the customer's experience (zero incidents; no store short), not the project's dates. **Invent and Simplify** — one pool with two identities instead of two warehouses; a cross-dock path reused instead of a new flow. **Frugality** — five of six Canada changes small; a front end chosen for cheap rollouts. **Learn and Be Curious** — profiled both books (SKU overlap, order profiles) before designing, so the comingle benefit was sized rather than assumed.

SAFE-SAY. Most attackable number: “Thirteen percent is the discovery deck's figure for the share of volume to Canada stores that was US-managed — I'm quoting the deck, not a measurement I ran.” Source question: “Two decks from the programs — the July 2024 Architecture Council sign-off and the June 2023 Canada discovery results — plus the program's issues log; the fifteen percent is DC Ops' number.”

20-SECOND VERSION

Both programs fixed the same customer problem — being promised from the wrong place. Utah became one pool with two selling identities, forty-four requirements ranked into go-live and fast-follow, with history conversion, reserve-math changes and a reporting rebuild explicitly not built; zero customer-facing incidents across two go-lives. Canada reused an existing cross-dock path, twenty small brands first, ten weeks of supply moved ahead so no store went dark.

PROBING Q&A

How did you decide what was go-live versus fast-follow?

One test: does the customer's promise become false without it? Location setup, PO creation with channel reserves, the conversion script, the OMS source node and the finance re-keys passed. Reserve-math improvements, history conversion and better reporting failed the test and went to the deferred list in writing. The log's own categories — 331 go-live rows against 77 fast-follows and 36 enhancements — are the record of that triage.

Who was the customer you got wrong?

The analyst. For four months every report had to declare which system of record it read. We got through it, but the interim analytics deserved a workstream from the first deck. It is the one thing I would change in the council pack.

Why not convert the historical dotcom transactions to the new location — isn't that a worse experience for anyone reading history?

It is a worse experience for the analyst and a safer one for the shopper. Converting history would have touched every downstream system's past rows for a benefit nobody buying from the building would feel; we wrote “no conversion of historical transactions” on the scope slide and copied forward only what planning needed — sales history and forecast from 801 to 900.

What did adoption look like for the Canada planners?

Almost nothing new to learn by design: the US planner keeps the same newness and core setup, sees one extra PO for CA-Retail in the review, and Canada's planners allocate the brand exactly like a Canada-managed one. The specialist steps live in IT's seven-step script. I can't quote the post-launch adoption figure — that's on my verify list.

B5 · ROCKY (failure answer) · The date I printed on the council slide and missed — FSD “Jul 26” signed Aug 14 NEW — FAILURE, FULL STAR

LPs: Earn Trust · Ownership · Dive Deep. **Numbers:** planned Jul 26 (deck p. 10) → signed Aug 14 (Apple C4, record) — about three weeks; upstream build already open since Jun 9 (deck p. 10). **Why this failure and not the Locus slip:** the Locus slip is already promised in Rocky's Bar Raiser bank (F4); this one is on no other page and the deck is the evidence.

60-SECOND PITCH

The failure I'd give you is on my own slide. On July 31, 2024 I presented the UDC dual-inventory architecture to the council with a timeline that showed “FSD sign-off July 26” — five days earlier — and the functional spec was actually signed on August 14. I had under-counted how many functions needed a second read once the 44-row appendix made their changes concrete: the fifteen digital and finance systems being re-keyed from 800/801 to 900/901 each wanted their row re-read against their own release calendar. Meanwhile the merchandising build had been running since June 9 on the discovery design. What I did about it: said the date had moved, in the same forum, the week it moved; kept the at-risk build fenced to location setup and PO creation; held the January 15 and May 5 go-lives, which did hold. What changed in me: discovery results and the FSD now close together before I print a date, and the sign-off list is counted by name before the slide, not after.

S — Situation. Late July 2024. The council deck's timeline (p. 10) carried “Discovery Results Jul 18” and “FSD Sign off Jul 26” as plan markers; by the meeting on July 31 neither had closed, and the MCS and MCS/FRAME tracks had been in build-and-test since June 9.

T — Task. Close the FSD without letting the open spec become an excuse to silently re-scope, without stalling a build already five weeks in, and without moving the January go-live.

A — Action. I named the slip in the weekly two-block status the week it was clear, with a date, not a hope. I split the sign-off: the upstream merchandising rows (1–27) whose owners had already estimated and started were confirmed first; the digital and finance rows (28–44) got the re-reads their owners asked for, one system at a time, against the dated dotcom E2E of December 20 as the only deadline that mattered. I kept the at-risk build fenced to the rows discovery had stabilised and did not let the WMS-conversion, outbound, finance or EDW tracks open until August 1. The FSD and the discovery-results deck were signed together on August 14 (record).

R — Result. Three weeks late on the spec; zero days late on the go-lives — January 15 and May 5 held, zero customer-facing incidents (record). No scope entered during the gap without a row and an estimate. **What changed:** I now count the sign-off list by name before a date goes on a slide, I close discovery results and the FSD as one gate, and when build runs at risk I write which rows it may touch into the pack. **What I'd do differently:** show the council the honest date — “mid-August” — with the at-risk build bars next to it. The council would have signed the same architecture; I would not have spent three weeks explaining a slide.

TRADE-OFF I MADE. Keep the fenced build running on an unsigned spec (speed) versus pause until signature (certainty). I kept it running: the exposure was rework on rows owned by teams who had written the estimates themselves; the alternative was a January date that could not hold. **Learning line:** an optimistic date on a sign-off slide costs more trust than the slip itself.

LP proof lines. Earn Trust — the slip was announced in the same forum that saw the slide. **Ownership** — the date was mine, the under-count was mine, the fix was mine. **Dive Deep** — the cause was the 44-row appendix making fifteen downstream re-keys concrete; I can name the rows.

SAFE-SAY. “The council deck targeted July 26 for the FSD; it was signed August 14 — about three weeks. The go-lives did not move.” Source: “The July 31, 2024 council deck's own timeline slide, and the signed FSD date in my program record.”

20-SECOND VERSION

I printed “FSD sign-off July 26” on the council slide and signed it August 14 — I'd under-counted the downstream re-reads that a 44-row appendix triggers. I said so the week it moved, fenced the build that was already running to the rows discovery had stabilised, and held both go-lives. Now the sign-off list is counted by name before a date is printed.

PROBING Q&A

Why was build running before the spec was signed at all?

Because the January 15 PO-creation go-live needed the merchandising tracks to start in June, and their rows had been through discovery with their owners. I fenced it to location setup and PO creation and kept every other track closed until the day after the council. That was a conscious trade; the optimistic date on the slide was not.

Did anyone use the three weeks to push scope?

Yes — “while the spec is open” requests arrived. The answer was that nothing entered without a row and an estimate, and the out-of-scope lines on the scope slide were already signed by the council. The gap added re-reads, not scope.

What did the council think when the date moved?

They had signed the architecture, not the FSD date; the slip was a steering conversation. It cost me explanation time and some credibility on dates, which I bought back by holding January 15 and May 5.

What is the standing control that proves the lesson stuck?

On the Canada program the discovery deck carried “Go-live target date alignment — in progress” as a printed status line instead of a date pretending to be aligned — and in every pack since, the sign-off list is counted by name before a date goes on a slide.

B6 · JAMES (near-miss / reversed plan) · The retail E2E that moved from January 15 to January 30 — a vendor slip re-slotted in the open NEW — NEAR-MISS, FULL STAR

LPs: Insist on the Highest Standards · Earn Trust · Bias for Action. **Numbers:** planned Jan 15 (council deck p. 10) → completed Jan 30/31 (Apple C1/C3, record); Locus retail testing slipped three weeks (Apple C2, record); program status YELLOW with UAT 2/28–3/15 (Locus track, record-from-docs); week-two 94% against a 98% gate, about 30% throttled, full volume week three (record). **Routing:** told to James as a pre-deployment-validation lesson; Rocky has the same slip in his Bar Raiser bank as F4 — do not tell him both.

60-SECOND PITCH

Here is a plan date I reversed in public. The council deck I signed in July 2024 showed retail outbound end-to-end testing complete on January 15, 2025 — the last of three dated E2E gates. Retail outbound was the Locus robotics flow, and by December the robotics track was yellow: physical and hardware readiness sessions were still being scheduled, the API style was still sockets-versus-REST, and Locus needed three more weeks of retail testing. I had two options: compress user acceptance testing to protect the slide, or move the date and show the move. I moved it — retail E2E completed at the end of January — re-slotted it in the plan's revision sheet where every owner could see it, and refused to shorten UAT. Then the ramp itself tested the gate: week two measured 94 percent pick-accurate against a published 98, I throttled about 30 percent of volume to manual carts while the zone logic was fixed, and we were at full automation in week three. The combined go-live on May 5 did not move.

S — Situation. December 2024 – January 2025. The council timeline (p. 10) set the retail outbound E2E for January 15. The Locus retail track status read YELLOW: site-layout and hardware-readiness sessions pending, LocusNet install and configuration open, API endpoint alignment leaning to sockets over REST, tote-type and carton-ID mapping requests outstanding, UAT pencilled for 2/28–3/15 (Locus track p. 1). The network expansion for coverage — IDF3/IDF4 and 31 access points — had only been specified on November 19, 2024 (SOW p. 8).

T — Task. Protect the combined go-live and the zero-incident bar without pretending the January 15 date was real, and without compressing the validation that stood between a robot and a store order.

A — Action. I took the three-week ask to the weekly steering read the week it surfaced, with the choice priced: compress UAT and inherit a defect class in May, or re-slot retail E2E to end of January and keep UAT whole. Steering took the re-slot. I rewrote the dated chain in the plan's revision sheet rather than absorbing it into weekends, kept the interfaces on the ladder — unit tests with simulated data before any physical bot, then floor testing in February–March — and kept the gate that would judge the ramp: 98% pick-accurate throughput, 99% stretch, with the bot-versus-cart share built as a dial. When week two read 94%, the dial did what it was built for.

R — Result. Retail E2E completed January 30; UAT ran whole; the combined go-live on May 5 held; zero customer-facing incidents; full automation in week three; Locus stayed about a tenth of the issues log (record). **What changed:** physical readiness — power, coverage, server install, mapping — is now a row with an owner on the register, not a line inside the vendor's plan; a date that depends on a vendor's floor work gets a readiness checkpoint four weeks ahead of it.

TRADE-OFF I MADE. A visible two-week slip on a council-dated milestone versus an invisible compression of acceptance testing. I took the visible slip. Cost: a yellow track on the dashboard for two months and a conversation with steering; benefit: a validation window that found the zone-contention problem before volume did. **Learning line:** the January 15 date was the vendor's calendar, not the floor's — a readiness row with its own owner would have moved the date in November, not December.

LP proof lines. Insist on the Highest Standards — UAT was not shortened to save a slide. **Earn Trust** — the slip went into the revision sheet, not the weekends. **Bias for Action** — the throttle fired in week two on a number, not a

debate.

SAFE-SAY. “The council deck planned retail E2E for January 15; it completed at the end of January after Locus asked for three more weeks of retail testing — the combined go-live did not move.” Source: “The July 31, 2024 council timeline, the Locus retail track status page, and my program record.”

20-SECOND VERSION

The council plan said retail E2E on January 15; the robotics track went yellow and needed three more weeks. I moved the date to the end of January in the open rather than compress UAT, kept the 98% gate, throttled to carts when week two read 94, and held the May 5 go-live with zero customer-facing incidents. Physical readiness is now its own row with its own owner.

PROBING Q&A

Why not compress UAT by two weeks — it is only two weeks?

Because the two weeks were the only window where a bot's pick would be checked against a store's order before real volume. Compressing it trades a visible slip in January for an invisible defect class in May, in a program whose bar was zero customer-facing incidents. The gate caught zone contention in week two; a shorter UAT would have met it in a store.

What exactly was still open on the robotics track in December?

On the status page: site layout and hardware readiness sessions, circuit access, server install, bots delivered, Locus points mapped; software — LocusNet install and configuration, customer-owner configuration for retail; integration — sockets versus REST, tote-type mapping, a request that the first two characters of the outbound carton ID allow a base-36 sequence; UAT dated 2/28 to 3/15. That is a list, not a feeling, which is why steering could decide in one read.

Was the network expansion on the critical path?

It was a dependency I should have had on the register earlier: the SOW for IDF3/IDF4 and 31 access points is dated November 19, 2024, two months before the E2E date. Coverage was ready for floor testing in February; the lesson is that it was ready because the vendor was good, not because my plan demanded it.

How did you keep the slip from spreading to the other two E2E gates?

Inbound had completed November 22 and dotcom December 20 — both green before the retail ask arrived. The chain was per flow by design, so a retail slip moved the retail date and nothing else; the PO-creation go-live on January 15 did not depend on retail outbound.

Who hears which variant — the three interviewers compare notes

MATERIAL	ROCKY 10:00 (PROGRAM / INFRASTRUCTURE)	JAMES 11:00 (PROCESS / PLACEMENT / CONFIGURATION)	VENKATA 12:00 (PRODUCT / CUSTOMER; BAR RAISER DEPTH)
UDC dual inventory	**B1** — gate chain, council consensus framework, cutover runbook, rollback triggers, hypercare exit. Headline: zero incidents; +15%.	**B3** (UDC half) — TMS W801 → W901, 44-row register, Frame bridge rows, Bowser rule reuse, HC feed, E2E per flow as acceptance. Headline: 44 rows / 23 systems.	**B4** (UDC half) — one promise, go-live vs fast-follow triage (331/77/36), what we did not build, React adoption. Headline: the deferred list stayed visible.
Architecture Council	**B1** leads with it: pre-wire, decision rows, two touchpoints, written fence.	One sentence only: “the register came out of the council appendix.”	One sentence only: “the council signed what we would not build.”
Canada bulk ship	**B2** — cross-border program: cost-vs-speed options, six changes, waves 20/40/39, launch gates. Headline: 13%; 2.5M units.	**B3** (Canada half) — node enablement by configuration: network lane, planner codes, seven-step pre-batch script, five data sets, escape routing. Headline: six changes, five small.	**B4** (Canada half) — store availability during a switch, pilot brand mix (kits 39%), the planning-workload question left open. Headline: twenty small brands first.
Failure	**B5** — FSD date printed Jul 26, signed Aug 14. (Rocky's bank F1 the UAT crash remains the alternative.)	**B6** — retail E2E Jan 15 → Jan 30; readiness row. (James's packet J8 remains the alternative.)	Use Venkata's own packet failure (G3 / G1 family). If pressed on UDC: the interim-reporting miss inside B4, one line.
Locus robotics	Bank F4 / PM packet P3 own the throttle story; B1 mentions the gate in one line.	Inside B6 as validation evidence; B3 as the escape route.	Not told unless asked; one line on the 98% gate as a customer-protecting metric.
Numbers never to collide	“About two dozen named systems / seven families / about a dozen domains” — same phrasing in every room. “May 5” and “January 15” — same dates in every room. “13%”, “2.5 million units”, “20 / 40 / 39” — Canada plan numbers, always “the plan at discovery exit.” Never attach a region to the Elementum “six sites” bench line; never a multiplier; never a Canada outcome.		

C1. Alignment patch list for the other packets (not edited by this pack; also at /tmp/udc-canada-alignment-patchlist.md)

Checked at 21:50, 22:05 and at final render (Oct 29). On disk at final check: James packet (amazon-nacf-panel-4-cabreros-process-star-kimi-k3), Rocky Bar Raiser bank (…goforth-bar-raiser-bank-star…), Apple-delta add-on. Not yet on disk: Rocky PM packet (…goforth-pgm-star…), Venkata main (…josyula-star-bar-raiser…), Venkata extras (…josyula-extra-stories-star…). For files not yet present, the rows below are keyed to the v2 Rocky packet (amazon-nacf-panel-3-goforth-kimi-k3) their authors are reusing, and to the story IDs the bank says they will contain (P1 UDC, P3 Locus, P5 council).

D2. VERIFY list — facts in none of the sources, each with the safe sentence

FACT TO CONFIRM WITH RAJESH	SAFE SENTENCE UNTIL CONFIRMED
Did the Canada brand cutover start on Aug 3, 2023; how many of the 99 brands transitioned and by when; what the US-DC workload effect was.	“I'm giving you the plan at discovery exit — a twenty-brand pilot from early August and two waves to ninety-nine brands; I have not re-verified the post-launch count, so I won't quote one.”
Whether Rajesh presented the July 31 council deck himself (the deck names no presenter; Apple C4 says he owned the case).	“I owned the council case and the pack; the architecture diagrams were Enterprise Architecture's.”
Whether the FSD slip (Jul 26 → Aug 14) was caused by the downstream re-reads as B5 states (the deck shows the dates; the cause is reconstructed from Apple C4's pushback list).	“The slide said July 26 and we signed August 14 — the re-reads on the digital and finance rows took the time; I'd rather own the date than the excuse.”
Whether the under-two-blockers-a-day hypercare bar was formally the UDC exit criterion (GFiber v8 only).	“Hypercare exited on a number — blockers per day under a threshold, sustained — the same discipline as the JDA migration.”
Exact rollback thresholds (sync < 99% for 4 h; p95 > 2× for 1 h) for the UDC go-lives (resume supports triggers; thresholds are GFiber-only).	“Two numeric triggers on sync rate and order-flow latency, armed per interface; neither fired.”
Whether the May 1 conversion ran as a single-day move (row 24 says “100% 05/01 transfer”) and the combined go-live was May 5 as planned.	“The inventory moved under the conversion script at the start of May and the combined go-live was the first week of May.”
Meaning of “QH” on the Canada transition plan.	Use the deck's word: “apply the QH on DOTCA to create replenishment demand.”

D3. Questions to ask — two per interviewer, made possible by these documents

INTERVIEWER	QUESTION
Rocky Goforth	“When Amazon Infrastructure takes a building through an architecture or design review, is the gate a sign-off on a pack like the one I described — current state, future state, impact table, timeline — or is it continuous? Where do you see teams lose the most time: before the gate or after it?”
Rocky Goforth	“On a building launch, who owns the decision to let build start before the design is formally approved — and how do you fence it? I ran upstream build five weeks at risk on UDC and I'd like to know how your teams govern that.”
James Cabreros	“When you enable a new node type in the policy platform, is there a single change register the way my 44-row council appendix worked — one row per system per change — and how do you keep the pre-deployment validation tied to it at hundreds of changes a week?”
James Cabreros	“For cross-border or cross-network sourcing — the Canada DC becoming a sourcing node for US-managed brands is my example — what does the capacity signal look like in your world: does the receiving node publish its own absorb rate, or is it planned from the sending side?”
Venkata Josyula	“In FBA, when a change improves the seller or shopper promise but worsens an internal customer's experience for a while — my example is analysts running on two systems of record for four months — how do you weigh that in prioritisation, and who gets to say no?”
Venkata Josyula	“Both my programs chose a smaller pilot of lower-volume cohorts first — twenty small brands in Canada. How does FBA pick pilot cohorts for a placement or inventory-model change: by risk, by volume, or by seller readiness?”

> **Closing honesty note.** Everything in B1–B6 is lived record or record-from-docs except where labelled user anchor or VERIFY. No design case appears in this pack. The literal strings the integrity rule bans do not appear; the systems-count wording and the Canada plan numbers are phrased identically in every story so the three interviewers hear the same facts from different angles.

AMAZON L6 · SENIOR SUPPLY CHAIN MANAGER · NACF SUPPLY CHAIN · PACKET 3B (COMPLEMENT TO THE ROCKY PROGRAM-MANAGEMENT PACKET)

The Bar Raiser Bank — Rocky Goforth

More examples, all 16 Leadership Principles, three-level probes, failures — every answer in STAR

Rocky Goforth — Senior Manager, Amazon Infrastructure · BAR RAISER

Wants an engineering / program leader: large-scale deployment, program cadence, stakeholder management, cost-versus-speed calls

Friday Oct 30 · 10:00 am PDT · first interview of the day

CANDIDATE: RAJESH RISHIYUR CHANDRASEKARAN · BUILT THU OCT 29, 2026 · READ WITH: AMAZON-NACF-PANEL-3-GOFORTH-PGM-STAR-KIMI-K3 (PRIMARIES P1–P7)

The one-line strategy. Rocky is the bar raiser, so he will not stay on one story. He will pick a Leadership Principle, ask a question from Amazon's own bank, and dig three levels: *what exactly did you do · what did the data say · what happened after*. The program packet (P1–P7) gives him the big UDC and WMS programs. This bank gives him **nine more real stories (R1–R9)** and **four real failures (F1–F4)** that were not told to the hiring manager or Ryan and are not the stories Venkata will hear. That way the loop never hears the same story twice.

Order to reach for them. P1 UDC launch → R1 routing guide (25 European locations) → R5 observability on a nine-team platform → R6 two programs, one ruler → R2 carrier-bid cycle → R4 Customs ownership split → R7 the triage agent → F1 the UAT that crashed (only when he asks for a failure).

Three opening sentences. (1) "The noise said the carriers were late; three years of shipment data said we could not even measure late. Data quality was about 55%, not the 40% on the report, so I fixed the measurement before the engine." (2) "Six systems and nine teams, and no ID tied an event to its source, so every blocker took two to four hours to find. I proposed one trace ID end to end, and the time to fix a blocker bug fell by half." (3) "Leadership pulled a go-live forward a month and moved my engineers onto it, so I ran both programs on one RAID log, one 45-minute daily forum and one blocker ruler, and both landed."

Five numbers never to get wrong.

1. **About $8M validated freight savings across 25 European locations** (record, Apple F2). The Austria pilot was about $500K a year at one site. Never say "$1M", never say "400-plus lanes".
2. **Data quality: about 40% reported, about 55% true, then 99%**, "within a quarter". Apple says two months and the master says three, so I say "within a quarter".
3. **Time to fix blocker bugs down 50%**. It used to take two to four hours just to find which system held the bug, across six systems and nine teams (record-from-docs, SV 3PL ingestion one-pager).
4. **$25 to $0.40 per triaged incident, a 98% cut, with 100% citation coverage** (record, Apple I1). This was my own independent build, not an employer program.
5. **About $200K a month per DC was at stake** in the compressed go-live (record, Apple B3). The compressed program landed inside four weeks. Quote the monthly rate first and "about $1M per DC" only if asked.

Sources: master packet, GFiber v8, Apple PM III v11, Flexport and UDC program docs, AIQB. Full SOURCE TRACE at the back. Basis labels: **record** · **record-from-docs** · **user anchor** (GFiber v8 only) · **modeled** · **illustrative**. No detailed math tables.

1 · Story inventory & allocation — every real story, who already heard it, what is FREE for Rocky

Legend: **Told** = told today to Snigdha Tripathy (HM) or Ryan Hoerger · **P#** = primary in Rocky's program packet · **Josyula** = likely in Venkata's 12:00 bank (SV/Crux as product, S9, S13–S16, Walmart design cases, failure arcs) · **FREE** = nobody has it, so use it first. Any reuse is told from a *different angle with different facts* and flagged. **Net:** six FREE (R1, R2, R3, R4, R6, R7), three different-angle reuses (R5, R8, R9), four failures (F1–F4). No design case needed. The UDC arch-council deck and the Canada bulk-ship discovery go to the separate UDC/Canada story pack.

2 · Bar Raiser playbook NEW

What a Bar Raiser is actually testing

LP depth, not LP coverage	One story, three levels down. A story that only works at level one counts as a "mild concern" in the AIQB rubric. The proof is a mechanism you can name (the gate, the ruler, the log), plus the number it moved and the date.
Ownership vs "we"	Every sentence that carries a claim starts with "I". Every sentence about the build names who built it. He will ask "what exactly did *you* do?" at least twice, so answer with an artifact you wrote: the rules spec, the RAID log, the trace-ID proposal, the eval set.
Data-driven honesty	The basis word goes with every number: record, from the doc, my estimate, modeled. A Bar Raiser rewards "I don't know, and here is how I would find out" over a confident decimal.
Raising the bar	Would this person raise the average of the team? Show that standards were set *before* the pressure arrived (the 99% data gate, the <5% mismatch gate, the 98% pick bar), and that a control outlived the program.
Long-term thinking	Things I gave up in the short term for the long term: the engine waited for the data, the cheap path was proved on an eval set first, and the access review now sits on every kickoff checklist.
Self-awareness	A real failure, owned in the first sentence, with the root cause in my own process and a standing control that proves the lesson stuck.

How the three-level dig goes, and the pre-emptive line for each level

Level 1, "What exactly did YOU do?" Pre-empt it inside the Action: "I wrote… I ran… I decided…; engineering built…; Finance signed…". End the Action with one sentence that separates *mine* from *theirs*.

Level 2, "What was the data? How did you know?" Pre-empt it with the baseline number, the measurement grain and the source in the Situation: "three years of shipment history I pulled in SQL", "836 rows, March 2024 to October 2025".

Level 3a, "Who disagreed, and were they right?" Name a real dissenter and concede the part where they were right: the procurement team I brought in late, QA's fear of compressed testing, leadership pulling my engineers.

Level 3b, "What would you do differently?" One concrete change in my own process. It is never "communicate more". Examples: build the audit ledger during the pilot, version the eval set on day one, ship the quick-reference guide earlier.

Level 3c, "What happened after?" The control that outlived me: Finance reused the savings method, other regions adopted the tool without a mandate, the trace ID became the standard way to debug.

Pre-empt technique (say it once, early): "I'll tell you what I owned, what the team built, and the number with its source. Stop me where you want depth." After that, every answer runs Situation with baseline, Task with my scope, Action with my artifacts, Result with the number and its basis, then one line of what I'd do differently.

"I vs we" ledger — the five most attackable claims

CLAIM	WHAT WAS MINE	WHAT WAS THEIRS	SENTENCE IF HE PUSHES
About $8M validated freight savings (R1)	The SQL baseline, the rules-engine spec, the data gate, the savings method co-written with Finance, the pilot read	Carriers and the transportation team executed the tenders; Finance audited the claims; engineering built the engine	"The $8M is executed savings, counted per shipment by a method Finance co-owned before the first claim. I owned the method and the gate, not the freight contracts."
Time to fix blocker bugs down 50% (R5)	Noticed the missing ID while reading application logs in the bug bash; proposed the design change; defined the load-event tracing metric; ran the monitoring checklist	Engineering on the Visibility, Ocean and Flexport OS teams implemented the trace stories and the Datadog monitors	"I found it and proposed it; three teams built it. The 50% is from my one-pager, measured on blocker bugs."
Both programs landed in the compression (R6)	The RAID log, the 45-minute forum, the blocker ruler, escalations framed as priced decisions, the quick-reference guide	Shared engineers did the build and both war-room passes; the DC floor adopted	"Making the collision visible and survivable was mine; the code and the adoption were theirs."
Carrier-bid cycle 6 weeks → about 3 (R2)	The time audit, the lane-master spec, the constraint rules, the <5% gate, the parallel run	Transportation and procurement ran the award; engineering built the tool	"Cycle time is the number I own. I claim no award savings, because the award was theirs." (user anchor)
$25 → $0.40 per incident (R7)	All of it: the code, the eval set, the routing, the citation rule	Nobody else, because it was an independent build	"This one is mine end to end, which is why I tell it as a build story and not as a program story."

16-LP self-audit — my strongest evidence line, its number, and the soft spot I name first

LP	STRONGEST EVIDENCE LINE	NUMBER (BASIS)	SOFT SPOT TO NAME FIRST
Customer Obsession	R1: everyone asked for "fix the carriers", but the real need was "make lateness measurable"	DQ ~40% reported, ~55% true → 99% (record)	F1: I once defended with screenshots instead of reproducing the customer's experience
Ownership	R5: as TPM I read application logs in the bug bash and proposed a cross-team design change	MTTR −50% (record-from-docs)	F2: I discovered the security review instead of planning it (two weeks)
Invent & Simplify	R2: a reconciliation problem everyone called an optimization problem	6 weeks → ~3 (user anchor)	Procurement joined late, and that was my miss
Are Right, A Lot	R5: a production test account instead of staging, decided on pros and cons with product and engineering	300-container start (record-from-docs)	F3: my first in-transit rule was too conservative
Learn & Be Curious	R7: I learned LLM engineering by building an agent, not by reading	$25 → $0.40 (record)	The eval set was not versioned on day one
Hire & Develop	R9: the QA lead authored the definition of done; R3: site super-users own the mapping tables	4-week cadence in 6 weeks (record)	No large direct-report org, and I say so (Apple gap script)
Highest Standards	P3: the 98% pick bar, set before the robots arrived; R8: one log, one grammar	Week 2 at 94% → 30% throttled (record)	Should have put the monthly shape on the wall from month one
Think Big	R1: one Austria pilot became a method for 25 locations, and Finance reused it	~$8M across 25 European locations (record)	The audit-ledger format settled late
Bias for Action	R6: two programs on one ruler, decided inside week one	~$200K/month per DC at stake (record)	The team's calendar paid for the compression
Frugality	R7: cost engineered like a budget line, with accuracy held	−98% per incident (record)	At Amazon scale, the eval-set upkeep becomes a program of its own
Earn Trust	R4: one owner per work item between two orgs, written down and agreed	15 work items for 2023 (record-from-docs)	ISF filing stayed unresolved at the first meeting; my authorship is VERIFY
Dive Deep	R5: I created the load-event tracing metric	2–4 hrs to find a bug's source (record-from-docs)	Monitoring arrived later than it should have (Path to 4PL lesson)
Backbone	R6: I pushed for visibility, not against the decision, then committed	Landed inside 4 weeks (record)	I did not win the argument over engineers, and I say so
Deliver Results	P1: combined go-live with zero customer-facing incidents; P2: eight months, 3% under budget	+15% processing efficiency (record)	Training slipped 1.5 weeks on JDA (P7)
Earth's Best Employer	R6: a two-pass war room so nobody worked 24 hours; R9: QA's fear became the design	45-minute forum (record)	Thin. I don't stretch it into a DEI story I don't have
Broad Responsibility	R4: shared cost-to-serve goals across two orgs; F3: I changed a rule that was hurting customers	Oversell increase = zero (user anchor)	The in-transit rule starved dotcom for weeks before I fixed it

3 · More examples — nine additional full-STAR stories (R1–R9) NEW

None of these are P1–P7. Each story has a 60-second pitch, S/T/A/R, who I influenced, TRADE-OFF I MADE, a failure/learning line, LP tags, four probing Q&As, SAFE-SAY and a 20-second version. Program-leader framing throughout, with numbers in prose and their basis labels.

R1 · Austria first, then 25 European locations — the routing-guide engine waits for the data FREE

Company: Elementum (supply-chain SaaS), client logistics program · **My role:** program lead for the analysis, the rules design and the rollout gate · **Sources:** Apple v11 F2 p35–37; GFiber v8 S10 p120–121; master S10
Headline: about $8M validated freight savings across 25 European locations (record) · Austria pilot about $500K a year (record) · data quality ~40% reported / ~55% true → 99% within a quarter (record)

60-SECOND PITCH

"At Elementum, a client's transportation team in Austria could not measure on-time delivery. The report said data quality was 40%, the team spent eight to ten hours a week reconciling dates by hand, and everyone believed the carriers were late. I owned the analysis, the rules design and the rollout gate. I pulled three years of shipment history in SQL myself. True data quality was about 55%, and the problem was measurement, not carriers. I set one rule: the routing engine waits for the data. Nothing scales until quality hits 99%. I also wrote the savings method with Finance before anyone claimed a dollar: contracted rate against what would have been paid, per shipment, executed only. The Austria pilot went live inside a month, measured about 97% on-time accuracy and about $500K a year, and that green-lit 25 European locations. It closed at about eight million dollars of validated freight savings, and Finance reused the method afterwards."

S — Situation. The client's Austria site had a routing guide on paper and no enforceable on-time delivery (OTD). Reported inbound data quality was about 40%, and logistics spent 8–10 hours a week reconciling promised dates against actual dates (record, Apple F2). The site, the carriers' account teams and my own sponsor all believed the carriers were the problem. The freight base had no SLA anyone could hold a carrier to.

T — Task. I owned the analysis, the rules-engine design, the savings-validation method and the scale gate. Transportation, Finance and engineering did not report to me. The targets were set with the business: data quality to 99%, the manual reconciliation retired, and every savings dollar auditable.

A — Action.

- **Baseline first.** I pulled three years of shipment history in SQL and ran a defect census. The defects were missing contracted rates, lanes keyed at the wrong grain, carrier names in five spellings, and transit times copied from a brochure. True quality was ~55%, not 40%. I took the reframe to the sponsor: we are not measuring lateness yet.
- **Method before money.** I co-wrote the savings definition with Finance before the first claim: contracted guide rate minus counterfactual paid rate, per shipment, per lane, *executed* savings only, never "negotiated".
- **The gate.** The engine waits for the data. The quality gate was 99% before scale, tracked weekly by defect class, with each class owned and burned down on the same weekly read.
- **Rules written down before configuration.** Ship-from, ship-to, mode, volume, Incoterm and SLA. A lane with no match pages a human; it never falls back to a default carrier. Gaps after go-live surfaced as alerts with reason codes.
- **Pilot on the ugliest mix, then scale off the pilot's own numbers.** Austria went live inside one month. Super-users per region and a one-page runbook carried the rollout to 25 European locations (runbook and super-users:

user anchor, GFiber v8).

R — Result.

- About **$8M of validated freight savings across 25 European locations**. Every dollar is auditable back to a shipment (record, Apple F2 and resume).
- Data quality **~55% true → 99%**, "within a quarter" (record. Apple says two months, the master says about three, so the quarter is true under both).
- Austria pilot: **~97% on-time measurement accuracy and ~$500K a year at one site**. Those were the numbers that made the scale call (record).
- Manual reconciliation of **8–10 hours a week** retired (record). The "1–2 hours after" figure is a user anchor (GFiber v8), and I say it only if asked.
- Finance **reused the validation method** for the next claims, so the control outlived the program (record).

Who I influenced: the sponsor (from "carriers are late" to "we can't measure late"), using his own three years of data · Finance (co-owner of the savings definition before any claim) · transportation managers (from picking carriers to managing exceptions with reason codes) · regional super-users (they own the rules files).

TRADE-OFF I MADE

Options: (a) turn on the engine now and clean the data in flight, or (b) hold the engine until quality reached 99%. I chose (b). I rejected (a) because an engine fed dirty lanes tenders with confidence and gets it wrong, and one visibly wrong tender costs more trust than a month of delay. It cost a slower start and savings deferred by weeks, and the sponsor had to wait for the first dollar.

Failure / learning: The audit ledger's format settled while the first claims were already being made. I would build it during the Austria pilot, which would have made the first CFO review shorter.

Dive Deep — three years of history in SQL showed 55% true, not 40% reported.

Think Big — one site's pilot was built as the template for 25 locations.

Insist on the Highest Standards — the 99% gate held before scale.

Customer Obsession — the customer asked for "fix the carriers" when the need was "make late measurable".

PROBING — FOUR QUESTIONS HE WILL ASK

"$8M — how do you avoid double counting?"

Each saving is counted once, per shipment, as the contracted guide rate against the counterfactual paid rate, executed only. Double counting lives in programs that count "negotiated" and "executed" separately. Finance co-owned the definition before the first claim.

"What exactly did you do versus the engineers?"

I pulled the data and ran the census, wrote the rules spec and the gate, co-wrote the method, and read the pilot to make the scale call. Engineering built and configured the engine. The carriers' performance was the carriers'.

"Who disagreed?"

My sponsor and the site, at first. They wanted carrier penalties now. They were right that carriers had real misses, and the scorecard caught those later. They were wrong that we could prove it on 55%-quality data. The SQL census settled it, so I didn't have to argue.

"What happened after you left the program?"

Finance kept the validation method for the next claims, and the super-users kept the rules files. A new site cost one rules file and one data-quality cycle (user anchor). That is the mechanism, not me.

SAFE-SAY (most attackable number): "About eight million of validated freight savings across twenty-five European locations, counted per shipment, executed only, by a method Finance co-owned. That is the record figure, and I never say one million or a lane count."

"What's your source?" "My program record and resume: the Austria pilot read and the Finance-validated ledger."

20-SECOND VERSION

"Austria said carriers were late. Three years of data in SQL said we couldn't even measure late: 55% true quality, not 40%. I held the engine until data hit 99% and wrote the savings method with Finance first. The pilot was 97% accurate and worth about $500K a year, and the rollout to 25 European locations closed at about $8M validated."

R2 · The semi-annual carrier bid — a reconciliation problem everyone called an optimization problem FREE

Company: Elementum, client transportation team · **My role:** owned requirements, constraint rules, validation gate and parallel run, not the award · **Sources:** GFiber v8 S17 p166–167; master S17
Headline: bid cycle 6 weeks → ~3; pilot region 3 weeks early; adopted by other regions without a mandate (all **user anchor** — GFiber v8 only; no Apple or primary-doc support). No dollar claimed.

60-SECOND PITCH

"A client ran a carrier bid twice a year: hundreds of lanes, dozens of rate files, six weeks a cycle. Everyone assumed it was an optimization problem and wanted a better solver. Before building anything, I sat through one full bid cycle and logged where the hours went. Most of the six weeks was reconciliation, because every carrier named lanes and modes differently. So I specified a lane master, wrote the constraints as explicit rules, and set a gate: the tool had to match the last two real awards within 5% before anyone trusted its output. We parallel-ran it on one region's live bid. The cycle went from about six weeks to about three, the pilot region finished three weeks early, and other regions adopted it without a mandate. My miss: procurement joined late."

S — Situation. The client's transportation team ran a semi-annual carrier bid across hundreds of lanes and dozens of carrier rate files, with constraints like incumbency floors and volume commitments. Each cycle took about six weeks (user anchor). The team's working belief was "we need a better optimizer".

T — Task. I owned the requirements, the constraint rules and the parallel run. Transportation, procurement and engineering did not report to me, and the award itself was theirs.

A — Action.

- **Diagnose the problem class with a time audit.** I sat through a whole bid cycle logging hours by activity. The six weeks went to reconciling lane names and mode codes, not to analysis. I wrote a one-page problem-class memo: reconciliation, not optimization.
- **Simplify the input, not the solver.** A lane-master spec normalizing origin, destination and mode. Every constraint became one explicit, readable rule: volume commitments, incumbency floors, mode rules.
- **A trust gate before any output counted.** Less than 5% mismatch against the last two award cycles before the optimizer could run. Scenario comparison was a first-class output, and I rejected a black box in writing.
- **Parallel run on a live bid.** One regional team's real bid ran on both paths.
- **Keep it honest after cutover.** Weekly rate-file refresh, with a stale-data banner after 10 days.

R — Result.

- Bid cycle **about six weeks → about three** (user anchor). The pilot region finished **three weeks early** (user anchor).
- Other regions **adopted it without a mandate** (user anchor).
- **No award dollar claimed.** The award belonged to transportation and procurement. Any dollar figure for analyst time returned is modeled only, and I don't lead with it.

Who I influenced: transportation leadership (from "buy a better solver" to "fix the lane names", using their own hours) · the regional team that volunteered the parallel run · engineering (scenario comparison instead of a black box) · procurement, late, and that is the miss.

TRADE-OFF I MADE

Options: (a) build or buy a stronger optimizer, which everyone expected, or (b) fix reconciliation first and keep the solver simple and explainable. I chose (b). I rejected (a) because a better solver on mismatched lane names gives a faster wrong answer. It cost one full bid cycle of observation before any build, and some impatience from a team that wanted a tool.

Failure / learning: Procurement joined late. They owned award rules I had to retrofit. Lesson: put every owner of a constraint in the room at discovery, not at design review.

Invent & Simplify — the usual approach (a better solver) wouldn't address it; a lane master would.

Dive Deep — a time audit across one full cycle, before any design.

Have Backbone — I said "it's not an optimization problem" to a team that had already decided it was.

Deliver Results — about half the cycle time, with the pilot three weeks early.

PROBING — FOUR QUESTIONS HE WILL ASK

"How do you know the time saved wasn't just a quieter cycle?"

The same team on the same kind of bid, measured against my own time audit of the previous cycle. The honest caveat: those counts are my anchors from the program and not an audited report, so I say "about half".

"Why a 5% gate?"

It had to beat a planner's gut on the last two awards they already trusted. Below 5% mismatch, the planners trusted the tool enough to stop re-keying. Above it, they would have kept running the old spreadsheet beside it.

"Who disagreed, and were they right?"

Procurement, when they arrived. They were right that two award rules weren't in my constraint set, so I added them as explicit rules before the second region.

"What would you do differently?"

Bring procurement in at the time audit. I'd also publish the stale-data banner rule from day one, not after the first stale week.

SAFE-SAY: "About six weeks to about three. Those are my program anchors, and I claim no award savings because the award belonged to transportation and procurement."

"What's your source?" "My own time audit of the bid cycle and the program record. There's no published report, so I give you the shape and the gate."

20-SECOND VERSION

"Everyone wanted a better carrier-bid optimizer. I sat through a full cycle and found the six weeks were reconciliation, not optimization. I built a lane master, wrote the constraints as rules and set a 5% match gate, and the cycle went to about three weeks. My miss was bringing procurement in late."

R3 · Six sites, three waves — a contract manufacturer's data rolled out site by site, with reconciliation as the go-live gate FREE

Company: Elementum, client manufacturing program with an external contract manufacturer · **My role:** owned ingest requirements, the reconciliation gate and the wave plan, and was the person on the weekly call with the contract manufacturer · **Sources:** GFiber v8 S7 p93; master S7 (told here at site grain)
Headline: 0 → 6 sites with planning-grade supply visibility in three waves over about five months; hardest site took 6 weeks against a 3-week average and was absorbed in the plan; zero overlapping revisions auto-loaded (all **user anchor** — GFiber v8 only). No dollar claimed.

60-SECOND PITCH

"At Elementum, a client's supply visibility depended on data from an external contract manufacturer across six site systems. The six sites had six different definitions of yield, lead time and order status. I owned the ingest requirements, the go-live gate and the wave plan. I sequenced it like a deployment. Wave one was the two cleanest high-volume sites, to prove the pattern. Wave two was three sites on parameterized maps. Wave three was the hostile one: a legacy system with flat files and no change-data-capture. The rule: no site goes live until its reconciliation report matches the source. Overlapping revisions went to a quarantine queue for a human to decide, and were never auto-loaded. A named super-user at each site owned the mapping tables. Six sites went live in three waves over about five months. The hostile site took six weeks against a three-week average, and that was absorbed in the plan because I had sequenced it last."

S — Situation. The client's supply view depended on data an external contract manufacturer published from six site systems. The six systems carried six definitions of yield, lead time and order status. Two revisions of the same data could be partly valid at the same time for weeks, so auto-loading one would silently rewrite history. One site ran a legacy system with flat-file exports and no change-data-capture (user anchor).

T — Task. I owned the ingest requirements, the per-site reconciliation gate, the wave plan and the weekly call with the contract manufacturer. Their engineers, our data engineers and the client's planners did not report to me.

A — Action.

- **Catalogue before you map.** I built a six-site definition inventory (yield, lead time, order status) and a discovery memo naming the traps, and I had the contract manufacturer's engineering confirm it.
- **Wave by risk, not by geography.** Wave 1 was the two cleanest high-volume sites. Wave 2 was three sites on parameterized maps. Wave 3 was the hostile legacy system, scheduled last with buffer.
- **A gate that can stop a site.** A site went live only when its reconciliation report matched the source within tolerance. The tolerance value is not in my record, so I don't quote one.
- **Quarantine, never auto-load.** Overlapping revisions went to an effective-date quarantine queue for human disposition.
- **Engineer around the hostile system.** With no change-data-capture, we used snapshot-diffing on the flat files instead of waiting for an upgrade the site couldn't fund.
- **Hand ownership to the sites.** A named super-user at each site owned that site's mapping tables. The weekly call with the contract manufacturer became standing, framed as their protection, not our audit.

R — Result.

- **0 → 6 sites** with planning-grade supply visibility, in **three waves over about five months** (user anchor).
- **Hardest site 6 weeks vs a 3-week average**, absorbed because it was planned last with buffer (user anchor).
- **Zero overlapping revisions auto-loaded** (user anchor). This data backbone is what the later lead-time program ran on.

- No dollar claimed. Anything priced here would be modeled, and I don't lead with it.

Who I influenced: the contract manufacturer's engineering (confirm our reading of their data; the weekly call as their protection) · six site leads (each named a super-user to own the maps) · our data engineers (snapshot-diffing instead of waiting for change-data-capture) · the client's planners (no site counted until it reconciled).

TRADE-OFF I MADE

Options: (a) a big-bang load of all six sites on one generic map, or (b) three waves with per-site reconciliation gates. I chose (b). I rejected (a) because one bad site would have poisoned trust in all six. It cost about five months instead of a faster single cutover, and the hostile site's six weeks had to be carried openly.

Failure / learning: I learned to reconcile to the source's actual data, not its documentation. The documentation was not the truth; the source system's own numbers were. Next time I'd run the reconciliation report on a sample before writing the mapping spec, not after.

Deliver Results — six sites in three waves; the obstacle (no change-data-capture) was planned for, not discovered.

Frugality — snapshot-diffing instead of funding a legacy upgrade.

Hire & Develop the Best — site super-users own their maps; the capability lives at the site.

Insist on the Highest Standards — no site live until it reconciled.

PROBING — FOUR QUESTIONS HE WILL ASK

"What was the tolerance on the reconciliation gate?"

It isn't in my record, so I won't give you a number. The design was a per-site report that compared our loaded view against the contract manufacturer's own system for the same items and dates, and the site waited until it matched.

"Why not make the legacy site upgrade?"

No budget and no timeline. Snapshot-diffing the flat files gave us change detection without asking them to fund anything. It cost three extra weeks, which the plan already carried.

"What did you personally do on that hostile site?"

I sequenced it last, wrote the requirement for snapshot-diffing, and ran the weekly call where its reconciliation was read. Data engineering built the diff.

"What happened after?"

The super-users kept the maps, the weekly call stayed standing, and the lead-time distribution work (told elsewhere) ran on this backbone.

SAFE-SAY: "Six sites in three waves over about five months. Those are my program anchors, and I give no dollar figure because the record holds none."

"What's your source?" "My program record of the wave plan. The counts come from me, not from a published report."

20-SECOND VERSION

"An external manufacturer's data across six site systems, six definitions of the same fields. I rolled it out in three waves by risk, with reconciliation as the go-live gate and super-users owning each site's maps. Six sites in about five months, and the hostile site's extra three weeks were already in the plan."

R4 · One owner per work item — the Customs Platform ↔ FF App ownership split FREE

Company: Flexport, 2022, Freight Forwarding App (FFA) export program · **My role:** FF App-side program lead on the ownership split VERIFY: role and authorship — my name is not on either meeting note's attendee list · **Source:** Customs_Platform_Ownership_Proposal p1–14 (meeting notes Oct 26 and Nov 3, 2022)
Headline: 15 work items planned for 2023 (12 export, 3 import) (record-from-docs) · agreement on Nov 3, 2022: FFA owns all export work items except ISF filing; AMS and AES through Customs Platform APIs; shared cost-to-serve goals (record-from-docs).

60-SECOND PITCH

"At Flexport in 2022, two tech orgs, Customs Platform and the Freight Forwarding App, were both building pieces of export customs. 2023 had fifteen work items on the plan, twelve export and three import, and nobody could say who owned which. That meant duplicate builds and two teams blocking each other. I took it as a design problem, not a turf fight. Customs owns customs planning and execution; the forwarding app owns the operational work of moving cargo onto a vessel. I put every work item in one table with its user group, whether it already existed in core, the proposed owner and the open question, and we worked it row by row in two sessions. By November 3rd: the app owns every export work item except ISF filing; AMS and AES go through Customs Platform APIs; and both teams share the cost-to-serve goal. The split was in writing before a line of 2023 code."

S — Situation. In 2022 the Customs Platform and FFA tech orgs overlapped on customs declaration work, especially the AMS (automated manifest) work item. The 2023 plan held **15 work items: 12 export and 3 import** (record-from-docs, p1). With no owner per item, there was a risk of duplicate builds, cross-team blocking and fuzzy accountability for cost-to-serve.

T — Task. Get one named owner per work item, agreed by both orgs, before 2023 build planning. Neither org reported to the other, and neither reported to me.

A — Action.

- **A principle first, then the rows.** Customs Platform focuses on customs planning and execution. FFA focuses on the operational execution of moving cargo onto a vessel, including the backend services, data models and automation for its own items.
- **One table, every work item.** Columns: work item, user group, description, exists in core?, proposed owner, notes, engineering conclusion. Upload SLI, File AES, Request/Generate/Upload EAD, portfiling, China export documents, ISF worksheet and filing, AMS.
- **Decide on qualification, not preference.** Only licensed brokers can file AES and ISF, so those stayed with customs or used its APIs. Portfiling is a seaport requirement tied to the EAD, so it sat with operations.
- **Integration contracts instead of shared code.** AMS: Customs Platform exposes atomic APIs (create, amend, query, delete). FFA collects the filing data and monitors for changes that need a re-file. Customs translates disposition codes and broadcasts status.
- **Write down the "not now".** EAD stays offline with external brokers until customs can integrate with them. China customs documents may be revisited in 2025. Import items come next, API-only.

R — Result.

- Final export agreement on **Nov 3, 2022**: **FFA owns all export work items except ISF filing** (record-from-docs, p14).
- **AMS and AES through Customs Platform APIs**, so integration replaced duplicate builds. Customs Tech and FFA **share cost-to-serve goals** on AMS (record-from-docs).

- Deferred items carried in writing with a trigger: EAD integration when customs can reach brokers; China customs in 2025; import items next.

Who I influenced: the Customs Platform engineering lead (agreed ownership of AES and ISF filing, subject to his business team, and preferred API-only integration) · Customs Tech's business owners (where each filing item lives) · FFA engineering (owns the operational items end to end) · the operations leads who had been doing EAD and portfiling by email.

TRADE-OFF I MADE

Options: (a) push every customs-adjacent item to Customs Platform, which is cleaner on paper; (b) build everything inside FFA, which is faster for us; or (c) split by qualification and operational ownership, with APIs at the seams. I chose (c). I rejected (a) because Customs had no plan to integrate with external brokers, so items would sit unowned. I rejected (b) because it would have duplicated licensed filing logic. It cost leaving ISF and AES unresolved through the first session and carrying EAD offline for now.

Failure / learning: The first session ended with two items, AES and ISF filing, still open, because the right business owner wasn't in the room. Lesson: get the business owner of every regulated item into session one, not just the engineering lead.

Earn Trust — two teams with misaligned goals left with one table both signed off on.

Invent & Simplify — one owner per row, with APIs at the seams instead of shared code.

Success & Scale Bring Broad Responsibility — cost-to-serve became a shared goal, not one team's metric.

Ownership — an un-owned overlap, picked up and closed.

PROBING — FOUR QUESTIONS HE WILL ASK

"Was this your document?"

I was on the FF App side of the split and worked the rows with Customs Platform engineering VERIFY. The attendee lists on both meeting notes don't include me, so confirm my exact role before telling this. If I wasn't in the work, drop R4 and use R2 instead. If he presses on authorship: "I'll be precise. The document and the meeting notes record the agreement, and my role was the FF App program side of it."

"Who disagreed?"

On AES and ISF filing, Customs engineering was willing to own them but needed their business team to decide where the item lived, and preferred API-only integration if it stayed in FFA. They were right that a licensed filing shouldn't be rebuilt outside customs, so we took the API route.

"How did you measure success?"

Every 2023 export item had one owner and one integration contract before build planning. The honest gap: the document records the agreement, not a later delivery metric, so I don't claim a downstream number.

"What would you do differently?"

Start with the import items in parallel. They followed later, and the same table would have taken one more session.

SAFE-SAY: "Fifteen work items on the 2023 plan, twelve export and three import. The agreement was written on November 3rd, 2022: the app owns every export item except ISF filing."

"What's your source?" "The ownership proposal and its two sets of meeting notes, October 26 and November 3, 2022."

20-SECOND VERSION

"Two tech orgs at Flexport were both building export customs, with fifteen work items for 2023 and no owners. I split it by principle: customs owns filing, the forwarding app owns moving the cargo. We worked one table row by row, with APIs at the seams. In two sessions, every export item had an owner except ISF, and both teams shared the cost-to-serve goal."

R5 · One trace ID through six systems — observability and incident response on a nine-team platform SV FAMILY — DIFFERENT ANGLE

Company: Flexport, Shipment Visibility (SV) launch and the 3PL ingestion test, 2021–22 · **My role:** TPM for the SV initiative across 6 systems and 9 teams · **Sources:** Shipment_Visibility_3PL_ingestion One-Pager p1–8; State_of_SV_E2E_Connectivity_Monitoring p1–8; Path_to_4PL p1–2; TPM status 11/19/21 p2, p10
Headline: blocker-bug MTTR −50%; troubleshooting had taken 2–4 hours just to find the system holding the bug (record-from-docs). **Not the wave/CTS story the HM heard**: this is the infrastructure layer underneath it.

60-SECOND PITCH

"At Flexport I was the TPM on Shipment Visibility: six systems, nine teams, close to a hundred people. In the bug bash I was reading application logs alongside the engineers, and I noticed there was no unique ID tying an event as it flowed from the downstream systems up to the customer screen. Every blocker took two to four hours just to find which system the bug lived in, before anyone could fix it. I recommended a design change: one traceable load-event ID end to end, plus a metric at every hop, events arriving divided by events sent, and events dropped divided by events planned. I wrote it up, got the engineering managers on Visibility, Ocean and Flexport OS to slot the stories, and paired it with Datadog monitors on every connectivity point and a list of kill switches before any production test. Time to fix a blocker bug fell by half. The lesson I wrote into our retrospective: monitoring should have come earlier in the lifecycle."

S — Situation. SV launched in December 2021 on new infrastructure integrated into the Flexport platform. **9 teams, close to 100 people** (Path to 4PL p1). Data travelled through **six or more system layers**, many too new to have robust monitoring. During testing, finding where a bug manifested took **2–4 hours** before an engineer could start fixing it (one-pager p1; Path to 4PL p2).

T — Task. As TPM I was responsible for delivering SV across the 6 systems and 9 teams and for running the bug bash across engineering and product. No engineer reported to me.

A — Action.

- **Read the logs myself.** In the bug bash I triaged in the application logs with the team and found the gap: no unique ID tying events from downstream to the user-facing interface.
- **Propose the design change with a metric.** A unique, traceable load-event ID through Visibility → Ocean → Flexport OS → Client App, and a load-event tracing metric at each hop: *events in originating system ÷ events in destination system* and *events dropped ÷ events planned*.
- **Get it slotted across teams.** Trace stories were on track on the Visibility and Ocean teams, and the design doc was completed for Flexport OS (one-pager p3).
- **Monitors before customers.** A Datadog monitor and dashboard for every connectivity point (tracking-request submission, forwarding stream blockage and P95 event age, gRPC subscriptions, Kinesis producer errors, API latency and availability) so we were customer-ready on 11/19 (E2E monitoring doc p1–8).
- **Blast-radius control for the next test.** For the 3PL ingestion test I listed the switches to turn off (for example the Ocean subscription kill switch and the trade-graph extract switches), restricted testing to named client and trade-lane combinations, and reused the holiday support framework for blocker and critical issues (one-pager p5–6).

R — Result.

- **Blocker-bug MTTR −50%** after the trace-ID design change (record-from-docs, the one-pager's own result line).
- Every SV connectivity point had a named monitor in production before the customer-ready date (record-from-docs). Performance tests completed and testing moved from staging to production (TPM status 11/19/21).

- The 3PL test plan made load-event tracing the success metric and excluded performance and cost-to-serve on purpose (one-pager p2).

Who I influenced: the engineering managers on Visibility, Ocean and Flexport OS (three backlogs carried a story none of them owned alone) · product (prioritize engineering-found issues; spot-check 10% of shipments) · the DRI and business leadership (keep the test to named clients and lanes).

TRADE-OFF I MADE

Options: (a) keep fixing bugs as they came, which is faster this week, or (b) spend sprint capacity on a cross-system trace ID and monitors that no customer would see. I chose (b). I rejected (a) because at 2–4 hours per bug just to locate it, the bug bash would never converge across six layers. It cost feature capacity on three teams during a delayed pilot.

Failure / learning: Our own retrospective says it: internal system monitoring came too late in the lifecycle, and test-effort estimates were too optimistic (Path to 4PL p2). On any new platform, I now put the trace ID and the monitors in the first sprint, not the bug bash.

Ownership — a TPM reading application logs and proposing an architecture change outside his remit.

Dive Deep — created the load-event tracing metric that made drops visible per hop.

Are Right, A Lot — brought engineering, product and three teams' perspectives into one design.

Bias for Action — the production test account decision (see New-since-this-morning, N4).

PROBING — FOUR QUESTIONS HE WILL ASK

"MTTR down 50% — measured how?"

On blocker bugs, comparing the troubleshooting time before and after the trace ID. That's the result line in my own one-pager. The before was 2–4 hours just to locate the system. I don't have a per-bug distribution in the doc, so I say "about half".

"Why was a TPM in the application logs?"

Because the bug bash was stalling and I was the only person looking across all six systems at once. Each engineer saw their own hop, and nobody saw the seam.

"Who pushed back?"

An engineering manager pointed out that the downstream system couldn't carry the ID yet. That was right, so it went in as a dependency with its own story and design doc rather than a hack.

"What would you build first at Amazon Infrastructure?"

The trace and the hop-level drop ratio before the first integration test, and monitors per connectivity point owned by the team that owns the hop. Then a kill-switch list per launch, reviewed at go/no-go.

SAFE-SAY: "Time to fix blocker bugs fell by about half after the trace-ID change. That's the result I recorded in my own one-pager at the time."

"What's your source?" "The SV 3PL-ingestion one-pager and the E2E connectivity-monitoring doc. The 'monitoring came late' lesson is in the 2021 Path-to-4PL review."

20-SECOND VERSION

"Six systems, nine teams, and no ID tied an event to its source, so each blocker took two to four hours to locate. I proposed one trace ID end to end with a drop ratio at every hop, got three teams to build it, and put a Datadog monitor on every connectivity point. Time to fix a blocker bug fell by half."

R6 · Two programs, one team, one ruler — the compressed go-live FREE

FF APP FAMILY — DIFFERENT ANGLE

Company: Flexport, 2022 · **My role:** program lead running my own program while a strategic go-live was pulled forward onto my shared engineers · **Source:** Apple v11 B3 p20–21 (dossier PM-4; 2022 onsite Senior TPM / Ambiguity doc)
Headline: go-live pulled forward a month; ~$200K a month per DC of savings at stake (record) → compressed program landed inside four weeks, mine on its original date; about $1M per DC protected (cumulative framing, record — quote the rate first).

60-SECOND PITCH

"At Flexport in 2022, leadership pulled a strategic go-live forward by a month and shared my engineering team across both programs. Two programs, one team, an immovable date, and about two hundred thousand dollars a month per DC of savings at stake. Arguing priority would have wasted the month. Instead I ran both as one system: one RAID log, one forty-five-minute daily forum, and one ruler for every issue. Is it a true blocker, a non-blocker, or a requirements gap pretending to be a blocker? Within a week most 'blockers' were reclassified. The true ones went to a two-pass war room, onsite then offshore with a written handoff, so work moved around the clock without anyone working twenty-four hours. Go/no-go read the blocker burn-down against an agreed floor, not the calendar. The compressed program landed inside four weeks, mine held its original date, and the business adopted on time."

S — Situation. Leadership pulled a strategic go-live forward one month and shared my engineers across both programs. About **$200K a month per DC** of savings was at stake (record). The metric in danger was on-time business adoption: a compressed landing the floor rejects is a miss that compounds.

T — Task. Land both programs without sacrificing the floor's adoption, with half a team, no new headcount and a date I didn't set.

A — Action.

- **One system for two programs.** One RAID log (issue, class, owner, date, program) and one 45-minute daily forum that ruled on both.
- **One ruler.** True blocker, non-blocker, or requirements gap in disguise. Most "blockers" were reclassified within about a week, so engineering stopped context-switching on non-bugs.
- **Two-pass war room.** Onsite pass, then offshore pass, with a written handoff: issues moved around the clock and nobody worked 24 hours.
- **The floor, not the calendar.** Go/no-go read the true-blocker burn-down against a floor agreed in advance.
- **Escalations as priced decisions.** "A costs this, B costs that", raised the same day, never as complaints.
- **Protect the floor.** A ten-step quick-reference guide for the DC users before cutover.

R — Result.

- **Both programs landed**: the compressed one inside four weeks, mine on its original date (record).
- The business **adopted on time**, protecting **about $1M per DC** of savings that would have slipped into the next year (record. This is the cumulative framing of the ~$200K/month rate, and I quote the rate first).
- Nothing public slipped. The cost was the team's calendar, and I said so.

Who I influenced: leadership (escalations framed as priced choices, so decisions came the same day) · the shared engineers (one ruler, one forum, so they stopped serving two masters) · the offshore team (written handoff instead of overlap hours) · the DC floor (the quick-reference guide).

TRADE-OFF I MADE

Options: (a) fight the pull-forward to protect my program, (b) let my program slip quietly, or (c) accept the decision and make the collision visible on one ruler. I chose (c). I rejected (a) because once the pull-forward was priced it was probably right, and (b) because a hidden slip is found in week two. It cost the team's calendar: two war-room passes a day for weeks. I guarded the 45-minute forum hard so the load didn't grow.

Failure / learning: The ten-step quick-reference guide went out the week before cutover, but floor questions had been arriving for weeks. Under compression, documentation dies first. The guide was cheap, and I made it late.

Bias for Action — the ruler and the forum were running inside week one.

Have Backbone; Disagree & Commit — I pushed for visibility, not against the decision, then committed fully.

Frugality — two programs landed on one shared team with no added headcount.

Strive to be Earth's Best Employer — round-the-clock velocity without anyone working round the clock.

PROBING — FOUR QUESTIONS HE WILL ASK

"$200K a month becomes $1M per DC — over what window?"

The monthly rate is the number I'd defend cold: priced savings per DC per month in the program doc. The million is the cumulative protection framing from the same document. Pressed, I quote the rate and the sub-four-week landing.

"Isn't 'blocker, non-blocker, gap' just relabeling while things burn?"

It's triage. The proof is the count: true blockers burned down to the agreed floor, and go-live read the floor.

"Did you fight losing the engineers?"

I pushed for the cost to be visible, not against the decision. Disagree-and-commit is only real if the disagreement was visible first.

"What did you do versus the team?"

I ran the system: the log, the forum, the ruler, the escalation framing, the guide. The engineers built and ran both war-room passes, and the floor adopted.

SAFE-SAY: "About two hundred thousand dollars a month per DC was at stake. The compressed program landed inside four weeks, and mine held its date."

"What's your source?" "The 2022 program doc and my Senior TPM write-up of that quarter."

20-SECOND VERSION

"Leadership pulled a go-live forward a month onto my shared engineers. I didn't argue priority. I put both programs on one RAID log, one 45-minute forum and one blocker ruler, with a two-pass onsite-offshore war room. Both landed: the compressed one inside four weeks, mine on its date."

R7 · The LLM triage agent — $25 to $0.40 an incident, on an eval set and a citation rule

FREE

Context: independent build (not an employer program), recent · **My role:** everything: Python, FastAPI, LLM tool use, SQLite, the eval set, the cost engineering · **Source:** Apple v11 I1 p41–43; resume (LLM triage agent) **Headline:** cost per triaged incident $25 → $0.40 (−98%) with accuracy held on the eval set; citation coverage 100% (record).

60-SECOND PITCH

"I built an LLM triage agent for operational incident queues with my own hands. It reads the ticket, classifies it and proposes the first action with citations. The naive version worked, but it cost twenty-five dollars an incident. That's a demo, not an operations tool. I ran it like a program with a budget line. First, an eval set before the agent: graded historical incidents with known-correct outcomes, and every prompt, model or routing change had to keep the past passing. Second, a cost bar of under a dollar an incident, reviewed on every change. Third, one rule: no citation, no proposal. Every proposed action cites the ticket evidence and the runbook line. Then I routed the easy classes to small models and saved the expensive calls for the hard tail. Cost fell from twenty-five dollars to forty cents, a 98% cut, with accuracy held and citations at 100%."

S — Situation. Operational incident queues need a first triage: read, classify, propose the first action. A straightforward LLM agent did it at about **$25 per incident** (record), which is too expensive and too untraceable to put in front of an operator.

T — Task. My own build, end to end. Targets: triage accuracy held on known cases, citation coverage on every proposal, and cost per incident under $1.

A — Action.

- **Eval set before the agent.** Historical incidents with the triage outcome the organization already agreed was right: graded, versioned and growing. The contract was "change anything, but the past must keep passing".
- **Cost as a budget line.** The bar was under $1 per incident, reviewed on every change like a program budget.
- **No citation, no proposal.** Every proposed action binds to ticket evidence and a runbook line, so a human can check it in seconds.
- **Routing, not heroics.** A cheap classifier routes easy classes to small models, and expensive calls are reserved for the hard tail. The eval set proved the cheap path held accuracy before traffic moved.
- **One pane.** Triage accuracy on the eval set, citation coverage and cost per incident, the same three numbers every review.

R — Result.

- Cost per triaged incident **$25 → $0.40, −98%**, with accuracy held on the eval set (record).
- **Citation coverage 100%**: the agent never proposed without evidence (record).
- Beat the sub-$1 bar. The eval-set discipline is what I'd bring to any AI-in-operations program.

Who I influenced: nobody reported to me, and this is a build story, not an org story. The influence is downstream: the eval set and citation rule are the contract I'd hand an operations team before they trust an agent's proposal.

TRADE-OFF I MADE

Options: (a) one strong model for everything, which is simplest and most accurate per call, or (b) tiered routing with an eval gate. I chose (b). I rejected (a) because at $25 an incident nobody would run it at volume. It cost building and maintaining the eval set first, which was slower to start and a standing upkeep cost.

Failure / learning: I didn't version the eval set on day one. Early prompt changes were judged on a set that was still growing, so the first accuracy claims leaned on a moving baseline. Now I freeze version one first.

Frugality — −98% cost per incident, engineered like a budget line, quality held.

Invent & Simplify — routing plus one rule (no citation, no proposal) instead of a bigger model.

Learn & Be Curious — learned LLM engineering by building, not reading.

Insist on the Highest Standards — the past must keep passing before a change touches the present.

PROBING — FOUR QUESTIONS HE WILL ASK

"How did cost drop 98% without dropping quality?"

Mostly routing. Most incidents are easy, and a small model classifies them fine. The eval set made it safe, because I proved the cheap path on the easy classes before routing traffic there.

"Where would this break at Amazon's scale?"

The volume economics and the data-sensitivity review. Eval-set maintenance becomes a program of its own, and incident data carries customer content that needs an access review. That's my security-review scar (F2), and I'd schedule it at kickoff.

"Isn't this a side project?"

It's an independent build, and I say so. I tell it because it shows the same mechanism as my programs: a baseline, a gate, a budget line and a single pane, applied to AI.

"What's the eval set, concretely?"

Graded historical incidents with the agreed-correct triage, versioned, and every change runs against it first. It's the contract.

SAFE-SAY: "Twenty-five dollars to forty cents per triaged incident, about 98% lower, on my own independent build, with accuracy held on a graded eval set."

"What's your source?" "My own build and its eval and cost logs. It's on my resume as the LLM triage agent."

20-SECOND VERSION

"I built an LLM triage agent myself. The naive version cost twenty-five dollars an incident. With an eval set first, a no-citation-no-proposal rule, and small models routed to the easy classes, it runs at forty cents, 98% lower, with accuracy held and 100% citations."

R8 · One log, one grammar — turning an 836-row issues log into the go-live gate

P1 — DIFFERENT ANGLE (THE MECHANISM, NOT THE LAUNCH)

Company: Sephora, UDC dual-inventory conversion, 2024–25 · **My role:** program lead; I owned the instruments: the consolidated issues log and the coupled build plan · **Sources:** Apple v11 C2 p23–25; UDC_Consolidated_Issues_Log (pandas, 836 rows); NUMBERS-RECON canon #44–46, #52
Headline: 836 rows over 2024-03-17 → 2025-10-01; 714 closed = 85.4%; post-cutover spike of 271 rows (June 2025) burned down 65 → 21 → 14 → 4; zero customer-facing incidents (record). **Tell only if P1 has not already been told in full**. The angle is "a mechanism I built", not "the launch".

60-SECOND PITCH

"On the UDC conversion at Sephora there were about thirty build tracks and sixty-plus stakeholders. Status by opinion would have drowned us. So I built one instrument: one consolidated issues log with one grammar. Every row had a status, priority, operation, functional area, owner and date, and there were no side lists. The weekly review read blocker and critical rows first, and every red had a name and a date. Then I made the log the go-live gate itself: both go-lives read burn-down curves, not confidence. Over 836 rows, only about one in seven was actually a bug. The rest were requirements, action items, questions and parked decisions, so the log was the program's work-triage system, not a defect list. After the combined go-live the log spiked to 271 rows in a month and burned down 65, 21, 14, 4. That's a building healing, not a design problem. 85% closed, zero customer-facing incidents."

S — Situation. A live Utah fulfillment center was converting from two systemic warehouses into one omni facility. That meant **about thirty build tracks**, **60-plus stakeholders** and about a dozen systems (record). The at-risk read was go-live readiness: defect burn-down, track completion and cutover preparedness.

T — Task. Build the instruments so a surprise surfaced in a Monday review, not in cutover week, and make readiness a count rather than a feeling.

A — Action.

- **One log, one grammar.** Status ladder, priority scale, operation, functional area, owner, date. One row per issue. Dedupe was part of the rhythm.
- **Read the dangerous half first.** Blocker 164 + Critical 277 = 441 rows = 52.8% of the book (record). Those rows led every weekly review.
- **A parking-lot status that means "decided not now".** Written down with an owner and never silently deleted, so deferral was a decision, not drift.
- **The log is the gate.** Both go-lives (PO creation January 2025, combined May 2025) read burn-down curves against the bar (record).
- **Owner split as a resourcing signal.** IT/WMS 342, Ops 111, Locus-side 86. When an owner's queue grew two weeks running, I opened a resourcing conversation with the evidence attached.

R — Result.

- **836 rows, 714 closed = 85.4%**, with the open tail visible and owned (record, recomputed from the log).
- Type mix: **bugs 115 (~14%)**, requirements 159, action items 117, questions 23. It worked as a triage system, not a defect fire (record).
- June 2025 spike of **271 → 65 → 21 → 14 → 4**: a healthy cutover decay (record).
- **Zero customer-facing incidents** at both go-lives (record).

Who I influenced: about fifteen functions and the vendors (Blue Yonder WMS, Locus) to write into one log in one grammar · the IT/WMS lead (queue-growth evidence became a resourcing ask) · the steering committee (read the

curve, not the RAG color).

TRADE-OFF I MADE

Options: (a) let each track keep its own tracker, which is lighter for them, or (b) one log with enforced grammar and a weekly dedupe. I chose (b). I rejected (a) because two trackers mean two truths and blockers hide in the gap. It cost overhead on every track lead each week, and some friction from vendors used to their own tools.

Failure / learning: I'd put the monthly-shape view (ramp, spike, burn-down) on the wall from the first hundred rows. The counts were always there, but the arc was a manual read well into the program.

Insist on the Highest Standards — readiness came from counted rows against a zero-incident bar, twice.

Think Big — the log was redesigned from defect list into the program's operating system.

Dive Deep — only 14% bugs, and the owner split told the integration story.

Ownership — the instruments were mine; nobody else owned "the truth on Monday".

PROBING — FOUR QUESTIONS HE WILL ASK

"836 issues — wasn't that a fire?"

No, and the log itself shows it: 115 bugs, about one in seven. The rest were requirements, action items, questions and parked decisions. Every "should we?" got a row instead of a hallway conversation.

"How do you tell healing from a design problem?"

The shape. A spike with fast decay, 271 then 65, 21, 14, 4, is a healthy cutover. A spike that plateaus is a design problem.

"What did the vendors think of your grammar?"

Locus had its own tracker. Their rows came into the log with the same fields, 86 of 836, about a tenth, which made the robotics workstream's noise measurable inside a WMS conversion.

"Where did the plan slip?"

Locus retail testing slipped three weeks. It was re-slotted openly in the plan's revision sheet, not absorbed into weekends. That's failure F4.

SAFE-SAY: "836 rows from March 2024 to October 2025, 85.4% closed, about one in seven a bug, and zero customer-facing incidents at both go-lives."

"What's your source?" "The UDC consolidated issues log itself. I recomputed the counts from the export."

20-SECOND VERSION

"On a thirty-track warehouse conversion I built one issues log with one grammar and made it the go-live gate. 836 rows, only one in seven a bug, 85% closed. The post-cutover spike of 271 burned down 65, 21, 14, 4, with zero customer-facing incidents."

R9 · The QA lead who wrote the gate — growing owners in a 20-person team with no mandate

ALSO WITH JOSYULA — DIFFERENT ANGLE

Company: Sephora, JDA years, soon after I joined · **My role:** VP-sponsored lead for converting a 20-person product, engineering and QA team to agile delivery, with no line authority · **Source:** Apple v11 D3 p31–32; resume; master S15
Headline: six-week hybrid → four-week cadence in six weeks; critical defects −50%; copied by neighbouring teams (record). **Angle for Rocky: Hire & Develop / Earth's Best Employer.** The people I grew into owners. Josyula's telling is the influence-without-authority angle.

60-SECOND PITCH

"When I joined Sephora, the VP of supply chain asked me to move a twenty-person product, engineering and QA team from a six-week hybrid model to a four-week agile cadence. I had sponsorship but no mandate, and the team assumed four weeks just meant more work in less time. QA was the most afraid, because they expected their testing window to be crushed. Instead of designing around QA, I made the QA lead the author of the definition of done, with entry criteria. Their biggest fear became the design, and the QA lead owned the gate in front of the whole team. I ran one-on-ones across all three functions first, named an influencer in each, and published one chart every cycle showing what moved and what didn't. In six weeks we were on a four-week cadence, critical defects fell by half, and neighbouring teams copied it without being asked."

S — Situation. The team kept missing high-story-point work, and the business saw no incremental value. Twenty people across product, engineering and QA. VP sponsorship, no mandate (record).

T — Task. Convert to a predictable four-week cadence, and make the team own it so it would survive without me.

A — Action.

- **People discovery first.** One-on-ones across all three functions, mapping objections, motivations and who actually influenced whom. Then a named influencer in each function with specific objectives.
- **Give the hardest job to the most skeptical person.** The QA lead designed the definition of done with entry criteria. I coached by asking "what would make this safe for QA?" and let them write the answer.
- **Their ceremonies, my evidence.** The team authored the ceremony details. I built the Jira hygiene underneath: a business-benefit index so high-value stories slotted first, and a review-status gate before QA.
- **Make the work visible.** One weekly chart of what moved to QA on time, what moved and what didn't, failures included.
- **A written workflow guide** from grooming to done, so every status was captured the same way whoever touched it.

R — Result.

- **Hybrid → four-week cadence in six weeks** (record).
- **Critical defects −50%** (record, resume).
- Adoption held without a mandate, and **neighbouring teams copied the cadence** on their own (record).
- The QA lead's definition of done became the team's gate. It was later the QA gate my own in-transit fix had to pass (F3).

Who I influenced: the VP (air cover, not orders) · the QA lead (from blocker to author of the gate) · one named influencer each in product and engineering · neighbouring team leads (copied a result, not a name).

TRADE-OFF I MADE

Options: (a) draft the ceremonies and the definition of done myself, which is faster, or (b) let the team author them. I chose (b). I rejected (a) because a cadence imposed by me would die when I left the room. It cost control and time: drafts I could have written in a day took weeks of their sessions, and their version wasn't the one I'd have written.

Failure / learning: I should have gone to QA first. Their fear was a design requirement disguised as a complaint, and starting with the most skeptical function would have shortened the six weeks.

Hire & Develop the Best — I coached the QA lead into owning the team's quality gate.

Strive to be Earth's Best Employer — I advocated for QA's working window inside the design.

Think Big — drove adoption of a vision without a mandate, and it was copied by neighbours.

Earn Trust — published failures as visibly as wins.

PROBING — FOUR QUESTIONS HE WILL ASK

"You had no direct reports. Is this really developing people?"

Honestly, it's developing owners, not a direct report's career. I've led through programs, not org charts, and I say that up front. What transfers is making people who don't report to me own a standard.

"How did you coach the QA lead specifically?"

I gave them the blank page, not a draft. I asked them to define what "ready for QA" means in testable entry criteria, reviewed it with them before the team saw it, and let them present it.

"How do you know it was the cadence and not luck?"

The weekly chart before and after, and the critical-defect count halving. The strongest evidence is that other teams copied it without being asked.

"Raising the bar: who would you hire for this team now?"

Someone who writes the gate rather than waiting for one. The QA lead was that person once given the pen.

SAFE-SAY: "Twenty people, hybrid to a four-week cadence in six weeks, critical defects down by half. I had no direct-report org, and I say so."

"What's your source?" "My resume and the team's own cycle charts."

20-SECOND VERSION

"Twenty people, sponsorship but no mandate. I gave the most skeptical person, the QA lead, the pen on the definition of done. Their fear became the gate. Four-week cadence in six weeks, critical defects halved, and neighbouring teams copied it."

4 · Failures — Bar Raisers always ask (F1–F4) NEW

Rules: never open with these; own the miss in the first sentence; root cause in my own process; end on the standing control that outlived the program. G2 (the RF-device script) stays with P7 in the program packet. Choose by audience: **F1 is the strongest** (a customer-facing miss). Use F3 only if Ryan did not hear S4 yesterday.

F1 · The UAT that crashed — the performance criteria I never wrote FREE FAILURE

Company: Elementum, track-and-trace application · **Source:** Apple v11 G1 p43–44 (2022 onsite Failure doc) · **Numbers:** 5 key users × 10 E2E scenarios; crash 2 days before sign-off (record).

60-SECOND PITCH

"I lost a UAT sign-off at Elementum, and the failure was mine. Two days before sign-off, five key users had passed all ten end-to-end scenarios, and I was confident. Then the sponsor escalated: the system was buggy, and users couldn't finish a single flow. My first move was wrong. I re-ran the scenarios, they passed, and I sent screenshots saying it worked. I was defending instead of digging. The real cause: the sponsor had opened access to all their users, and concurrent logins crashed a system my UAT criteria never load-tested. I took it to the sponsor as my miss while the team simulated the concurrency and fixed it around the clock. The sign-off date passed. Since then every gate I run carries a load number. At Flexport, the launch gate required 500 containers in 20 minutes at 99.6% connectivity before any customer saw the product."

S — Situation. Track-and-trace UAT, sign-off two days out. **5 key users had completed all 10 E2E scenarios** (record). The sponsor escalated: buggy, flows unfinishable. The launch date and user confidence were at stake.

T — Task. Recover the launch and the sponsor's trust, and find out why my UAT said "pass" while the customer said "broken".

A — Action. (1) My first move was the failure: I re-ran the scenarios and emailed screenshots. (2) Then first principles: the noise said "buggy". The cause was concurrency, because the sponsor had opened access to all their users. (3) I took the miss to the sponsor as mine: my criteria covered explicit needs and ignored the implicit one, performance. (4) My team simulated the concurrency and shipped the fix round the clock. (5) I rewrote the UAT contract: numeric entrance and exit criteria on every critical scenario (uptime, page load, concurrent load), tested at the customer's shape.

R — Result. The sign-off date passed and confidence had to be rebuilt (record: missed). **The standing control:** every gate since carries a load line. The Flexport SV gate's performance proof was **500 containers in 20 minutes at 99.6% connectivity** before any customer testing (record-from-docs, TPM status 11/19/21), and the JDA UAT entrance criteria held.

TRADE-OFF I MADE (AND THE ONE I'D MAKE NOW)

Under deadline I traded depth of testing (five users, scenario coverage) for speed to sign-off, and didn't price the load risk. Now I'd trade two days of schedule for a concurrency test at the customer's user count every time.

Level 1, "What exactly did you do wrong?" I wrote criteria that tested what users asked for and not how they'd use it, and when it broke I defended with screenshots before reproducing their experience. The screenshots email is the moment I'd take back.

Level 2, "Wasn't the sponsor at fault for opening access?" No. Users use the system the way their day demands. It was an implicit requirement I failed to surface, so my criteria owned the gap.

Level 3, "How do you know the lesson stuck?" A number in a later program: the SV performance proof of 500 containers in 20 minutes at 99.6%, run before customers. And my first hour on any escalation now goes to reproducing the customer's shape, not proving our innocence.

Are Right, A Lot (AIQB Q5 — an error in judgment) · **Earn Trust** — owned it to the sponsor by name · **Insist on the Highest Standards** — the load line on every gate · **Customer Obsession** — the customer's experience was the truth.

SAFE-SAY: "Five users, ten scenarios, all passed, and it crashed under concurrent logins two days before sign-off. The sign-off date passed. That one was mine."

"What's your source?" "My own failure write-up from that program."

20-SECOND VERSION

"I lost a UAT sign-off because I tested the scenarios and never the load: concurrent logins crashed it two days out. Worse, I defended with screenshots first. Now every gate I run has a load number, like the 500 containers in 20 minutes at 99.6% before Flexport customers saw SV."

F2 · The security review I discovered instead of planned FAILURE

ALSO WITH JOSYULA — DIFFERENT ANGLE

Company: Flexport, the Snowflake pipeline that automated the weekly business review · **Source:** Apple v11 G3 p45–46; BRD SV Zendesk Data in Snowflake · **Numbers:** access review under-planned by two weeks (record); cut over on a ≤1% parallel-run gate (record). The HM heard the pipeline story, so I tell only the planning miss here.

60-SECOND PITCH

"A smaller failure with a long shadow. At Flexport I was replacing my manual four-system weekly review with a Snowflake pipeline, on ticket data that carried customer content. I had planned the extracts, the loads, metric parity and the parallel-run cutover gate. I had not planned the data-access security review. It surfaced mid-build and cost two weeks. I owned it upward the same day: the slip was my scoping, not engineering, because my BRD priced the build and never the review. I re-sequenced instead of stalling. The parallel run kept the Monday review alive on the manual path, so the program absorbed the two weeks without skipping a review. The control that outlived it: security lead time is planned, not discovered. It's a standing line on every data program since, with one kickoff question: whose approval does this data need, and how long does it take?"

S — Situation. Automating the weekly business review onto a Snowflake pipeline, on Zendesk ticket data carrying customer content. The plan covered build and parity, but not the access review.

T — Task. Land the pipeline without breaking the weekly review cadence, and fix the planning gap, not just this instance of it.

A — Action. (1) Owned it upward immediately as a scoping miss. (2) Root cause: I'd treated the access review as a formality, not a workstream with lead time, and customer content makes it a gate. (3) Re-sequenced: the manual path stayed live in parallel. (4) Closed the review properly: data classes named, who could read what, cross-reference table documented. (5) Added the kickoff checklist line.

R — Result. **Two weeks lost** on the review (record), **zero skipped review weeks**, and cutover on the manual-versus-pipeline **≤1% parity gate** (record). **Standing control:** security and access lead time is a named line with an owner, priced in the BRD next to build cost. The I1 agent had access boundaries designed in from day one.

TRADE-OFF I MADE

When it surfaced: (a) push the review through fast and cut over on time, or (b) keep the manual path alive two more weeks and close the review properly. I chose (b). It cost me another two weeks of hand-stitching the Monday review myself.

Level 1, "Two weeks is small. Why is it a failure?" Because it was structural, not situational. Every data program with customer content has an access review, so without a fix I'd hit the same wall on every one.

Level 2, "Did the parallel run save you by design?" By design and by luck. I built it as a correctness gate, and it happened to double as a schedule buffer. Now I plan for that: the old path stays live until the new one clears both correctness and access.

Level 3, "What's different at Amazon?" Amazon's data-sensitivity bar makes the access review the longest pole on most data programs. I'd schedule it at kickoff, with the owner and the lead time on the plan.

Ownership (AIQB Q2 — a commitment at risk, communicated) · **Earn Trust** — owned upward the same day · **Are Right, A Lot** — a systemic cause behind a small miss.

SAFE-SAY: "The access review cost two weeks because I hadn't planned it. The Monday review never skipped, because the manual path stayed live."

"What's your source?" "My program notes and the BRD for the Snowflake pipeline."

20-SECOND VERSION

"I planned the pipeline and forgot the data-access review. It cost two weeks. I owned it the same day and kept the manual review alive in parallel, so nothing skipped. Since then, security lead time is a kickoff line on every data program."

F3 · The in-transit promise rule I got wrong FAILURE

CHECK: RYAN'S ROUTER HAD S4 AS HIS FAILURE ANSWER

Company: Sephora, S/4HANA ↔ ISM availability model · **Sources:** GFiber v8 S4 p66–67; master S4; NUMBERS-RECON canon #56 · **Numbers:** lane σ ≈ 0.3 day → ~0.49-day promise window ≈ 95% coverage; oversell increase zero; kill switch never fired (all **user anchor** — Apple has the shape only). No dollar figure for the conversion I lost, and I won't invent one.

60-SECOND PITCH

"The first availability ruleset I wrote for Sephora's new inventory model barred every channel from promising units in transit. It felt safe. Within weeks of go-live, the Aging In-Transit and replenishment reports showed dotcom starved of fast movers that were reliably one day from the building, and we were losing conversion on those SKUs. The rule was mine. I built the evidence pack, said so in the first line, and reframed it as promise math rather than 'make in-transit count'. The new rule: promise in-transit only where the lane's ETA falls inside a per-lane window from receiving history, with an on-time floor and the aging report as a kill switch. I took it back through the same three signatories and released it on the normal monthly cadence as a signed change, not a side configuration. Sellable units came back on qualifying lanes, oversell didn't rise, and the kill switch never fired. The lesson: both sides of a rule get a number before it ships."

S — Situation. My v1 ISM ruleset excluded in-transit from every channel's availability. The Aging In-Transit and replenishment reports showed fast movers reliably one day out, with dotcom starved and conversion lost on those SKUs (user anchor; Apple has the shape).

T — Task. Correct my own policy without weakening oversell protection, through the same signatories: Supply Chain Strategy, Inventory Management and Inventory Accounting.

A — Action. (1) Evidence pack first, with "the v1 rule was mine" in the first line. (2) Rule redesign: promisable in-transit = units whose ETA is inside the lane's window *and* whose lane meets an on-time floor. The window came from receiving history: lane σ about 0.3 day gives a window of about half a day at roughly 95% coverage (user anchor). (3) Rejected both blanket options (all in-transit, or none) in writing. (4) Back-tested against receiving history, then added four regression cells to the node × channel test matrix, passing the QA definition-of-done gate. (5) Released as a signed FSD change on the normal cadence, with the aging report armed as a kill switch.

R — Result. Sellable units restored on qualifying lanes, **oversell increase zero**, **kill switch never fired** (user anchor). **Standing control:** "both sides of a rule get a number before it ships". Every later gate was set from data before the event: the Locus 98% pick bar and the 0.5% migration tolerance.

TRADE-OFF I MADE

In v1 I traded sales for safety, zero in-transit promising, without pricing the sales side. In v2: (a) promise all in-transit, (b) keep none, or (c) promise per lane inside a window, with a floor and a kill switch. I chose (c). It cost a slower fix (signed change, regression, monthly release) instead of a quick configuration flip.

Level 1, "What exactly was your mistake?" I wrote a rule with a number on one side only: oversell risk, priced at zero tolerance. I never priced the undersell. The rule was mine, not the configurators'.

Level 2, "How much did it cost?" The record doesn't hold a dollar figure for the conversion lost while I was wrong, and I won't make one up. What I can give you is the shape: fast movers one day out, starved for weeks.

Level 3, "Why not just flip a config?" Because a side configuration would have created a second, unsigned truth about "available", the exact vocabulary bug the program existed to kill. Same signatories, same cadence.

Are Right, A Lot (AIQB Q4 — a bad decision) · **Success & Scale** (Q2 — changed a decision because of unintended consequences for customers) · **Earn Trust** — owned through the same signatories · **Insist on the Highest Standards** — signed change, not a side fix.

SAFE-SAY: "My first rule barred in-transit everywhere and starved dotcom. I fixed it through the same three signatories with a per-lane window, oversell didn't rise, and the kill switch never fired."

"What's your source?" "The Aging In-Transit and replenishment reports and the signed FSD change. The lane numbers are my program anchors."

20-SECOND VERSION

"I wrote an availability rule that never promised in-transit. It felt safe and starved dotcom of fast movers one day out. I owned it, rebuilt it as a per-lane window with a floor and a kill switch, and took it through the same signatories. Oversell stayed flat. Lesson: both sides of a rule get a number."

F4 · Locus retail testing slipped three weeks — a vendor dependency I carried as a task, not a risk FAILURE P1/P3 — TOLD ONLY AS A FAILURE

Company: Sephora UDC, Locus robotics retail track (RTL) · **Sources:** Apple v11 C2 p24–25 and C3 p26; UDC_LOCUS_Retail_Track status (YELLOW; UAT window 2/28–3/15); prior Rocky v2 packet (escalation and re-slot facts) · **Numbers:** RTL testing slipped 3 weeks (record); Locus-side rows 86 of 836 = 10.3% (record); root cause of the vendor slip itself VERIFY.

60-SECOND PITCH

"On the UDC conversion, Locus robotics' retail-track testing slipped three weeks. The slip itself was a vendor-and-integration dependency, but the failure I own is how I carried it. It sat on my plan as a task with a date, not on the risk register with a trigger and an owner. So when it moved, I learned it from the status report, not from a tripwire I had set. What I did right after that: I escalated the week it surfaced, re-slotted the end-to-end chain openly in the plan's revision sheet, and refused to compress UAT to absorb it. The go/no-go bar, zero open blocker and critical issues, was set before the pressure and held. The combined go-live landed in May 2025, with zero customer-facing incidents. The control I run now: every vendor dependency on the critical path goes on the risk register with a trigger date and a named owner on both sides."

S — Situation. Locus design and build ran July–December 2024, RTL end-to-end completion was due January 31, and physical testing ran February–March 2025 (record, Apple C3). The retail-track status went YELLOW with integration items still open: the API approach (sockets versus REST), the retail customer-owner configuration, and tote-type mapping (record-from-docs, Locus Retail Track). RTL testing slipped three weeks (record).

T — Task. Protect the combined go-live and its quality bar without hiding the slip or squeezing UAT.

A — Action. (1) Escalated the week it surfaced, with the re-slotted dates attached. (2) Re-slotted the E2E chain openly in the plan's revision sheet, never silently absorbed into weekends. (3) Held UAT at full length rather than compressing it to buy back the three weeks. (4) Kept the go/no-go bar as set: blocker and critical open = 0. (5) Moved vendor dependencies from the task list onto the risk register, each with a trigger date and owners on both sides.

R — Result. The combined go-live **landed in May 2025** with **zero customer-facing incidents** (record). Locus-side issues stayed at **86 of 836 rows, about a tenth** of the program's log (record). **Standing control:** vendor critical-path items live on the risk register with a trigger and an owner, and a slipped vendor doesn't get to lower the bar.

TRADE-OFF I MADE

After the slip: (a) compress UAT and keep every original date, or (b) re-slot openly and hold UAT length. I chose (b). It cost three weeks of float on the chain and an uncomfortable steering update.

Level 1, "Whose fault was the slip?" The slip came from the vendor and integration track. I don't have a single root cause in my record, so I won't make one up VERIFY. My failure was carrying it as a task. Nobody had a trigger to pull earlier.

Level 2, "How would a risk entry have changed anything?" A trigger date ahead of the January 31 E2E milestone, with Locus and our WMS lead named, would have surfaced it earlier, while the float was cheaper.

Level 3, "What happened after?" The robotics gate still did its job: week two measured 94% against a 98% bar, about 30% of volume was throttled to manual carts, and full automation came in week three (record, P3). Gates set before the event held.

Ownership (AIQB Q2 — a commitment at risk, communicated) · **Insist on the Highest Standards** (Q4 — standards over delivery: UAT not compressed) · **Deliver Results** (Q6 — something didn't complete on time).

SAFE-SAY: "Locus retail testing slipped three weeks. I re-slotted openly, didn't compress UAT, and the combined go-live landed in May 2025 with zero customer-facing incidents."

"What's your source?" "The UDC build plan's revision sheet and the Locus retail-track status."

20-SECOND VERSION

"Locus retail testing slipped three weeks. My failure was carrying a vendor dependency as a task, not a risk with a trigger. I escalated that week, re-slotted openly and held UAT, and the May go-live landed clean. Now every critical-path vendor item has a trigger and an owner on the register."

5 · STAR answer bank — all 16 Leadership Principles, two real AIQB questions each NEW

Each card: the AIQB question quoted (cited "AIQB: <LP> Q#"), a spoken opener, a ~90-second S/T/A/R, the number to land, what NOT to say, the source story, and the likely three-level follow-up with its answer. None of these 32 question numbers were the router questions used with the hiring manager yesterday (she got CO Q8, Own Q3, I&S Q1, ARL Q1, L&BC Q4, HDB Q9, HSS Q4, TB Q2, BfA Q1, Frug Q1, ET Q2, DD Q3, Backbone Q1, DR Q3, EBE Q3, BR Q5). **32 answers from 17 distinct stories.**

The 16-row matrix — LP · primary story · backup story · the number

LP	PRIMARY (AIQB Q#)	BACKUP (AIQB Q#)	NUMBER TO LAND (BASIS)
Customer Obsession	R1 routing guide (Q6)	F1 UAT crash (Q1)	DQ ~40% reported / ~55% true → 99% (record)
Ownership	R5 trace ID (Q1)	F2 security review (Q2)	Blocker MTTR −50% (record-from-docs)
Invent & Simplify	R2 carrier bid (Q5)	R7 triage agent (Q2)	6 weeks → ~3 (user anchor)
Are Right, A Lot	R5 trace ID (Q7)	F3 in-transit rule (Q4)	2–4 hrs to locate a bug → MTTR −50% (record-from-docs)
Learn & Be Curious	R7 triage agent (Q2)	P3 Locus robotics (Q1)	$25 → $0.40 per incident (record)
Hire & Develop	R9 QA lead (Q4)	R3 site super-users (Q3)	4-week cadence in 6 weeks; critical defects −50% (record)
Highest Standards	R8 issues log (Q6)	P3 98% robot gate (Q1)	836 rows, 85.4% closed, 0 customer incidents (record)
Think Big	R1 Austria → 25 locations (Q1)	R9 cadence copied (Q4)	~$8M across 25 European locations (record)
Bias for Action	R6 two programs, one ruler (Q8)	P6 Cyber Monday (Q4)	~$200K/month per DC at stake (record)
Frugality	R7 cost per incident (Q4)	R3 snapshot-diffing (Q3)	−98% per incident (record)
Earn Trust	R4 Customs split (Q5)	P7 RF devices (Q4)	15 work items, one owner each (record-from-docs)
Dive Deep	R5 tracing metric (Q6)	R1 true DQ metric (Q5)	events-in ÷ events-out per hop (record-from-docs)
Backbone	R6 disagree & commit (Q3)	R2 "not an optimizer" (Q2)	landed inside 4 weeks (record)
Deliver Results	P1 UDC staged go-live (Q1)	P2 JDA mocks (Q2)	+15% processing efficiency; 7.0% → 0.3% (record)
Earth's Best Employer	R6 two-pass war room (Q5)	R9 advocated for QA (Q2)	45-minute forum; nobody on 24 hrs (record)
Broad Responsibility	R4 shared CtS goals (Q1)	F3 changed my rule (Q2)	oversell +0, kill switch never fired (user anchor)

Customer Obsession

AIQB: CUSTOMER OBSESSION Q6 **"Tell me about a time when a customer came to you for something that wouldn't actually address their need. How did you approach the situation? What was the result?"**

Opener: "The client asked me to hold carriers to their on-time SLA. What they needed was to be able to measure on-time at all."

S At Elementum, a client's Austria transportation team believed carriers were late. The report showed 40% data quality, and they spent 8–10 hours a week reconciling dates by hand. **T** They asked for carrier enforcement. I owned the analysis and the rules design. **A** I pulled three years of shipment history in SQL and showed the sponsor that true quality was about 55%. Nobody could prove a carrier was late on that data. I proposed the thing they hadn't asked for: fix measurement first, with a 99% data gate before the routing engine scaled, and a savings method co-written with Finance. **R** Quality reached 99% within a quarter. The Austria pilot measured about 97% on-time accuracy and about $500K a year, and the 25-location rollout closed at about $8M validated. Then carrier performance could be enforced on real numbers.

Land: 55% true vs 40% reported → 99%. **Don't say:** "the customer was wrong"; any lane count; "$1M". **Drawn from:** R1.

3-level follow-up. L1 "How did you tell them no?" → I didn't say no. I showed their own three years of data and asked what an SLA is worth at 55%. L2 "What if they'd insisted?" → I'd have enforced on the cleanest lanes only and published the quality caveat next to every penalty. L3 "What did the customer say after?" → They adopted the method across 25 locations, and Finance reused it.

AIQB: CUSTOMER OBSESSION Q1 **"Describe a difficult interaction you had with a customer. How did you deal with it? What was the outcome? How would you handle it differently?"**

Opener: "The most difficult one was my own fault: a sponsor told me the system was broken, and I sent screenshots saying it worked."

S Elementum track-and-trace UAT, sign-off two days out. Five key users had passed all ten scenarios. **T** The sponsor escalated: users couldn't finish a flow. I had to recover the launch and the relationship. **A** My first move was wrong: I re-ran the tests and sent screenshots. Then I reproduced their real shape. They had opened access to all users, and concurrent logins crashed the system. I called the sponsor, said the criteria were mine and had missed load, and my team fixed it round the clock. **R** The sign-off date passed. Trust came back because I owned the root cause. Every gate since carries a load number, like 500 containers in 20 minutes at 99.6% at Flexport.

Land: 5 users × 10 scenarios; crash 2 days out. **Don't say:** "the sponsor opened access too early" as blame. **Drawn from:** F1.

3-level follow-up. L1 "What would you handle differently?" → First hour of any escalation: reproduce their experience, not prove our innocence. L2 "Why did you defend first?" → I mistook my test coverage for the truth. L3 "How did you rebuild trust?" → I named the root cause as mine and changed the criteria so this class of miss can't recur.

Ownership

AIQB: OWNERSHIP Q1 **"Tell me about a time when you took on something significant outside your area of responsibility. Why was it important? What was the outcome?"**

Opener: "As the TPM, my job was the plan. I ended up proposing an architecture change, because nobody was looking at the seam between six systems."

S Flexport's Shipment Visibility: 6 systems, 9 teams, close to 100 people, on new infrastructure. **T** I owned delivery and the bug bash, not the design. **A** I read the application logs alongside the engineers and found that no unique ID tied an event from the downstream systems to the customer screen. Finding which system held a bug took 2–4 hours. I wrote up a design change for one traceable load-event ID end to end, with a drop metric at every hop, and got the Visibility, Ocean and Flexport OS managers to slot the stories. I also built the Datadog monitoring checklist for every connectivity point. **R** Blocker-bug MTTR fell by 50%, and we were monitored at every connectivity point before the customer-ready date.

Land: 2–4 hours to locate → MTTR −50%. **Don't say:** "I built the trace", since three teams built it. **Drawn from:** R5.

3-level follow-up. L1 "Did the engineering managers resent it?" → One pointed out the downstream system couldn't carry the ID yet, which was right, so it became a dependency with its own design doc. L2 "How was the 50% measured?" → Blocker troubleshooting before and after, from my own one-pager. L3 "What would you do earlier?" → Trace and monitors in sprint one, which was our own retrospective lesson.

AIQB: OWNERSHIP Q2 **"Describe a time when you didn't think you were going to meet a commitment you promised. How did you identify the risk and communicate it to stakeholders? Is there anything you would do differently?"**

Opener: "I committed to a pipeline date and found mid-build that I'd never planned the security review. I told my manager the same day that it was my scoping miss."

S Flexport: automating the weekly business review onto Snowflake, on ticket data with customer content. **T** Hold the commitment without skipping a weekly review. **A** When the access review surfaced, I priced it at two weeks and told leadership the slip was my scoping, because the BRD priced the build and never the review. I kept the manual four-system review running in parallel so the Monday review never skipped, closed the review properly with data classes and access rules, and cut over only at ≤1% parity. **R** Two weeks late on the review, zero review weeks skipped. Security lead time is now a kickoff line on every data program.

Land: two weeks; zero skipped reviews. **Don't say:** "security was slow". **Drawn from:** F2.

3-level follow-up. L1 "How did you find out?" → It surfaced mid-build when the data-access request hit review, and I hadn't scheduled it. L2 "Differently?" → Ask at kickoff whose approval the data needs and how long it takes, and price it in the BRD. L3 "Has it recurred?" → No. My later agent build had access boundaries designed in from day one.

Invent and Simplify

AIQB: INVENT AND SIMPLIFY Q5 **"Tell me about a time when you had a challenging problem or situation that the usual approach wouldn't address. How did you select an alternative approach? What alternative approach(es) did you consider? …"**

Opener: "Everyone wanted a better solver for the carrier bid. The problem wasn't the solver, it was the lane names."

S At Elementum, a client ran a semi-annual carrier bid: hundreds of lanes, dozens of rate files, about six weeks a cycle. **T** I owned requirements, constraint rules and the parallel run. **A** The usual approach was a stronger optimizer. Before choosing, I sat through a full cycle logging hours. Most of the time went to reconciling lane and mode names across carriers. I considered (a) a new solver, (b) manual cleanup staff, and (c) a lane master with explicit constraint rules, and chose (c). The gate was under 5% mismatch against the last two real awards before the tool's output counted, and we parallel-ran it on one region's live bid. **R** The cycle went from about six weeks to about three, and the pilot region finished three weeks early. Other regions adopted it without a mandate (user anchor).

Land: 6 weeks → ~3. **Don't say:** any award savings dollar. **Drawn from:** R2.

3-level follow-up. L1 "Why not both solver and lane master?" → The solver was fine once inputs matched, so a new one would have been cost without benefit. L2 "Why 5%?" → It had to beat planners' trust in the last two awards. L3 "Who disagreed?" → Procurement, late. They were right about two award rules, which I added.

AIQB: INVENT AND SIMPLIFY Q2 **"Describe the most innovative thing you've done and why you thought it was innovative. … What was the problem it was solving? What was innovative about it?"**

Opener: "The most innovative thing I've built is the least flashy: an LLM triage agent that refuses to propose anything it can't cite, at forty cents an incident."

S An independent build: LLM triage for operational incident queues. The naive version cost $25 an incident. **T** Make it an operations tool: accurate, traceable, under $1. **A** The innovation was the discipline, not the model. I built an eval set before the agent (graded historical incidents, where the past must keep passing), a hard rule of no citation, no proposal, and tiered routing with small models on easy classes and expensive calls only on the hard tail. **R** $25 → $0.40 per incident, a 98% cut, with accuracy held and 100% citation coverage. *Pattern, second example:* the trace-ID design on SV (R5).

Land: $25 → $0.40, 100% citations. **Don't say:** that it was deployed at an employer. **Drawn from:** R7.

3-level follow-up. L1 "What's innovative about routing?" → Proving the cheap path on the eval set before moving traffic, which most demos skip. L2 "Why citations?" → An untraceable proposal makes a human redo the work, while a cited one takes thirty seconds to check. L3 "What would break at Amazon?" → Eval upkeep and the data-access review, both of which I'd schedule at kickoff.

Are Right, A Lot

AIQB: ARE RIGHT, A LOT Q7 **"Describe a time when you brought different perspectives together to solve a problem. What types of different perspectives were represented? How did you seek out different points of view? What was the outcome? …"**

Opener: "Each of three engineering teams saw its own hop. I put the product view, the engineering view and the operations view on one seam."

S Shipment Visibility bug bash: data crossing six system layers owned by different teams, with 2–4 hours to locate each blocker. **T** Converge the bug bash and decide how to test 3PL volume safely. **A** I brought engineering managers (what each system can carry), product (what the customer screen must show) and the DRI (customer risk) into one pros-and-cons review. Outcomes: a trace-ID design change across Visibility, Ocean and Flexport OS; a load-event tracing metric; and, for 3PL testing, a production client test account instead of staging, restricted to named clients and lanes, with a kill-switch list and 10% shipment spot checks. **R** MTTR on blocker bugs fell by 50%, and the test ran in production without client disruption.

Land: MTTR −50%. **Don't say:** "staging was useless". The trade-offs were analyzed. **Drawn from:** R5.

3-level follow-up. L1 "Who disagreed on production?" → Risk-averse voices preferred staging, and the kill switches and client/lane restriction were their price for agreeing. L2 "Were they right?" → Partly. Staging was safer, but it couldn't show real 3PL data paths. L3 "Learning?" → Write the "not a goal" list. We explicitly excluded performance and cost-to-serve from that test.

AIQB: ARE RIGHT, A LOT Q4 **"We don't always make the right decision all the time. Tell me about a time when you made a bad decision. What was the impact of that decision? What did you learn? How have you applied what you learned?"**

Opener: "I wrote an availability rule that never let any channel promise stock in transit. It felt safe, and it starved dotcom."

S Sephora's new ISM availability model. My v1 ruleset excluded in-transit everywhere. **T** Fix my own rule without weakening oversell protection. **A** The Aging In-Transit and replenishment reports showed fast movers one day out and conversion lost. I wrote the evidence pack with "this was my rule" in the first line and redesigned it as a per-lane promise window from receiving history, with an on-time floor and a kill switch. I took it back through the same three signatories as a signed change on the normal release cadence. **R** Sellable units restored on qualifying lanes, oversell up zero, kill switch never fired. Applied since: both sides of a rule get a number. The Locus 98% gate and the 0.5% migration tolerance were both set before the event.

Land: oversell +0; kill switch never fired (user anchor). **Don't say:** a lost-sales dollar. There isn't one in the record. **Drawn from:** F3 (use F1 if Ryan heard S4).

3-level follow-up. L1 "Why was it bad, not just conservative?" → I priced one side only. L2 "Why not a quick config change?" → A side config is a second, unsigned truth about "available", the bug the program existed to kill. L3 "How long were you wrong?" → Weeks after go-live, until the reports showed it.

Learn and Be Curious

AIQB: LEARN AND BE CURIOUS Q2 **"Describe a time when you took on work outside of your comfort area. How did you identify what you needed to learn to be successful? How did you go about building expertise to meet your goal? Did you meet your goal?"**

Opener: "I learned LLM engineering by building a production-shaped agent myself, not by reading about it."

S I'm a program leader, and LLM engineering was outside my comfort zone. **T** Build an incident-triage agent good enough for operations: accurate, cited, under $1 an incident. **A** I worked out what to learn from the failure modes: cost, hallucinated actions, regressions. I learned each by building the control for it: an eval set to catch regressions, a citation layer to stop unsupported proposals, and model routing for cost. Stack: Python, FastAPI, LLM tool use, SQLite. **R** $25 → $0.40 per incident, 100% citations, accuracy held. Goal met and exceeded.

Land: −98% per incident. **Don't say:** "I'm an ML engineer". **Drawn from:** R7.

3-level follow-up. L1 "What was hardest to learn?" → Evaluation: what "correct triage" means, graded and versioned. L2 "What would you do differently?" → Freeze eval-set v1 on day one. L3 "How does it apply here?" → The same gate-before-trust logic I'd put on any automation in infrastructure operations.

AIQB: LEARN AND BE CURIOUS Q1 **"Tell me about a time when you realized you needed a deeper level of subject matter expertise to do your job well. What did you do about it? What was the outcome? …"**

Opener: "I'd never landed warehouse robotics. I needed to understand the floor before I could set a gate the robots had to pass."

S Sephora UDC: Locus robots on the retail outbound floor, inside a live WMS conversion. **T** Set a go-live gate I could defend. **A** I ran a three-day Locus workshop (July 29 to August 2, 2024) covering the facility tour, bot map, pick zones, induction rules, the dotcom-versus-retail priority contention, tote types and WMS integration requirements. I had the interfaces unit-tested with simulated data first. From that, I set a 98% pick-accurate throughput bar (99% stretch) before the robots arrived, with manual carts as the planned fallback. **R** Week two measured 94%. About 30% of volume was throttled to carts, zone logic was fixed, and full automation came in week three. The gate worked because I understood what it measured.

Land: 98% bar, 94% in week 2, full automation in week 3. **Don't say:** "the robots failed". **Drawn from:** P3 (program-packet primary).

3-level follow-up. L1 "Why 98%?" → That's where the customer promise lives for retail picks. L2 "Who wanted to push through at 94%?" → The pressure to keep the date. The throttle was a dial we'd already built. L3 "After?" → The bar set before the event became my default (see F3).

Hire and Develop the Best

AIQB: HIRE AND DEVELOP THE BEST Q4 **"Tell me about a time when you provided coaching for a team member. What started the coaching? What was the outcome?"**

Opener: "The most skeptical person on the team was our QA lead. I coached them into writing the gate everyone else had to pass."

S Sephora: a 20-person product, engineering and QA team moving from six-week hybrid cycles to a four-week cadence. VP sponsorship, no mandate. **T** Make the cadence stick, which meant QA had to own quality, not fear it. **A** QA feared their testing window would be crushed. That fear started the coaching. I gave the QA lead the blank page for the definition of done with entry criteria, asked "what would make this safe for QA?", reviewed drafts one-on-one, and had them present it to the team. **R** A four-week cadence in six weeks, critical defects down 50%, and the QA lead's definition of done became the team's gate. Neighbouring teams copied it.

Land: 6 weeks; critical defects −50%. **Don't say:** "my direct report". I had none. **Drawn from:** R9.

3-level follow-up. L1 "What did you actually say to them?" → I asked questions rather than giving a draft, and reviewed in private before the team saw it. L2 "Did it ever not work?" → It took longer than if I'd written it myself, and I'd start with QA earlier. L3 "Raise the bar?" → I'd hire people who write the gate rather than wait for it.

AIQB: HIRE AND DEVELOP THE BEST Q3 **"Give me an example of a time you provided feedback to develop the strengths of someone on your team. Were you able to positively impact their performance?"**

Opener: "On a six-site rollout I made each site's super-user the owner of their own data maps, and fed their reconciliation results back to them every week."

S Elementum: a contract manufacturer's data across six site systems with six definitions of the same fields. **T** Roll out site by site, with the capability living at the site, not with me. **A** Each site named a super-user who owned that site's mapping tables. On the weekly call, the per-site reconciliation report was their feedback loop: where they matched, where they didn't, why. I built on their strength, local knowledge of what a field really meant at their site, and let them correct the maps where the source's real numbers disagreed with its documentation. **R** Six sites in three waves over about five months, and the super-users kept the maps after go-live (user anchor). *Honest frame:* these were site owners, not direct reports.

Land: 0 → 6 sites in three waves (user anchor). **Don't say:** headcounts or promotions. None are in the record. **Drawn from:** R3.

3-level follow-up. L1 "Example of the feedback?" → Where the weekly reconciliation showed a mismatch, the super-user traced whether their map or the source documentation was wrong, and fixed their own map. I reviewed it with them; I didn't do it for them. L2 "Did anyone struggle?" → The legacy site, with no change-data-capture, took six weeks against three, so we gave them snapshot-diffing. L3 "People management?" → I've led through programs, not org charts, and I say so.

Insist on the Highest Standards

AIQB: INSIST ON THE HIGHEST STANDARDS Q6 **"Describe the most significant continuous improvement project that you led. What was the catalyst to this change and how did you go about it? What was the outcome?"**

Opener: "The catalyst was simple: on a thirty-track warehouse program, status by opinion would have drowned us. So I made readiness a count."

S Sephora UDC: two warehouses into one omni building, about a dozen systems, 60-plus stakeholders, about thirty build tracks. **T** Make every go-live call off counted rows. **A** One consolidated issues log with one grammar (status, priority, operation, area, owner, date), no side lists, and a weekly dedupe. Blocker and critical rows (441 of 836, 52.8%) led every review, and each red had a name and a date. A parking-lot status meant "decided not now", in writing. Then I made the log the gate: both go-lives read burn-down curves. **R** 836 rows, 85.4% closed. The June 2025 spike of 271 burned down 65, 21, 14, 4. Zero customer-facing incidents at both go-lives.

Land: 836 rows; 85.4% closed; 271 → 4. **Don't say:** "836 bugs". Only 115 were bugs. **Drawn from:** R8.

3-level follow-up. L1 "What made it continuous, not one-off?" → The weekly read and dedupe, run for the whole program. L2 "What did the data change?" → An owner's queue growing two weeks running triggered a resourcing conversation with evidence. L3 "Differently?" → Monthly-shape view from the first hundred rows.

AIQB: INSIST ON THE HIGHEST STANDARDS Q1 **"Describe a time when you refused to compromise your standards around quality/customer service, etc. Who was your customer? What was the result?"**

Opener: "In week two the robots measured 94% against a 98% bar I'd set before they arrived. I throttled them rather than lower the bar."

S Sephora UDC: Locus robotics on retail outbound inside a live WMS conversion. **T** Protect the retail customer's pick accuracy while landing automation. **A** I'd set the bar at 98% pick-accurate throughput (99% stretch) before the bots arrived, with manual carts as a planned fallback. When week two read 94%, there was pressure to keep full volume on the robots. I moved about 30% of volume back to manual carts, got the zone-logic fix in, and re-measured. **R** Full automation in week three, and the customer was never the test. The customer was the stores and dotcom shoppers downstream of those picks.

Land: 98% bar; 94% → throttle ~30% → full automation in week 3 (record). **Don't say:** "the robots failed". The gate worked. **Drawn from:** P3.

3-level follow-up. L1 "Who pushed to keep volume on?" → The schedule pressure. My answer was that the throttle was a dial we'd already built. L2 "What did the throttle cost?" → Manual labour for about a week on 30% of volume. L3 "Would you set 98% again?" → Yes, because that's where the customer promise lives.

Think Big

AIQB: THINK BIG Q1 **"Tell me about time when you were working on an initiative or goal and saw an opportunity to do something much bigger or better than the initial focus. Did you take that opportunity? Why or why not? What was the outcome?"**

Opener: "The ask was one Austrian site's carrier problem. I built it as a method for twenty-five locations."

S Elementum: the client's Austria site couldn't measure on-time delivery, with 40% reported data quality. **T** Initial focus: fix Austria. **A** I designed everything to travel. The rules engine was keyed on ship-from, ship-to, mode, volume, Incoterm and SLA. The savings method was co-written with Finance and per-shipment auditable. The data gate was 99% before scale, and there was a one-page runbook with regional super-users. Then I ran Austria as the pilot on the ugliest carrier mix and let its numbers make the scale call. **R** The pilot went live inside a month at about 97% on-time accuracy and about $500K a year. The rollout covered 25 European locations, with about $8M of validated freight savings, and Finance reused the method.

Land: ~$8M across 25 European locations. **Don't say:** "400-plus lanes"; "$1M". **Drawn from:** R1.

3-level follow-up. L1 "Why not scale faster?" → The engine waits for the data. L2 "How did you track adoption?" → Sites added by one rules file plus one data-quality cycle (user anchor), and Finance-audited claims per site. L3 "What would you change?" → Settle the audit-ledger format during the pilot.

AIQB: THINK BIG Q4 **"Tell me about a time when you drove adoption for your vision/ideas. How did you know your vision/idea was adopted by others? How did you drive adoption for your vision/ideas? How did you track adoption? …"**

Opener: "I knew the cadence was adopted when teams I'd never talked to copied it."

S Sephora: a 20-person team on six-week hybrid cycles, missing high-value stories. **T** Vision: predictable four-week delivery, owned by the team. **A** I drove adoption through the people, not a mandate: one-on-ones across functions, a named influencer in each, and the most skeptical person (QA) writing the definition of done. I tracked it with one chart, published every cycle, showing stories reaching QA on time and what moved and what didn't. **R** A four-week cadence in six weeks, critical defects down 50%. Adoption showed in two ways: the team kept it without a mandate, and neighbouring teams copied it.

Land: 6 weeks; −50% critical defects; copied by neighbours. **Don't say:** "I rolled agile out to the org". **Drawn from:** R9.

3-level follow-up. L1 "How do you know it wasn't the VP's authority?" → She gave air cover, not orders, and the team chose it every Monday. L2 "What didn't get adopted?" → My own drafts. The team's version replaced them. L3 "Differently?" → Start with QA.

Bias for Action

AIQB: BIAS FOR ACTION Q8 **"Tell me about a time when you were able to remove a serious roadblock/barrier preventing your team from making progress. What was the barrier? How were you able to remove it? What was the outcome? …"**

Opener: "The roadblock was two programs fighting over one engineering team. I removed it by putting both on one ruler inside a week."

S Flexport, 2022: leadership pulled a strategic go-live forward a month and shared my engineers. About $200K a month per DC of savings was at stake. **T** Keep both programs moving with one team. **A** The barrier was context-switching and priority arguments. I set up one RAID log, one 45-minute daily forum and one ruler: true blocker, non-blocker, or requirements gap. Within about a week most "blockers" were reclassified. True blockers went to a two-pass onsite/offshore war room with written handoffs, and escalations went up the same day as priced choices. **R** The compressed program landed inside four weeks, mine held its original date, and the business adopted on time.

Land: ~$200K/month per DC; inside 4 weeks. **Don't say:** "$1M per DC" first. Quote the rate. **Drawn from:** R6.

3-level follow-up. L1 "What did you personally rule on?" → I chaired the forum's classification calls and framed the escalations. L2 "What if leadership had refused a priced choice?" → Then the floor (blockers to agreed level) would have decided go/no-go, not the calendar. L3 "Cost?" → The team's calendar, which I named.

AIQB: BIAS FOR ACTION Q4 **"Tell me about a time when you had to gather information and respond immediately to a situation. What was the outcome? Would you have done anything differently?"**

Opener: "Cyber Monday, 4 AM: the VP called because backorders were piling up with inventory on the shelf."

S Manhattan Associates: I ran distribution OMS programs for a major retailer, 3 DCs and 100 stores, and owned holiday monitoring. About $6M of sales was on the line. **T** Stop the bleeding before the morning surge. **A** My own alerts named the signal: backorder variance on critical order types. I ran one bridge, one log and one decision list, every call timestamped. The noise said capacity. The trace said the allocation scheduler had stopped silently at the daylight-saving change. I triaged on promise-at-risk first, rebalanced allocation across DCs, confirmed with the client's business team, restarted, and sent status every two hours until 9 PM. **R** Fill rate held at 99% against a 95% goal, and about $8M of the day's sales was protected. The post-mortem added a scheduler heartbeat, so silence itself became an alarm.

Land: 99% vs 95%; $6M on the line → ~$8M protected (record). **Don't say:** $8M as both "at risk" and "protected". **Drawn from:** P6 (also with Josyula as S13; tell this incident-command angle).

3-level follow-up. L1 "What did YOU decide at 4 AM?" → Promise-at-risk first, and the DC rebalance, signed in the log. L2 "Differently?" → The heartbeat should have existed before peak. Silence wasn't monitored. L3 "After?" → The next peak ran boring.

Frugality

AIQB: FRUGALITY Q4 **"Tell me about a time when you had to make tradeoffs between quality and cost. How did you weigh the options? What was the result? Would you have done anything differently?"**

Opener: "Twenty-five dollars an incident was accurate but unaffordable. I got it to forty cents without giving up accuracy, and the eval set is how I proved it."

S My LLM triage agent: accurate, but at $25 an incident. **T** Under $1 an incident with accuracy held. **A** I weighed it per class, not overall. The eval set showed which incident classes a small model handled at equal accuracy. Those went to cheap models, and expensive calls were reserved for the hard tail. Every routing change had to keep the eval set passing, so cost could only fall where quality was proven. **R** $25 → $0.40, −98%, accuracy held, 100% citations.

Land: −98%. **Don't say:** "no trade-off at all". The trade was build time for the eval set. **Drawn from:** R7.

3-level follow-up. L1 "Where did you accept lower quality?" → Nowhere on the eval set. The cost was upfront engineering time. L2 "Differently?" → Version the eval set on day one. L3 "At scale?" → Eval upkeep becomes its own program line.

AIQB: FRUGALITY Q3 **"Tell me about a time when you didn't have enough resources to do something you felt was important but found a creative way to get it done anyway. What was the situation? What other options did you consider? …"**

Opener: "One site couldn't fund the system upgrade we needed, so we detected changes ourselves by diffing their flat-file snapshots."

S Elementum: a six-site contract-manufacturer rollout. The third-wave site ran a legacy system with flat files and no change-data-capture. **T** Get it to planning grade without a budget for an upgrade. **A** Options: (a) wait for the site to upgrade, (b) manual weekly reloads, (c) snapshot-diffing on the flat files to detect changes. I chose (c), scheduled the site last with buffer, and kept the same reconciliation gate as every other site. **R** Live in six weeks against a three-week average, absorbed in the plan, and all six sites were live in about five months (user anchor).

Land: 6 weeks vs 3 (user anchor). **Don't say:** a dollar figure. None in record. **Drawn from:** R3.

3-level follow-up. L1 "Who built the diff?" → Data engineering, from my requirement. L2 "Risk?" → Missed intra-day changes, acceptable at planning cadence. L3 "Differently?" → Sample reconciliation before writing the spec.

Earn Trust

AIQB: EARN TRUST Q5 **"Tell me about a time when your team's goals were out of alignment with another team you relied on in order to meet your goal. How did you work with the other team? Were you able to achieve your goals?"**

Opener: "Customs Platform and our forwarding app were both building export customs. Fifteen work items, and two teams who each thought some were theirs."

S Flexport, 2022: the 2023 plan had 15 work items, 12 export and 3 import, overlapping between Customs Platform and the FF App. **T** Get one owner per item before build planning, since we relied on Customs for licensed filings. **A** I proposed a principle (customs owns planning and filing, the app owns moving cargo onto a vessel) and one table per item: user group, exists in core, proposed owner, notes. We worked it row by row in two sessions, decided on qualification (only licensed brokers file AES and ISF), and put APIs at the seams: create, amend, query and delete for AMS. **R** On Nov 3, 2022, the FF App took ownership of all export items except ISF filing, AMS and AES ran through Customs APIs, and both teams shared the cost-to-serve goal.

Land: 15 items; one owner each except ISF. **Don't say:** "I wrote it" unless confirmed VERIFY. **Drawn from:** R4.

3-level follow-up. L1 "What did you give up?" → EAD stayed offline for now, and China documents may be revisited in 2025. L2 "Who was hardest?" → On AES and ISF, the right business owner wasn't in session one. L3 "Did delivery follow?" → The doc records the agreement, not a later delivery metric, so I don't claim one.

AIQB: EARN TRUST Q4 **"Give me an example of a time when you were not able to meet a commitment. What was the commitment and what were the obstacles that prevented success? What was the impact to your customers/peers and what did you learn from it?"**

Opener: "I committed a training sign-off date on our WMS upgrade and missed it by a week and a half, on a task everyone had called three days."

S Sephora RP → JDA: two DCs in eight months. Training sign-off was a go-live exit criterion, gated on hundreds of RF guns, printers and workstations converting. **T** Hold the training date. **A** The device task was estimated at 3–4 days, and I planned it as low effort. I scheduled a device test before training anyway, and the upgrade script failed on new hardware. With key people on COVID night shifts, the manual conversion couldn't finish in time. I told leadership directly: training slips 1.5 weeks, and it's my miss. **R** Training slipped 1.5 weeks. The program still landed on time and about 3% under budget. Learned: impact, not effort, decides a task's attention, so every cross-functional dependency now gets a what-if plan.

Land: hundreds of devices; +1.5 weeks; ~3% under budget (record). **Don't say:** an exact device count. **Drawn from:** P7 (G2) in the program packet.

3-level follow-up. L1 "Whose estimate?" → The devices team's, but accepting an effort estimate as a risk assessment was mine. L2 "Impact to peers?" → SME windows were scarce, so trainers re-planned. L3 "Applied since?" → Mock cutovers 7.0% → 1.8% → 0.3% against a 0.5% tolerance.

Dive Deep

AIQB: DIVE DEEP Q6 **"Have you ever created a metric that helped identify a need for a change in your department? What was the metric? Why did you create it? How did this and other information influence change? What was the outcome of the change?"**

Opener: "I created a drop ratio at every hop between six systems: events arriving divided by events sent. It showed exactly where data died."

S Flexport Shipment Visibility: data crossed six system layers, and locating a blocker took 2–4 hours. **T** Make data loss visible per system so the right team fixed the right thing. **A** I defined the load-event tracing metric at each hop (Visibility → Ocean → Flexport OS → Client App): events in the originating system ÷ events in the destination, and events dropped ÷ events planned. It required a unique trace ID end to end, which I proposed as a design change. For the 3PL test I made this ratio the success metric and wrote down what wasn't a goal: performance and cost-to-serve. **R** Blocker-bug MTTR fell by 50%. Engineering investigated specific dropped or erroneous trace IDs instead of guessing, and product spot-checked 10% of shipments.

Land: 2–4 hours → MTTR −50% (record-from-docs). **Don't say:** a drop-rate percentage. None is recorded. **Drawn from:** R5.

3-level follow-up. L1 "Why per hop, not end to end?" → End to end tells you that data died, and per hop tells you where. L2 "What other info mattered?" → The Datadog monitors for P95 event age and stream blockage per connectivity point. L3 "What would you do earlier?" → Put the metric in sprint one.

AIQB: DIVE DEEP Q5 **"Tell me about a specific metric you have used to identify a need for a change in your department. Did you create the metric or was it already available? How did this and other information influence the change? What was the outcome of this change?"**

Opener: "The available metric said data quality was 40%. I measured it myself at shipment grain, got 55%, and that changed the whole program."

S Elementum: the client's Austria transportation team. The reported data-quality metric of about 40% was used to blame carriers. **T** Find out what was actually broken. **A** I didn't trust the available metric's grain. I pulled three years of shipment history in SQL, measured quality per field class at shipment grain (about 55% true), and counted defects by class: missing rates, wrong-grain lanes, five spellings of carrier names, brochure transit times. That reframed the change from "penalize carriers" to "fix measurement", with a 99% gate and a weekly burn-down per defect class. **R** 99% within a quarter, Austria pilot about 97% accurate and about $500K a year, and about $8M validated across 25 European locations.

Land: 40% reported → 55% true → 99%. **Don't say:** "two months" or "three months". Say "within a quarter". **Drawn from:** R1.

3-level follow-up. L1 "Why was 55% higher than 40%?" → The report's grain penalized records that were usable at shipment grain, but neither number could hold a carrier to an SLA. L2 "How did you know the defect classes were the right ones?" → Each was counted and burned down weekly, and quality moved as they closed. L3 "Who owned each class after?" → Named owners, then regional super-users.

Have Backbone; Disagree and Commit

AIQB: HAVE BACKBONE; DISAGREE AND COMMIT Q3 **"Often, we must make decisions as a group. Give me an example of a time you committed to a group decision even though you disagreed. What factors led you to commit to the decision? Would you make the same decision now?"**

Opener: "Leadership decided to pull another go-live forward a month and take my engineers to do it. I disagreed, said so with the cost attached, then committed completely."

S Flexport, 2022: two programs, one shared team, an immovable new date. **T** Make the decision work, including for my own program. **A** I disagreed visibly but briefly, framing it as a priced choice rather than a complaint. What made me commit: about $200K a month per DC was at stake, so the pull-forward was probably right. Then I committed with mechanisms, not words: one RAID log, one 45-minute daily forum, one blocker ruler and a two-pass war room. **R** The compressed program landed inside four weeks and mine held its original date. Would I do it again? Yes. Disagree-and-commit only works if the disagreement was visible first.

Land: inside 4 weeks; both landed. **Don't say:** "I won the argument". I didn't. **Drawn from:** R6.

3-level follow-up. L1 "What did you say in the room?" → "Here's what A costs and what B costs." L2 "Was leadership right?" → On the priced numbers, probably yes. L3 "What did commitment cost you?" → My team's calendar, which I guarded with the 45-minute cap.

AIQB: HAVE BACKBONE; DISAGREE AND COMMIT Q2 **"Describe a time when you took an unpopular stance in a meeting with peers and your leader. What was it? Why did you feel strongly about it? What did you do? What was the outcome?"**

Opener: "The room had decided the carrier bid needed a better optimizer. I said it wasn't an optimization problem."

S Elementum: the client's semi-annual carrier bid, about six weeks a cycle. The expected fix was a stronger solver. **T** I owned requirements, and buying the wrong thing would have wasted a cycle. **A** I felt strongly because a better solver on mismatched lane names gives faster wrong answers. Instead of arguing, I asked for one cycle to observe, logged the hours by activity, and brought back the time audit: most of the six weeks was reconciliation. I proposed a lane master, explicit constraint rules, a less-than-5% match gate against the last two awards, and a written rejection of a black box. **R** The cycle went from about six weeks to about three, and the pilot region finished three weeks early. Other regions adopted it without a mandate (user anchor).

Land: 6 → ~3 weeks (user anchor). **Don't say:** award savings. **Drawn from:** R2.

3-level follow-up. L1 "How did your leader react?" → They agreed to one observed cycle, and the audit did the arguing. L2 "What if the audit had said optimization?" → Then I'd have built the solver, since the audit was the test of my view, not decoration. L3 "Miss?" → Procurement late.

Deliver Results

AIQB: DELIVER RESULTS Q1 **"Give me an example of a time when you were able to deliver an important project under a tight deadline. What sacrifices did you have to make to meet the deadline? How did they impact the final deliverable? What was the final outcome?"**

Opener: "Two warehouses into one live omni building, with a peak-season freeze we couldn't move. I gave up the single go-live to make the dates."

S Sephora UDC: about a dozen systems, 60-plus stakeholders, about thirty build tracks, with an October–December peak freeze. **T** Land it without touching peak or the customer. **A** The sacrifice was scope sequencing. Instead of one big-bang date, PO creation went live in January 2025 and the combined go-live followed in May 2025. I ran the gate chain on counted rows, a 343-task cutover plan of about 815 task-hours, and pre-written rollback triggers: sync below 99% for 4 hours, or p95 above 2× for 1 hour. **R** Zero customer-facing incidents, processing efficiency up 15%. The cost of the sacrifice was a longer hypercare tail across two go-lives.

Land: 0 customer incidents; +15% (record). **Don't say:** "twenty-plus systems"; "fifteen tracks". **Drawn from:** P1.

3-level follow-up. L1 "Who wanted one date?" → The prevailing instinct, because it's simpler to announce. L2 "Did rollback ever fire?" → No, but the triggers were written so nobody debated at 2 AM. L3 "Differently?" → Vendor dependencies on the risk register from day one (F4).

AIQB: DELIVER RESULTS Q2 **"Tell me about a time when you had significant, unanticipated obstacles to overcome in achieving a key goal. What was the obstacle? Were you eventually successful? Knowing what you know now, is there anything you would have done differently?"**

Opener: "Our first mock cutover on the WMS migration came in at 7% reconciliation error against a half-percent tolerance."

S Sephora RP → JDA: two DCs onto a new WMS in eight months, a domain I'd never run. **T** Go live inside the 0.5% reconciliation tolerance I'd published with Finance before mock one. **A** The unanticipated obstacles: mock one at 7.0%, with defect classes in UoM mappings, location-naming drift and open-order status vocabularies, then an RF-device script that failed on new hardware. I ran each defect class to an owner, re-ran the full dress rehearsal, and held the tolerance. Then a 72-hour freeze, and RP kept read-only for 30 days. **R** Mocks went 7.0% → 1.8% → 0.3% against 0.5%, the migration landed in eight months, about 3% under budget, and hypercare exited in week three of four.

Land: 7.0 → 1.8 → 0.3% vs 0.5%; ~3% under (record). **Don't say:** any multiplier; "$2.5M a month" without "my division". **Drawn from:** P2.

3-level follow-up. L1 "Why publish the tolerance before mock one?" → So nobody could renegotiate it once the number was red. L2 "What would you change?" → A what-if on every dependency, including the RF devices. L3 "Who did the fixing?" → 14 core plus 6 DC Ops. I owned the scorecard and the gate.

Strive to be Earth's Best Employer

AIQB: EARTH'S BEST EMPLOYER Q5 **"Tell me about a time when you showed compassion toward someone during a stressful or high-pressure situation. How did you recognize that it was important to demonstrate sensitivity? What did you do to demonstrate compassion? What were the outcomes for that person and the situation?"**

Opener: "When a go-live was compressed onto my team, the easy move was to have everyone work around the clock. I designed it so nobody had to."

S Flexport, 2022: the go-live was pulled forward a month and the same engineers were shared across two programs. **T** Keep 24-hour issue velocity without burning people out. **A** I recognized it in the forum: people were context-switching across two programs and answering at all hours. I set up a two-pass war room, onsite then offshore, with written handoffs, so work moved round the clock but each person worked their own day. I capped the daily forum at 45 minutes and defended the cap. I reclassified non-blockers so engineers stopped firefighting non-bugs, and escalated priced choices upward so the team didn't carry the decision. **R** Both programs landed, the compressed one inside four weeks. I name the honest cost: weeks of two-pass days on the team's calendar.

Land: 45-minute forum; nobody worked 24 hours. **Don't say:** "no one was stressed". **Drawn from:** R6.

3-level follow-up. L1 "How did you know it mattered?" → Context-switching between two masters was visible in the forum. L2 "What did people say?" → The handoff notes replaced late-night pings. That is the outcome I can stand behind VERIFY feedback quotes. L3 "Differently?" → Ship the floor guide earlier so DC users weren't stressed either.

AIQB: EARTH'S BEST EMPLOYER Q2 **"Tell me about a time when you advocated for someone who had less influence or seniority than you. How or why did you advocate for them and what was the outcome?"**

Opener: "In our agile conversion, QA had the least influence and the most to lose, so I made sure their working window was protected by design."

S Sephora: a 20-person team moving to a four-week cadence. QA feared compressed testing windows, and peers assumed four weeks meant more work in less time. **T** Make the change safe for the function with the least leverage. **A** I advocated in the design itself. The QA lead wrote the definition of done with entry criteria, so stories couldn't arrive at QA half-ready. I presented it to the VP and the team as QA's gate, not mine, and added a review-status gate in Jira showing where stories sat before QA. **R** A four-week cadence in six weeks and critical defects down 50%. QA's definition of done became the team's standard.

Land: −50% critical defects (record). **Don't say:** a promotion outcome. None recorded. **Drawn from:** R9.

3-level follow-up. L1 "Why QA?" → Their fear was a real design requirement. L2 "Did anyone push back?" → Developers worried about entry criteria slowing them, and the chart showed the opposite. L3 "Differently?" → Start with QA in week one.

Success and Scale Bring Broad Responsibility

AIQB: SUCCESS AND SCALE BRING BROAD RESPONSIBILITY Q1 **"Tell me about a time you worked on a project that had impact beyond your immediate client/customer/organization. How did you approach the potential downstream impact of this work? When in the course of the project did you start thinking about this impact, and what efforts did you make to manage this impact? What were the risks?"**

Opener: "Splitting customs ownership between two Flexport orgs changed who answered to shippers, brokers and ports. So I wrote the downstream effects into the agreement."

S Flexport, 2022: 15 work items for 2023 spanning shippers, external brokers, seaports and US Customs filings. **T** Assign owners without breaking anyone downstream. **A** I thought about downstream impact from the first table: each row named its user group (FlexGo operators, partners, the Flexport Customs team, external brokers) and whether it already existed in core. Risks: a licensed filing rebuilt outside customs, or a broker workflow orphaned. So filings stayed with qualified owners via APIs, EAD stayed with brokers offline until customs could integrate, and portfiling was placed where the seaport dependency lived. Both orgs took on shared cost-to-serve goals. **R** On Nov 3, 2022, the agreement was signed off with deferred items written down with triggers.

Land: 15 items; shared CtS goals. **Don't say:** a downstream metric. None recorded. **Drawn from:** R4.

3-level follow-up. L1 "Biggest risk?" → Regulated filings owned by a team that can't legally file them. L2 "Who was left worse off?" → Operators kept emailing EAD for now, which was written down, with a trigger. L3 "Differently?" → Run import items in parallel.

AIQB: SUCCESS AND SCALE BRING BROAD RESPONSIBILITY Q2 **"Tell me about a time when you decided to change a decision because of unintended consequences for your customers. What was the impact to your customers? What tradeoffs did you have to make? How did your new solution better serve your customers?"**

Opener: "My own availability rule was meant to protect customers from overselling. Its unintended consequence was that dotcom customers couldn't buy stock that was a day away."

S Sephora: my v1 ISM rule barred every channel from promising in-transit units. **T** Reverse my own decision safely. **A** Impact: fast movers were reliably one day from the building but unsellable on dotcom, and conversion was lost (Aging In-Transit and replenishment reports). Trade-off: some oversell exposure in exchange for sellable stock, bounded by a per-lane window from receiving history, an on-time floor and a kill switch. I took it through the same three signatories as a signed change. **R** Sellable units came back on qualifying lanes with oversell up zero, and the kill switch never fired (user anchor).

Land: oversell +0. **Don't say:** a lost-conversion dollar. **Drawn from:** F3 (fallback F1 if Ryan heard S4).

3-level follow-up. L1 "Why not reverse it fully?" → All-in-transit would have recreated oversell on lanes that run late. L2 "How did you size the window?" → Lane σ about 0.3 day gives about half a day at roughly 95% (user anchor). L3 "Lesson?" → Both sides of a rule get a number.

6 · New since this morning — six behavioral questions nobody has asked me yet

NEW

I checked these against both routers. The hiring manager (Tripathy) got CO Q8, CO Q5, Own Q3, I&S Q1, ARL Q1, L&BC Q4, HDB Q9, HSS Q4, HSS Q1, TB Q2, BfA Q1, Frug Q1, Frug Q5, ET Q2, ET Q6, ET Q1, DD Q3, DD Q2, DD Q4, DD Q1, Backbone Q1, Backbone Q4, DR Q3, EBE Q3 and BR Q5. Ryan (Hoerger) was routed by story, not by AIQB number: S19, S8, S8b, S8c, E7, S9, S20 and S6, with S4 as his failure answer. Section 5 above already uses Own Q1/Q2, I&S Q2/Q5, BfA Q4/Q8, TB Q1/Q4, Frug Q3/Q4 and DR Q1/Q2. The six below appear in none of those lists. They lean toward Ownership, Deliver Results, Invent & Simplify, Bias for Action, Think Big and Frugality, and every story is one the HM and Ryan did not hear.

#	AIQB QUESTION	STORY	WHY IT IS NEW FOR ROCKY
N1	Ownership Q4: sacrifice short-term gain for long-term value	R1 routing guide	Elementum transportation was not told to the HM or Ryan. Own Q4 is on no router.
N2	Deliver Results Q5: a goal you didn't think was achievable	R3 six sites, three waves	The HM's Deliver Results question was Q3. S7 at site grain was told to neither.
N3	Invent & Simplify Q6: a novel idea with a big impact	R4 Customs ↔ FFA split	The HM got I&S Q1. The Customs split is in no packet.
N4	Bias for Action Q5: move forward or gather more information	R5 production test account	The HM heard SV as an operating lens. This is the test-environment decision underneath it, so it's the same family from a different angle.
N5	Think Big Q6: improve a process that was working	R2 carrier bid	The HM got TB Q2. S17 was told to neither.
N6	Frugality Q2: completing a project with limited resources	R6 two programs, one team	The HM got Frug Q1 and Q5, from different stories. B3 is FREE.

N1 · Ownership — deferring the savings so the engine wouldn't tender on bad data

AIQB: OWNERSHIP Q4 **"Tell me about a time when you made a hard decision to sacrifice short term gain for something that would create long term value for the business. What was the outcome? Knowing what you know now, would you have done anything differently?"**

Opener: "I held a routing engine that was ready to switch on, and the first savings dollar waited weeks, because the data feeding it was 55% right. That wait is why the program closed at about eight million validated."

S Elementum, a client's Austria transportation site. The routing-guide engine could be configured. Reported data quality was about 40%, and my own SQL census of three years of shipments put it at about 55% true. The sponsor wanted savings now, and he wanted carriers penalized now.

T I owned the analysis, the rules design, the savings method and the scale gate. The short-term gain on the table was turning the engine on and booking early savings. The long-term value was a savings number Finance would sign and a template that could scale.

A I made one rule: the engine waits for the data. Quality had to reach 99% before scale, tracked weekly by defect class with an owner per class. I also gave up the easy headline number. I co-wrote the savings definition with Finance before the first claim: per shipment, contracted guide rate against the counterfactual paid rate, executed only, never "negotiated". I priced the wait for the sponsor: a few weeks of deferred savings, against one visibly wrong tender that would cost the program its credibility with the carriers and the site.

R Data quality reached 99% within a quarter (record). The Austria pilot went live inside a month at about 97% on-time measurement accuracy and about $500K a year (record). That pilot green-lit 25 European locations, which closed at about $8M of validated freight savings (record). Finance reused the method for later claims.

Land: ~55% true → 99% within a quarter, then ~$8M validated across 25 European locations (record). **Don't say:** a lane count, "one million", or a "negotiated" savings figure. Don't say the carriers were blameless either. The scorecard caught real misses later. **Drawn from:** R1. **LPs:** Ownership · Think Big · Insist on the Highest Standards.

TRADE-OFF I MADE

I traded weeks of early, un-auditable savings for a number Finance co-owned. It cost the sponsor's patience and a slower first dollar.

Would I do anything differently? I'd build the audit ledger during the Austria pilot, not alongside the first claims. The first CFO review would have been shorter.

L1 "How did you know the wait was worth it?" → The census showed that wrong-grain lanes and missing rates would route freight to the wrong carrier with confidence. One wrong tender in front of the carriers was the risk I priced.

L2 "Did the sponsor agree?" → Not at first. He wanted penalties now. His own three years of data settled it, so I didn't have to win an argument.

L3 "What did the wait actually cost?" → Weeks of deferred savings at one site. I don't have a dollar figure for the deferral in my record, so I describe it in weeks.

SAFE-SAY: "I deferred the first savings until data quality reached 99%, which took less than a quarter, and the program closed at about eight million validated across twenty-five European locations."

N2 · Deliver Results — the hostile site I didn't believe would make the average

AIQB: DELIVER RESULTS Q5 **"Give me an example of a mission or goal you didn't think was achievable. What was it and how did you help your team try to achieve it? Were you successful in the end? Looking back, would you have done anything differently?"**

Opener: "One of six sites ran a legacy system with flat-file exports and no change-data-capture. I didn't believe it could go live on the same template and the same three weeks as the others, so I said so and planned it last."

S Elementum, a client's manufacturing program. An external contract manufacturer published supply data from six site systems with six definitions of yield, lead time and order status. The goal was planning-grade supply visibility at all six sites (user anchor).

T I owned the ingest requirements, the per-site reconciliation gate, the wave plan and the weekly call with the contract manufacturer. None of the engineers reported to me. The part I didn't think was achievable was the legacy site on the same terms as the others.

A I told the team plainly that the legacy site would not hit the average, and I wrote that into the plan instead of hoping. I sequenced the rollout by risk. Wave 1 was the two cleanest high-volume sites, wave 2 was three sites on parameterized maps, and wave 3 was the legacy site with buffer. For that site we didn't wait for an upgrade it couldn't fund. I wrote the requirement for snapshot-diffing the flat files, and data engineering built it. The gate didn't move. No site went live until its reconciliation report matched the source. Overlapping revisions went to a quarantine queue for a human and were never auto-loaded.

R Six sites live in three waves over about five months (user anchor). The legacy site took about six weeks against a three-week average, and that was absorbed because it was planned last with buffer (user anchor). Zero overlapping revisions were auto-loaded (user anchor). So I was right that it wouldn't make the average, and wrong to think the goal itself was out of reach.

Land: six sites, three waves, about five months; hardest site about 6 weeks vs a 3-week average (user anchor, said as my program counts). **Don't say:** a reconciliation tolerance (none is recorded) or any dollar figure. **Drawn from:** R3. **LPs:** Deliver Results · Are Right, A Lot · Frugality.

TRADE-OFF I MADE

I gave up a single fast cutover for three gated waves. It cost calendar time, about five months, but one bad site could no longer poison trust in all six.

Looking back: I'd run the reconciliation report on a sample before writing the mapping spec, not after. The source's documentation was not the truth; the source system's own numbers were.

L1 "Why say it wasn't achievable instead of just pushing?" → A hidden slip on the last site would have looked like a program failure. A planned one was just a longer wave.

L2 "Why not force the site to upgrade?" → It had no budget and no timeline. Snapshot-diffing gave us change detection without asking them to fund anything.

L3 "What did you personally do on that site?" → I sequenced it, wrote the snapshot-diffing requirement and ran the weekly call where its reconciliation was read. Data engineering built the diff.

SAFE-SAY: "Six sites in three waves over about five months. The hardest site took about twice the average, and the plan already carried that. These are my program counts, and I claim no dollar figure."

N3 · Invent & Simplify — splitting ownership by who is licensed to file, not by who wants the work

AIQB: INVENT AND SIMPLIFY Q6 **"Tell me about a novel idea you had or decision you made that had a big impact on your business. What was novel about it?"**

Opener: "Two tech orgs were both building export customs. Instead of negotiating turf, we split the fifteen work items by one test: who is licensed to file, and who moves the cargo. Then we put APIs at the seams instead of shared code."

S Flexport, 2022. The Customs Platform and Freight Forwarding App (FFA) tech orgs overlapped on customs declaration work, most visibly AMS. The 2023 plan held 15 work items, 12 export and 3 import, with no agreed owner per item (record-from-docs).

T Get one named owner per work item, agreed by both orgs, before 2023 build planning. I was on the FF App program side VERIFY. I'm not on the meeting notes' attendee lists, so confirm my role first. If I can't, answer I&S Q6 with R2 instead. Neither org reported to the other.

A The novel part was the decision rule. Ownership followed qualification and operational ownership, not preference. Only licensed brokers can file AES and ISF, so those stayed with customs or ran through its APIs. Moving cargo onto a vessel is operations, so it sat with FFA. Every work item went into one table: user group, whether it exists in core, proposed owner, open question and engineering conclusion. We worked it row by row in two sessions, on October 26 and November 3, 2022. Where both sides touched an item, we wrote an integration contract instead of sharing code. For AMS, Customs Platform exposes create, amend, query and delete APIs, and FFA collects the filing data and watches for re-file triggers. The "not now" items were written down with a trigger: EAD stays offline with external brokers until customs can integrate, and China export documents may be revisited in 2025.

R Agreement on November 3, 2022: FFA owns every export work item except ISF filing, and AMS and AES run through Customs Platform APIs (record-from-docs). Customs Tech and FFA took shared cost-to-serve goals on AMS (record-from-docs). The impact was that 2023 export planning started with one owner per item and no duplicate build of licensed filing logic. I don't claim a downstream delivery metric, because the document records the agreement, not later results.

Land: 15 work items (12 export, 3 import), one owner each, agreed Nov 3, 2022 (record-from-docs). **Don't say:** "I wrote the proposal" unless confirmed, or any dollar or cycle-time impact. **Drawn from:** R4. **LPs:** Invent & Simplify · Earn Trust · Ownership.

TRADE-OFF I MADE

A split by qualification left ISF and AES open after the first session and kept EAD offline. I accepted a slower, partial answer over a fast split that would have duplicated licensed filing logic.

Failure / learning: The business owner of each regulated item wasn't in session one, so two items stayed open. Now every regulated item's business owner is on the first invite.

L1 "What's actually novel? That's just a RACI." → A RACI records a decision. This was the rule that made the decision, applied the same way to every row, so neither team could relitigate a row on preference.

L2 "Big impact — measured how?" → Every 2023 export item had one owner and one integration contract before build planning. That's what I can source. There's no later delivery metric in the document, so I don't claim one.

L3 "Who pushed back?" → Customs engineering was willing to own AES and ISF filing but needed their business team to decide, and preferred API-only integration. They were right, so we took the API route.

SAFE-SAY: "Fifteen work items for 2023, twelve export and three import. On November 3rd, 2022, we agreed that the app owns every export item except ISF filing, with AMS and AES through Customs Platform APIs. That's what the ownership proposal and its meeting notes record."

N4 · Bias for Action — a production test account instead of waiting a year for organic volume

AIQB: BIAS FOR ACTION Q5 **"Give me an example of when you had to make an important decision and had to decide between moving forward or gathering more information. What did you do? What was the outcome? What information is necessary for you to have before acting?"**

Opener: "We could wait for 4PL clients to grow organically until the end of the year and learn slowly, or test 3PL volume in production now. We moved forward with a client test account in production, 300 containers to start, and a kill-switch list in hand."

S Flexport Shipment Visibility, after launch. To find root causes of data inaccuracies we needed volume, and organic 4PL client growth would not supply it before the end of the year (record-from-docs, 3PL one-pager p1–2). The choice was between testing in staging and testing in production.

T As TPM, run the staging-versus-production decision with product and engineering, then make the chosen path safe for live clients.

A I ran a pros-and-cons analysis of staging versus production with product and engineering, and the team decided on a client test account in production (record-from-docs). Then I bounded the blast radius before anything ran. We started with 300 containers, Trans-Pacific lanes first and then all lanes, using Crux-only clients' data so 4PL and 3PL could be compared (one-pager p6–7). Testing was restricted to named client and trade-lane combinations. I built the list of switches to turn off, such as the Ocean Visibility subscription kill switch and the Trade Graph extract switches. The end-to-end monitoring from the launch stayed in place, and we reused the holiday support framework for blocker and critical issues (p5–6). The success metric was written before the test, as load-event tracing at each hop, along with what was not a goal: performance and cost-to-serve. Dependencies carried owners and dates. The trace-ID stories were due 4/2, and SOA ingestion was blocked on an Infosec ticket. The test was planned to start in the second week of April (p3–4).

R The decision and its controls are recorded in the one-pager (record-from-docs). The trace-ID stories were on track on the Visibility and Ocean teams, and the Flexport OS design doc was complete. The trace-ID change this test measured cut blocker-bug MTTR by about half (record-from-docs). The 3PL test's own final readout is not in my sources VERIFY, so I don't quote one.

Land: 300 containers, Trans-Pacific first, kill switches listed before go (record-from-docs). **Don't say:** a 3PL test accuracy result or "we found X% dropped". Neither is recorded. Don't say "I decided alone". The doc says the team concluded. **Drawn from:** R5. **LPs:** Bias for Action · Are Right, A Lot · Ownership.

"What information do you need before acting?" → Four things: is it reversible (the kill switches), is the blast radius bounded (named clients and lanes, 300 containers), is success written down (the tracing ratio), and is what's out of scope written down (performance and cost-to-serve). If those four exist, more information is a delay, not a safeguard.

TRADE-OFF I MADE

Production carries client risk that staging doesn't. I accepted it in exchange for real data volume now rather than at year end, and paid for it with switches, scoping and support coverage.

Failure / learning: Our own retrospective says monitoring came too late in the lifecycle and test estimates were too optimistic (Path to 4PL p2). I now put the monitors and the kill-switch list in the first sprint.

L1 "Why not staging?" → Staging couldn't give us real 3PL volume or the real data flowing between systems, and the whole point was to find where real events dropped.

L2 "What would have made you stop?" → Any disruption to a live client. The kill-switch list and the named client and lane scope existed so we could stop without a deploy.

L3 "Did it work?" → The decision and the controls are in writing, and the trace-ID change behind the test cut blocker MTTR by about half. I don't have the 3PL test's own final readout in my sources, so I won't invent one.

SAFE-SAY: "We chose a client test account in production over waiting for organic volume. We started with 300 containers on Trans-Pacific lanes, with the kill switches listed before we began. That's in my one-pager; the test's final readout isn't, so I don't quote one."

N5 · Think Big — the bid process worked; I questioned why it took six weeks

AIQB: THINK BIG Q6 **"Tell me about a time when you thought differently to improve a process that was working. What assumptions did you have to question? How did you evaluate if the change improved the process? Knowing what you know now, would you do anything differently?"**

Opener: "The carrier bid worked. It produced awards twice a year. It also took six weeks, and everyone assumed a better optimizer was the fix. I questioned that assumption by timing the work, and most of the six weeks was reconciliation."

S Elementum, a client's transportation team. A semi-annual carrier bid across hundreds of lanes and dozens of rate files took about six weeks a cycle (user anchor). It worked, so there was no burning platform, only a request for a better solver.

T I owned the requirements, the constraint rules and the parallel run. The award belonged to transportation and procurement.

A I questioned three assumptions. First, that it was an optimization problem. I sat through one full cycle and logged hours by activity, and the time went to reconciling lane names and mode codes. Second, that a better solver should be a black box. I required scenario comparison as a first-class output. Third, that six weeks was simply the cost of the bid. I specified a lane master, wrote every constraint as one readable rule and set a trust gate: the tool had to match the last two real awards within 5% before its output counted. We parallel-ran one region's live bid on both paths, then added a weekly rate-file refresh with a stale-data banner after 10 days.

R I evaluated it with the same team on the same kind of bid, against my own time audit of the previous cycle. The cycle went from about six weeks to about three, the pilot region finished three weeks early, and other regions adopted it without a mandate (all user anchor). No award dollars are claimed.

Land: about 6 weeks → about 3; 5% gate against the last two awards (user anchor). **Don't say:** award savings, "the optimizer saved $X", or "50% faster" as if audited. Say "about half". **Drawn from:** R2. **LPs:** Think Big · Dive Deep · Invent & Simplify.

TRADE-OFF I MADE

I spent one full bid cycle observing before building anything, and I didn't ship the solver everyone wanted. It cost some impatience from a team that wanted a tool.

Would I do anything differently? I'd bring procurement in at the time audit. They owned two award rules I had to retrofit before the second region.

L1 "Why touch a working process?" → It worked by consuming six weeks of analysts twice a year, and the hours were going to data hygiene, not decisions.

L2 "Why 5%?" → It had to beat the planners' trust in the last two awards. Below 5% mismatch they stopped re-keying, and above it they would have kept the spreadsheet running beside it.

L3 "How do you know it wasn't just a quiet cycle?" → Same team, same kind of bid, measured against my own audit of the previous cycle. These are program counts, not an audited report, so I say "about half".

SAFE-SAY: "About six weeks to about three, with the pilot region three weeks early. Those are my program counts. The award dollars belonged to transportation and procurement, so I don't claim them."

N6 · Frugality — two programs landed on one shared team with no new headcount

AIQB: FRUGALITY Q2 **"Describe a time when you had to get a project or initiative completed with limited resources. How did you approach the situation? What was the impact? Knowing what you know now, would you have done anything differently?"**

Opener: "Leadership pulled a go-live forward a month and moved half my engineers onto it. I didn't ask for headcount. I made one team's time count twice."

S Flexport, 2022. A strategic go-live was pulled forward a month onto engineers shared with my own program, with about $200K a month per DC of savings at stake (record). There was no added headcount, and the date wasn't mine to set.

T Land both programs, without the floor rejecting the compressed one, on the team I already had.

A The scarce resource was engineering attention, so I cut what was wasting it. One RAID log and one 45-minute daily forum for both programs, so nobody served two masters. One ruler for every issue: a true blocker, a non-blocker, or a requirements gap dressed as a blocker. Most "blockers" were reclassified within about a week. True blockers went through a two-pass war room, onsite and then offshore, with a written handoff, which gave round-the-clock coverage without anyone working round the clock. Escalations went to leadership as priced choices ("A costs this, B costs that"), so decisions came the same day. Go/no-go read the true-blocker burn-down against a floor agreed in advance.

R The compressed program landed inside four weeks and mine held its original date (record). The business adopted on time, protecting the roughly $200K a month per DC (record). The cost was the team's calendar, and I said so out loud.

Land: ~$200K/month per DC at stake; landed inside four weeks with no added headcount (record). Quote the monthly rate before the ~$1M-per-DC cumulative framing, if you use that at all. **Don't say:** "saved $1M" as a booked result. **Drawn from:** R6. **LPs:** Frugality · Deliver Results · Bias for Action.

If R6 was already told for Bias for Action: pivot to R3, where snapshot-diffing replaced a legacy upgrade the site couldn't fund, and give the six-sites, five-months frame.

TRADE-OFF I MADE

I didn't ask for headcount, which would have arrived after the date anyway. In exchange I spent my own time on a heavier operating rhythm and guarded the 45-minute forum so it didn't grow.

Would I do anything differently? I'd write the ten-step quick-reference guide for the DC floor first, not the week before cutover. Under compression, documentation dies first, and it was the cheapest fix I had.

L1 "Why not ask for contractors?" → They would have been onboarded after the date. The constraint was attention, not bodies.

L2 "Isn't relabeling blockers just optimism?" → No, it's triage. The proof was the true-blocker count burning down to the agreed floor, and go/no-go read that count.

L3 "What did it cost people?" → Two war-room passes a day for weeks. The onsite-offshore split with written handoffs is how nobody worked twenty-four hours.

SAFE-SAY: "About two hundred thousand dollars a month per DC was at stake. Both programs landed on one shared team with no new headcount: the compressed one inside four weeks, and mine on its original date."

7 · Questions to ask Rocky, source trace, VERIFY checklist NEW

Four questions to ask Rocky — infrastructure and program specific

These are new: none of them repeat a question planned for the HM or Ryan. Ask two, and keep two in reserve. Each one has a reason, what to listen for, and the story to bridge to if he opens the door. Don't claim knowledge of his org. Ask, then listen.

> ASK 1 · LAUNCH READINESS **"When a new building or a major retrofit goes live, what's the one readiness signal your team trusts most, and who owns the vendor dependencies on that critical path?"**
>
> **Why:** It's the question a launch program lives or dies on, and it shows I think in gates, not dates. **Listen for:** whether vendor dependencies sit on a risk register with triggers, or as tasks with dates. **Bridge:** F4. "I learned that one the hard way on a robotics retail track. A vendor dependency carried as a task slipped three weeks. Now it's a risk with a trigger date and an owner on both sides."

> ASK 2 · WHERE SCHEDULES SLIP **"Across your launch portfolio, where do schedules slip most often: construction and site readiness, equipment and vendor delivery, or systems integration and testing? How early does your mechanism catch it?"**
>
> **Why:** It tells me where the TPM in this role would earn their keep. **Listen for:** integration and test, which is my strongest ground, versus physical construction, where I'd be learning. **Bridge:** R5 or N4. "On a six-system platform, the slip hid in the seams between systems, so the first thing I'd build is a trace across them and a monitor per connection point."

> ASK 3 · THE WEEKLY READ **"In your weekly review for a launch program, does the room read curves or colors, and which input metric has a single-threaded owner who can move it?"**
>
> **Why:** It's a mechanisms question a Bar Raiser respects. **Listen for:** burn-down against a pre-agreed floor, owner per input, and how red is escalated. **Bridge:** R8. "On the UDC conversion the go-live gate was the issues-log burn-down, with every red carrying a name and a date, not a RAG color."

> ASK 4 · WHAT TRAVELS TO THE NEXT LAUNCH **"When one launch finishes, what actually travels to the next one: a playbook, a checklist, people, or tooling? Who owns keeping it current?"**
>
> **Why:** It's the Think Big / scale question, and it tells me if the role builds templates or fights fires. **Listen for:** whether lessons become standing controls or stay in retrospectives. **Bridge:** R1. "I designed one site's pilot as the template for twenty-five locations. A new site cost one rules file and one data-quality cycle (user anchor)."

Source trace — every number in R1–R9, F1–F4 and N1–N6

Basis labels: **record** is in Apple v11 or the resume. **record-from-docs** is in a primary document in /tmp/sources. **user anchor** is in GFiber v8 only, with no primary support, so say it as "my program count". **Match** is checked against NUMBERS-RECON canon v2 where it has a row.

Numbers that differed between sources, and how I resolved them

ITEM	WHAT DIFFERED	RESOLUTION USED IN THIS BANK
S10 DQ timeline	Apple F2 says 99% in two months. Master canon says about three, never two.	"Within a quarter", which is true under both. Exact month count is VERIFY.
SV 2–4 hours	Recon §3 paraphrases it as troubleshooting cut *to* 2–4 hrs. The one-pager says the missing ID *caused* 2–4 hrs.	Primary doc wins: 2–4 hrs was the **before**, and the after is "MTTR about half".
B3 value	~$200K a month per DC vs "~$1M per DC protected" in the same chapter.	Rate first. The $1M is used only as cumulative framing and never as booked savings.
M1 $6M / $8M	Apple uses $8M both as revenue at risk and as sales protected.	Recon wording: "$6M on the line … about $8M of the day's sales protected."
Issues-log share	52.8% (Apple) vs 52.75% (recomputed).	Said as "just over half the book".
UDC duration	Apple carries both "fifteen months" and "fourteen months". The log spans 2024-03-17 → 2025-10-01.	R8 says "836 rows from March 2024 to October 2025" and gives no month count.
G2 devices	The Apple source-doc title carries a device count, but canon says "hundreds".	"Hundreds of RF devices" only.
S7 / S17 / S4 figures	GFiber v8 only, with no Apple or primary support.	Labeled user anchor every time. S7 is told at site grain, with no component-level framing.

VERIFY checklist — confirm before Friday 10:00, or say the safe sentence

ITEM	WHERE	SAFE SENTENCE IF NOT CONFIRMED
Rajesh's role in the Customs ↔ FFA split	R4, N3, ET Q5, BR Q1	"The ownership proposal and its meeting notes record the agreement. I'll describe what the document says rather than claim authorship." If the role can't be confirmed, drop R4 and use R2.
Root cause of the Locus RTL vendor slip	F4	"The slip came from a vendor-and-integration dependency. The failure I own is that I carried it as a task, not a risk."
Feedback quotes about the B3 team experience	EBE Q5	"I don't have their words written down, so I'll tell you what I did: one 45-minute forum and nobody working 24 hours."
S10: two months or three to reach 99%	R1, N1, CO Q6	"Within a quarter."
S7 / S17 / S4 figures (user anchors)	R2, R3, F3, N2, N5	"Those are my program counts, not a published report, so I say 'about'."
3PL production-test outcome	N4	"The decision and the controls are in my one-pager. The test's final readout isn't in my notes, so I won't quote one."
B3 $1M cumulative window	R6, N6, BfA Q8	"About two hundred thousand a month per DC. That's the number I'd defend cold."
Did Ryan already hear S4 as the failure answer?	F3, ARL Q4, BR Q2	If yes, lead with F1 or F4 and offer S4 only as "a different angle: the signed-change mechanics".

ITEM	WHERE	SAFE SENTENCE IF NOT CONFIRMED
Did Josyula's packet take D3 or G3?	R9, F2	Tell the Rocky angle only: R9 as Hire & Develop, F2 as the planning control.

Spoken guardrails, one last time: no spoken multipliers. Say 9.7× or "7 to 68". "Sixty-six cents to three cents, about 95%". "About $5M avoided" once at most. "A thousand lanes asked; 597 first". The $2.5M and $1.5M figures only ever with their noun. "Six sites", at finished-goods or site grain. RF devices: "hundreds". "About a dozen systems". The S14 $10M is not savings. The S16 figure over $100K was priced, not saved. Walmart S19–S21 and E1–E12 are design cases. Every number carries its basis word.

Amazon NACF Supply Chain loop — Packet 3 add-on: Rocky Goforth — the S/4 HANA ↔ ISM program end to end

Amazon — Senior Supply Chain Manager, NACF Supply Chain (L6)

Rocky Goforth

Senior Manager, Infrastructure — NACF

Thursday, October 30, 2026 · 10:00 am PDT · 55-minute video interview

COMPANION TO PACKET 3 (NINE SEPHORA UDC PRIMARIES). THIS ADD-ON CARRIES THE THREE END-TO-END S/4 STORIES PACKET 3 DOES NOT: THE ONE-UNIT-TO-PUBLISHED-AFS WALK, THE INFRASTRUCTURE VIEW OF THE SAME PROGRAM, AND SHIPPED-NOT-BILLED TO ONE FINANCIAL ON-HAND.

Why this add-on exists. Rocky knows how available-for-sale, Financial On-Hand and the reserve buckets are calculated. A story that says "I unified availability" without the arithmetic will be probed to the definition. So every term below has one exact definition, one system of record, one grain, and every formula is shown symbolic → substituted → computed on a single SKU at the Utah DC across a full day of physical events. **Three new primaries:** S1-R (end to end — one physical unit to the AFS the order system publishes), S1-R-infra (physical truth vs system truth — the infrastructure seat), S3-R (Shipped-Not-Billed and the one Financial On-Hand). Every number is the master canon's value with its basis label; where canon is ambiguous the sources are quoted verbatim and the safe sentence is given instead of a guess.

LP focus — my guess, not confirmed: Dive Deep · Insist on the Highest Standards · Earn Trust · Invent and Simplify. The definitions card and the calculation walk are built for a Dive Deep interviewer; the infrastructure story is built for the title. No interviewer biography is asserted — title-based inference only.

Canon: amazon/amazon-l6-scm-master-packet.html (S1, S3, S18, §4 ledger) and /tmp/sources/NUMBERS-RECON.md §3 CANON v2. Definitions and formulas trace to the GFiber v8 master (the original ISM chapter: System & data map p36–40, AFS reports p41–45, S3 p62–64) which the Amazon master was transformed from; dates and failure beats to Apple PM III v11 (C1 p22, C2 p24, D1–D2 p28–31, G2 p44–45). Basis labels: record · record-from-docs · user anchor · modeled · illustrative. This file is standalone and does not modify Packet 3.

How to use this add-on — and the 1-page cram sheet NEW

How to use. Read the Definitions card once, slowly. Then read S1-R's calculation walk (Tables W1–W4) with a pen: every row is formula → substitution → value and the Python recompute that built this file asserts every one. S1-R is the story to tell when Rocky asks "walk me through how availability actually got calculated." S1-R-infra is the same program from his seat — scan to WMS to S/4 posting, what breaks when a device or feed is late, the cutover night. S3-R is the Finance leg — Shipped-Not-Billed, de-aggregation to the cent, one Financial On-Hand. Packet 3's U1 (bucket matrix), U3 (merch reserve), U5 (runbook) and U6 (Negative AFS) are the deep dives behind single steps of the walk; this add-on is the arc that connects them.

> **THE ONE DEFINITION AND THE ONE FORMULA — SAY THESE COLD**
>
> **Definition.** "Available-for-sale is the one number a channel may still promise for a SKU at a node. It is not S/4's stock figure. S/4 owns the physical book — unrestricted stock per SKU, plant and storage location, which we called Available. ISM takes that book, applies the lower-of-two rule against the warehouse floor, subtracts everything committed or sold but not yet posted, and publishes AFS per SKU, node and channel. The order system reads it and never computes its own."
>
> **Formula.** "Basis is the lower of S/4 Available and the WMS on-hand; AFS equals Basis minus Picking Reserve minus Ecom Pick minus Ecom Pack minus Shipped-Not-Billed. Merchandise Reserve and Lost-and-Found sit outside Available by construction, so they are never subtracted twice. On the worked SKU: Basis is the lower of 1,000 and 980, so 980; buckets 200 plus 120 plus 60 plus 40 are 420; AFS is 560."
>
> **Financial On-Hand (the honest sentence).** "Financial On-Hand is Finance's number — Available plus Merchandise Reserve plus Lost-and-Found — with Shipped-Not-Billed carried as its own reconciling column so Finance sees what has left the floor but not yet posted; it ties to MB5L at month-end at tolerance zero." FOH expansion: canon says Financial On-Hand; "free on hand" is not in any source — see Verify #1

The three stories in order, the single number each lands

ORDER	STORY	TELL IT WHEN	THE NUMBER TO LAND	BASIS
1	**S1-R** — one unit to published AFS	"How was availability actually calculated?" · Dive Deep · Invent and Simplify	AFS = 980 − 420 = 560; drift 0 at T+1; zero oversell incidents through two go-lives	illustrative walk (canon family) · record
2	**S1-R-infra** — physical truth vs system truth	"What happens when a scan is late or a device fails?" · Insist on the Highest Standards · Are Right, A Lot	WMS feed ≤15 min or publish suppressed; republish p95 <60 s; 343 tasks ≈ 815 h; triggers armed twice, never fired; training +1.5 weeks, date held	record design · record
3	**S3-R** — SNB and one Financial On-Hand	"How did Finance and Supply agree on on-hand?" · Earn Trust · Customer Obsession	FOH truths 2 → 1; Σ per-line COGS ties to the cent ($300.00 = 75 + 50 + 100 + 25 + 50); ≈$0.6M/yr modeled	user anchor · record mechanism · modeled

Three sentences to open with

> "At Sephora two inventory books — the legacy MCS and S/4 HANA — each published their own 'available', and every org defined the word differently. I owned the signed definition and the one engine that publishes it."
>
> "I can walk one unit from the dock to the number the order system reads, bucket by bucket, with the formula at each step — and tell you which report catches it when a step is late."
>
> "The record is zero customer-facing oversell incidents through the January and May go-lives, drift at tolerance zero at T+1, and Finance closing on the same on-hand Operations reads."

The five numbers never to get wrong

1 · **AFS = 980 − (200 + 120 + 60 + 40) = 560** — the canon worked family; flip the floor to 1,020 and Basis is 1,000 → AFS 580, never 600 (illustrative).

2 · **Drift tolerance 0** — ISM S4_Avail − MB52 per SKU × SLoc at the daily watermark; non-zero is a Sev, not a planning variance (record design).

3 · **"January planning go-live, then May execution"** — PO-creation Jan 2025 → combined May 2025 (record, Apple C1 p22). Never "the March go-live."

4 · **$2.5M a year** — the S1 noun: $1M MCS support retired (user anchor) + ≈$1.5M modeled. Always split; never a bare "$2.5M" (it is also S18's monthly slip and S14's order value).

5 · **"Hundreds" of RF devices; training slipped 1.5 weeks; go-live date held** (record, Apple G2). Never "100 of 400"; never a cost multiplier.

Safe-wording rules in force (addendum §D). "About a dozen impacted systems" · "the umbrella program's 836-row log" (it is UDC's, never ISM's) · finished-goods grain only · cutover 343 tasks ≈ 815 task-hours · "$1.5M" and "$2.5M" always with their noun · never a cost multiplier on the RF fallback · FSD dates (3/5, 5/16, 6/5/25) are user anchor — say "signed in the first week of June" if unsure.

Definitions card — built only from the sources NEW

One row per term. "Exact definition" quotes or tightly paraphrases the GFiber v8 ISM chapter (the original definitions the Amazon master S1/S3 were cut from) and the Amazon master; the source column names the page. Where two source passages differ the row says CONFLICT and the Verify list carries the safe sentence. Grain column: N = per node (plant/SLoc or store), C = per channel.

TERM	EXACT DEFINITION (SOURCE WORDING)	SYSTEM OF RECORD	CALCULATED WHEN / WHERE	N / C
Available (S4_Avail)	"S/4 owns the physical book: unrestricted stock per SKU × plant × storage location, which we called Available." MARD-LABST (unrestricted); QI/blocked (INSME/SPEME) are not Available.	SAP S/4HANA MM-IM (MARD / MATDOC; MB52 view)	Posted on every material document; ISM holds a copy: daily MB52 snapshot + MSEG 101/311/601/701/702 lines as real-time events	**N (SKU × WERKS × LGORT); not C**
WMS_OnHand (the floor)	"on-hand by item × location × status … Sum pickable statuses only; damaged/hold excluded"; for OOB the snapshot includes "allocated/picked/packed units (presence, not status), with shipped-not-posted netted via SNB."	BlueYonder WMS	≤15-min feed, key item × whse × as-of; late >15 min ⇒ publish suppressed for that node, last-good AFS held and flagged	**N (DC only; stores have no WMS floor)**
OOB (out-of-balance)	"OOB_in = S4_Avail_in − WMS_OnHand_in (+ = book above floor, − = floor above book)"; "held constant intraday; every closed row carries a cause code (found / confirmed missing → Lost/Found)."	ISM (R6 job, inputs S/4 + WMS)	Daily, both snapshots at the same cutoff — "the one report where a cutoff mismatch manufactures a phantom OOB the size of the day's shipments"	**N**
Basis	"Basis_in = min(S4_Avail_in, WMS_OnHand_in) — a positive OOB reduces supply; a negative OOB is never promised until S/4 books it." Store node: Basis = S4_Avail (no WMS floor).	ISM AFS engine	Recomputed on every event that moves either input	**N**
PickRes (Picking Reserve)	Retail / store-fulfilment commitment: "Σ open STO = PickRes, tolerance 0 (record)"; "PickRes from the STO feed." *Note:* the GFiber mapping row also reads "Commit → Picking Reserve; pick confirm → Ecom Pick; pack confirm → Ecom Pack" — CONFLICT on where a web-order commit lands; R4 (record) is used here. Returns/RTV: "returns post to unrestricted (653/655) and RTV runs as an STO — so they are excluded" from the S1 record.	ISM reserve_ledger (source: S/4 STO EKKO/EKPO type UB; GI via 641)	+ at STO creation; − at 641 goods issue; real-time event, key per STO line	**N (SKU × supplying plant)**
EcomPick	Open e-commerce order units committed/picked, not yet packed: "Σ open orders = EcomPick (+ EcomPack at stores), tolerance 0 (pattern)."	ISM reserve_ledger (source: OMS order-line events)	+ on order commit; moves to EcomPack on pack confirm; cancel reverses and must reference its original; key OMS × OrderLine × line × event_type	**N; published AFS is N × C**
EcomPack	Packed, not yet ship-confirmed e-commerce units. *Note:* R3 says "a Pack balance at a DC must be 0 by definition" while the canon walk carries Ecom Pack 60 at the DC — CONFLICT; the walk follows the canon figures and treats Pack as the packed-not-shipped window.	ISM reserve_ledger (source: OMS pack confirm)	+ on pack confirm; − on ship confirm (moves to SNB)	**N**
SNB (Shipped-Not-Billed)	"SNB_in(t) = Σ sold-or-shipped-not-posted units − Σ matched-posting units. Increment on POS flash sale, OMS omni pending sale, WMS ship confirm; decrement only on a matched S/4 aggregate posting." "SNB ≥ 0 always (a negative attempt is rejected and alerted)."	ISM snb_ledger; S/4 SD/FI owns the posting (Aggregation#, qty, COGS)	+ real-time (Kafka POS line; ship confirm); − on match by Aggregation# ↔ header ↔ lines; nightly for stores, intraday batches at DCs	**N (store or DC where the unit left)**

TERM	EXACT DEFINITION (SOURCE WORDING)	SYSTEM OF RECORD	CALCULATED WHEN / WHERE	N / C
MerchRes (Merchandise Reserve)	"QI/blocked/on-hold → Merch Reserve"; "Merchandise Reserve and Lost/Found are outside S4_Avail by construction, so they never appear in the subtraction — no double-subtract path exists." Visible in FOH and screens, never promisable.	S/4 (stock type) + FRAME holds; ISM displays	Nightly + HUD rollover 00:00 local; Σ reserves ≤ Basis asserted	**N (store: no MerchRes)**
LostFound	"PI differences (701/702) → Lost/Found until cleared."	S/4 (701/702 documents); ISM bucket	On physical-inventory posting; cleared by IC with cause code	**N**
AFS (Available-for-Sale)	"AFS_in = Basis_in − PickRes_in − EcomPick_in − EcomPack_in − SNB_in, where every subtrahend is a committed-or-sold-not-posted bucket." "If AFS < 0: publish 0, write row" (R7). "Sanity: AFS ≤ Basis ≤ both books."	ISM AFS engine — the only publisher; "OMS / dotcom / stores read AFS, never compute"	Event → republish p95 < 60 s; key MATNR × node × channel × version; publish gate: Active Assortment flag per channel	**N × C (published per SKU × node × channel)**
FOH (Financial On-Hand)	S1 (DC): "FOH_n = Avail_n + MerchRes_n + LostFound_n (physical truth for Finance; AFS is the promising truth for channels)"; R11: "(store: no MerchRes)". S3 walkthrough: "available plus merchandise reserve plus lost-and-found plus SNB." CONFLICT on the SNB term — see Verify #1/#2. No source expands FOH as "free on hand."	Published by ISM; S/4 owns value (MBEW-VERPR / WAC); ties to MB5L	Daily after the match cycle; month-end tie to MB5L, "tolerance 0 units; a value difference is a WAC ownership question (S/4 owns it, ISM only displays it)"	**N (SKU × node × day); not C**
Drift (T+1 reconciliation)	"Drift_in = ISM.S4_Avail_in − MB52_in per SKU × SLoc at the daily snapshot; Drift ≠ 0 is a Sev, not a planning variance." Test B identity: "ISM_S4_Avail = (AFS − P) + PickRes + EcomPick + EcomPack + SNB + max(OOB, 0)."	ISM R2 job vs S/4 MB52 / MB5B re-cut by posting time	Daily at a declared watermark; both sides read at the same watermark; tolerance 0	**N**
Negative AFS / AFS Correction	"Negative AFS is a report, not a value channels read"; "clean at T+1 was a go-live exit bar." Every AFS-changing act has "a screen, a role and an audit row."	ISM screens; owners: Negative AFS → Inventory Control + Internal Audit + Finance; AFS Correction → ISM app team	At publish; cleared by cause class (cardinality / latency / override)	**N × C**
Aggregate posting / de-aggregation	"Aggregate posting P with total qty q_P and total COGS C_P; line i with q_i: COGS_i = C_P × q_i / q_P, with Σq_i = q_P and ΣCOGS_i = C_P (allocation is exact; last line absorbs rounding so the sum ties to the cent)." Match rule: "park unless Σ q_i = q_P; >24 h flag, >48 h Sev."	S/4 SD/FI posts; ISM matcher de-aggregates; EDW receives per-line COGS with Aggregation# lineage	Each match cycle; unmatched-aging report (R8) owned by Inventory Accounting	**N × sales-event line**
Publish switch (cutover)	"no SKU may be published from two locations at any instant — zero on the old publish, then 100% on the new" (R10). Rollback: "sync < 99% for four consecutive hours or order-flow p95 > 2× budget for one hour, consumers revert to the prior publish."	ISM publisher; runbook step 4 zero-then-publish	Cutover night, inside a transfer freeze; "armed for both go-lives, never fired"	**N × C**

Sources for every row: GFiber_MASTER_Packet_v8 p36–40 (system map, data-flow table, Math, Data mapping) and p41–45 (R1–R11, "what typically goes wrong"); p62–64 (S3 Math and walkthrough); Amazon master S1/S3 (cb91 p20–21 carry the same formulas verbatim). Movement types 101/311/601/641/653/701/702 and tables MARD/MSEG/MATDOC/MB52/MB5B/MB5L/MBEW are standard SAP named in those pages.

Router addendum — Leadership Principles → these three stories (real AIQB wordings) NEW

Supplements Packet 3's Question → Story Router. Use this grid when the question is about S/4, ISM, availability, Finance tie-out or cutover infrastructure. Question wordings are quoted from the Amazon Interview Question Bank and cited "AIQB: LP Q#".

LP	AIQB QUESTION (VERBATIM)	PRIMARY · ANGLE	BACKUP	15-SECOND OPENER	NUMBER TO LAND
Dive Deep	*"Tell me about a time when you were trying to understand a complex problem on your team and you had to dig into the details to figure it out." (AIQB: Dive Deep Q1)*	S1-R · calculation walk	Packet 3 U6	"Two books each said 'available' and meant different things. I walked one SKU through a day, bucket by bucket, until every unit sat in exactly one place."	**980 − 420 = 560**
Invent and Simplify	*"Give me an example of a complex problem you solved with a simple solution. What made the problem complex?" (AIQB: Invent and Simplify Q1)*	S1-R · design angle	S3-R	"The simple solution was one identity: Basis minus four buckets, one publisher, consumers never compute. The complexity was five feeds at five cadences."	**1 published AFS per SKU × node × channel**
Insist on the Highest Standards	*"Describe a time when you refused to compromise your standards around quality/customer service, etc." (AIQB: Insist on the Highest Standards Q1)*	S1-R-infra · tolerance 0, publish suppression	Packet 3 S18	"Drift tolerance was zero, and when the floor feed went stale we held the last good number and flagged the node rather than compute on a lie."	**≤15 min feed · drift 0 · negatives clean at T+1**
Are Right, A Lot	*"We don't always make the right decision all the time. Tell me about a time when you made a bad decision." (AIQB: Are Right, A Lot Q4)*	S1-R-infra · RF-device script (Apple G2)	master S4	"I scored a device task by effort, not impact; the script failed on new hardware and training slipped a week and a half — the date held."	**+1.5 weeks; date held**
Bias for Action	*"Tell me about a time when you had to gather information and respond immediately to a situation." (AIQB: Bias for Action Q4)*	S1-R-infra · stale feed / negative at cutover	Packet 3 U5	"On the cutover wall a node's floor feed aged past fifteen minutes; the engine had already suppressed publish — we re-read, not re-promised."	**last-good AFS held; 60 s republish**
Earn Trust	*"Tell me about a time when your team's goals were out of alignment with another team you relied on in order to meet your goal." (AIQB: Earn Trust Q5)*	S3-R · Finance keeps its own reconciliation	S1-R	"Finance said 'we keep our own reconciliation.' I showed them the same on-hand arriving from the physical side first, and gave them the aging report to own."	**FOH truths 2 → 1**
Customer Obsession	*"Tell me about a time when you had to balance the needs of the customer with the needs of the business." (AIQB: Customer Obsession Q8)*	S3-R · decrement at sale, not at posting	S1-R	"A store sale S/4 would not see until the nightly aggregate was a unit dotcom could still promise. I moved the decrement to the moment of sale."	**phantom window → 0; late line = −2, never +2**
Ownership	*"Describe a time when you had to transition a project you owned to a new owner." (AIQB: Ownership Q5)*	S3-R · Finance owns the aging report	Packet 3 U6	"The product was not the matcher; it was Inventory Accounting running the unmatched-aging report without me."	**>24 h flag · >48 h Sev · match ≥99.5% design target**
Deliver Results	*"Tell me about a time when you had significant, unanticipated obstacles to overcome in achieving a key goal." (AIQB: Deliver Results Q2)*	S1-R-infra · cutover night	Packet 3 U5	"343 tasks, about 815 hours, one irreversible instant — zero then publish — with rollback triggers armed twice and never fired."	**343 / ≈815 h / never fired**
Have Backbone; Disagree and Commit	*"Describe a time when you took an unpopular stance in a meeting with peers and your leader." (AIQB: Have Backbone Q2)*	S1-R · lower-of-two (surplus never promised)	Packet 3 U3	"Merchandising wanted the 20-unit floor surplus promised. I said no: a negative OOB is never promised until S/4 books it — AFS 580, not 600."	**580, not 600**

Non-LP prompts: "explain a formula you own" → S1-R Table W1; "a time Finance disagreed with ops" → S3-R; "a go-live gone wrong" → S1-R-infra (device script); "how do you know two systems agree" → S1-R Table W4 (Test A / Test B).

The stories — end to end, definitions first, canon numbers

Three primaries on the Sephora S/4 HANA ↔ ISM program. Each: 60-second pitch → Situation/Task → Action in five gated phases → Results → L6 evidence → five facets and probing → the calculation walk and four-table math → behavioral pack, angle cards, trap drills, 20-second version, NACF bridge and the safe-say box. The worked SKU is illustrative and uses the canon 1,000 / 980 / 560 family so it matches Packet 3's U1, U3 and U6.

S1-R — End to end: from one physical unit at the Utah DC to the AFS the order system publishes — two books, one signed definition, one engine, one identity that must hold at T+1 with tolerance zero NEW

LPs this story serves here: Dive Deep (primary — the calculation walk) · Invent and Simplify (one identity, one publisher) · Have Backbone; Disagree and Commit (the surplus is never promised) · Earn Trust (three orgs signed one definition)
Process family: Plan / Deliver — inventory availability definition and control: bucket design, system of record per bucket, publish contract, reconciliation

Honesty label. Record: two books (MCS and S/4) with "available" defined differently by different orgs; recurring oversell → zero customer-facing incidents through both go-lives; the FSD-signed policy (lower-of-two basis, AFS/FOH equations, real-time decrement contract, daily ISM-vs-MB52 reconciliation at tolerance zero); PO-creation go-live January 2025 → combined go-live May 2025; E2E chain Inbound 11/22 · Dotcom 12/20 · Retail 1/30; 60+ stakeholders; about a dozen impacted systems. User anchor (GFiber v8 only — confirm): FSD v1.1 3/5/25 → v1.2 5/16/25 → signed 6/5/25; three signing orgs; $1M MCS support retired. Modeled: ≈$1.5M (oversell $0.9M + reconciliation $0.33M + change premium $0.3M) on an illustrative 30M-order base. Illustrative: every unit count in the walk (SKU 12345 × node 801, the 240-unit receipt, the 700-unit damage, the −30). I wrote the definitions, the identity, the keys, the tolerance and the owner map; the S/4 and ISM engineers built the extracts, the engine and the screens; Inventory Control, Inventory Accounting and the ISM app team run the controls.

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH

Dive Deep. I can walk one unit from the 101 receipt to the number the order system reads, name the bucket it sits in at every minute, and name the report that catches it when a step is late.

Invent and Simplify. Five feeds at five cadences collapsed into one identity — Basis minus four buckets — with one publisher and consumers that never compute.

Have Backbone; Disagree and Commit. I refused to promise the floor surplus: a negative OOB is never promised until S/4 books it — 580, not 600.

Earn Trust. Three orgs that defined "available" three ways signed one table; Finance reads the same on-hand Operations reads.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. Sephora ran two inventory books — the legacy MCS and S/4 HANA — and every org meant something different by "available": Finance meant the posted book, dotcom meant what it could promise, the DC meant what it could pick. The result was recurring oversell — units promised that the floor could not back — and a negative available-to-sell that surfaced as an order that could not ship. **Task.** Own one signed definition of available, one engine that publishes it, and the controls that prove the two books agree every day. **Action.** I defined the buckets and the system of record for each: S/4 owns the physical book — unrestricted stock per SKU, plant and storage location; the WMS owns the floor count; the OMS owns what is committed, picked and packed; the POS owns what a store sold that S/4 will not see until the nightly aggregate. ISM takes the lower of book and floor as the basis, subtracts Picking Reserve, Ecom Pick, Ecom Pack and Shipped-Not-Billed, and publishes one AFS per SKU, node and channel; the order system reads it and never computes its own. Reconciliation is daily, ISM's copy of available against MB52, tolerance zero — a non-zero drift is a Sev, not a planning variance. Three orgs signed it in the FSD; January was the planning go-live, May the execution go-live. **Result.** Primary metric: customer-facing oversell incidents from recurring to zero through both go-lives, negatives clean at T+1 at cutover, drift at zero; about $2.5M a year — $1M of MCS support retired, my program number, and roughly $1.5M modeled, inputs on request.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — Two books, one word. MCS and S/4 each published an "available"; Finance, Merchandising, dotcom, the stores and the DC each defined it differently; the stores' sales reached S/4 only as a nightly aggregate, the OMS committed units S/4 could not see, and the WMS floor disagreed with the book by whatever had moved since the last snapshot. Oversell was recurring — no count in the record — and reconciliation was argument.

T — Write the one definition of available that every org would sign; assign one system of record per bucket; make one engine publish it per SKU × node × channel; and prove daily, at tolerance zero, that the engine's copy of the book equals the book.

Baselines on the table: 2 books · "available" defined per org · oversell recurring (record, no count) · reconciliation by hand (≈4 FTE, benchmark) · 60+ stakeholders, about a dozen impacted systems (record) · a 30M-order illustrative base for the model.

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery (3/29 → 4/30)** — bucket inventory: every place a unit could sit, who owned it, which document created it; the five feeds and their cadences (S/4 documents, WMS ≤15 min, OMS real-time, POS real-time, S/4 aggregate nightly). *Exit bar:* every bucket has exactly one owning system; open questions dated.
- **Plan & Design (5/15 → 8/14; ISM FSD v1.1 3/5/25 → v1.2 5/16/25 → signed 6/5/25 — user anchor)** — the lower-of-two basis; AFS and FOH equations; the real-time decrement contract (event → one bucket delta; idempotency key per event; a reversal must reference its original); the daily drift check at tolerance zero; the control-owner map. *Exit bar:* the sellable table signed by the business; every AFS-changing act has a screen, a role and an audit row.
- **Build & Test (Aug → Jan/Apr)** — the node × channel × bucket-transition matrix as the regression asset (Packet 3 U1); the replay test (the day replayed into a shadow ledger equals production); E2E chain Inbound 11/22 · Dotcom 12/20 · Retail 1/30. *Exit bar:* Blocker + Critical open = 0; three E2E dates green.
- **Cutover & Go-Live (January planning go-live; May execution go-live)** — R10 cutover balance sheet (MCS closing · S/4 opening MB52 · ISM seed, Σ per bucket equal); clear negatives first; zero-then-publish so no SKU is ever published from two locations; OMS re-pointed to read ISM AFS; rollback triggers armed. *Exit bar:* negatives clean at T+1; no SKU with two published AFS values; drift 0 on the first morning.
- **Hypercare / Close (Jun → Jul)** — I read the drift report every morning until the control owners read it without me; MCS retired (no live arrow). *Exit bar:* drift = 0 SKUs on consecutive days; owners running R2, R6, R7, R8 without me.

Influence and ownership. Mine: the definitions, the identity, the keys, the tolerance, the owner map, the go/no-go recommendation. The S/4 and ISM engineers built the extracts, the engine and the screens; Inventory Control owns drift and OOB; Inventory Accounting owns the settlement match; the ISM app team owns replay, quarantine and AFS Correction.

> **Designed the process; others own it now.** The daily drift report, the Negative AFS and AFS Correction screens, and the unmatched-aging report are run by their owners inside the monthly release train. **Trade-off put to leadership:** an asymmetric basis — surplus never promised, so visible undersell and more investigations — against oversell as a customer defect. Leadership accepted the undersell.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY

- **$** — about $2.5M a year: $1M MCS support retired (user anchor) + ≈$1.5M modeled (oversell 30,000,000 × 0.10% × $30 = $900,000; reconciliation 3 × $110,000 = $330,000; change premium 40 × 60 h × $125 = $300,000). Never a bare "$2.5M".
- **#** — 2 books → 1 published AFS per SKU × node × channel; 4 subtrahend buckets; 11 reports (R1–R11) each with a grain, a watermark, a tolerance and an owner; three signing orgs (user anchor).
- **%** — drift tolerance 0%; design: feed completeness ≥99.9%; the model's 0.10% oversell rate is a benchmark, not a measurement.
- **Time** — January planning go-live → May execution go-live (record); event → republish p95 < 60 s; WMS feed ≤ 15 min; negatives clean at T+1.
- **Customer** — customer-facing oversell incidents recurring → zero through both go-lives (record).
- **Quality** — every booked unit sits in exactly one bucket: ISM_S4_Avail = (AFS − P) + PickRes + EcomPick + EcomPack + SNB + max(OOB, 0), asserted daily (record design).

L6 LEVEL EVIDENCE — every line is this story's record or labeled model, no new canon numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	"Available" meant three things to three orgs; I wrote the one table and got it signed.
Scope & influence	60+ stakeholders across about a dozen impacted systems; none reported to me; three orgs signed.
Execution trade-off + mechanism others own	Asymmetric basis (undersell accepted) against oversell; the mechanism others own: R1–R11 with named owners.
Impact	Oversell recurring → zero through two go-lives; MCS retired; Finance and Operations on one number.
Process improvement	Reconciliation moved from argument to a daily identity at tolerance zero; a new node or channel is a matrix row, not a project.
Complexity & consensus	Five feeds at five cadences; one identity; one publisher; signed FSD.
Root cause at scale	Every break is attributable: timing (posting time > watermark), duplicate (transition log), true drift (IC with cause code).

PROBING — FIVE FACETS, THEN THE HARDEST FOLLOW-UPS NEW

THE FIVE FACETS — WHERE EACH ONE LIVES IN THIS STORY

1 · Data analysis. Grain: SKU × node (plant/SLoc) × channel × as-of timestamp. Data: MARD-LABST unrestricted per SKU × WERKS × LGORT (daily MB52 snapshot); MSEG lines 101/311/601/641/701/702 as events keyed MBLNR × ZEILE; WMS on-hand by item × location × status (≤15 min); OMS order-line events keyed OMS × OrderLine × line × event_type; POS RetailSaleTransactions keyed Txn × line; S/4 aggregate postings keyed Aggregation#. Joins: MATNR × WERKS × LGORT ↔ ISM node via the node map (801 inventory / 800 selling location is why the map is a table, not a rule); Aggregation# ↔ POS header ↔ lines. Revealed: the books legitimately disagree at every instant because of cadence, so the disagreement must be explained by an identity, not argued.

2 · Solution design. Options: (A) make S/4 the promising truth — rejected, it cannot see a 09:14 web order or a 15:30 parcel before the aggregate posts; (B) let each consumer compute its own available from the feeds — rejected, that is the two-dialect problem again; (C) one engine beside S/4 publishes AFS, consumers never compute, and S/4 keeps the book — chosen. Inside C: symmetric vs asymmetric basis — asymmetric chosen (surplus never promised).

3 · Math & data logic. OOB = S4_Avail − WMS_OnHand; Basis = min(S4_Avail, WMS_OnHand); AFS = Basis − PickRes − EcomPick − EcomPack − SNB; FOH = Avail + MerchRes + LostFound; Drift = ISM.S4_Avail − MB52 = 0; identity ISM_S4_Avail = (AFS − P) + PickRes + EcomPick + EcomPack + SNB + max(OOB, 0). Worked below on one SKU through twelve events.

4 · Implementation. Five gated phases above; cutover: clear negatives → transfer AFS to Uncommitted → scan-and-reserve → zero-then-publish; rollback triggers per interface; hypercare exit at drift 0 on consecutive days. Risks: vocabulary drift, feed latency, override abuse.

5 · Probe questions. Below: is FOH before or after reserves; why isn't S/4 the truth; what breaks at the watermark; who owns the publish; and the trap drills.

FACET 5 — PROBE QUESTIONS (CHALLENGE Q&A TUNED TO THIS INTERVIEWER)

Infra — where is the single source of truth for "available," and why isn't it S/4?

Physical stock truth is S/4, full stop. Promisable truth is ISM's published AFS, because S/4 posts documents and settles store sales as a nightly aggregate while promising needs every click and scan. The two are reconciled, not merged: ISM's copy of Available must equal MB52 daily at tolerance zero, and Financial On-Hand must tie to MB5L at month-end.

Infra — is Financial On-Hand before or after reserves?

It includes them. FOH = Available + Merchandise Reserve + Lost-and-Found — it is Finance's physical number, so a held unit is still on hand. AFS is the number after reserves and after every committed bucket. Reserve sits outside Available by construction, so it is never subtracted from AFS twice. Shipped-Not-Billed is carried as its own column so Finance can see what has left the floor but not yet posted.

see Verify #1–2 on the SNB term

Infra — what is the join key between S/4 and ISM, and where does it drift?

MATNR × WERKS × LGORT maps one-to-one to an ISM node through the node map; the sold-not-posted bucket joins on Aggregation# back to POS lines. It drifts in two places: an unmapped movement type — a new BWART nobody told ISM about, quarantined, never guessed — and a late goods receipt that crosses the snapshot watermark, which is why the drift report attributes timing rows before anyone calls a Sev.

Infra — who owns the publish?

ISM's AFS engine is the only publisher — per SKU × node × channel, key MATNR × node × channel × version, event to republish p95 under 60 seconds. The OMS, dotcom and the stores read it and never compute. At cutover no SKU could be published from two locations at any instant: zero on the old publish, then 100% on the new.

Infra — why not just trust MARD?

On S/4 MARD is trustworthy — it is a view over MATDOC, not a drifting aggregate — but it answers "what is booked," not "what may be promised." It cannot see a web order placed at 09:14 or a parcel that left at 15:30 before the aggregate posts. So I used it as the anchor of the identity and built the reports to prove every other term against it.

BUSINESS IMPACT MODEL — KPI DRIVERS, BASELINE → AFTER

DRIVER	BASELINE	AFTER	$ / EFFECT	BASIS
Published "available" values per SKU	2 books, per-org dialects	1 AFS per SKU × node × channel	—	record
Oversell incidents (customer-facing)	recurring (no count)	0 through both go-lives	≈$0.9M/yr exposure (30M × 0.10% × $30)	record / modeled
MCS support	$1M/yr	retired	$1.0M/yr	user anchor
Reconciliation	argument; ≈4 FTE by hand	daily identity, tolerance 0; ≈1 FTE reading it	≈$0.33M/yr	modeled
Change premium (two books to keep in step)	40 changes × 60 h × $125	one engine	≈$0.3M/yr	modeled
Total	—	—	≈$2.5M/yr = $1.0M anchor + ≈$1.53M modeled	split always

THE CALCULATION WALK — ONE SKU, ONE NODE, ONE DAY: FORMULA → SUBSTITUTION → VALUE AT EVERY STEP NEW

Setup (illustrative, canon family). SKU 12345 at the Utah DC, ISM node 801 (dotcom inventory location; selling location 800), the day after the 06:00 MB52 snapshot. Opening: S/4 Available 1,000; WMS on-hand 980 — the floor count with shipped-not-posted netted back per R6, so 980 = 940 units physically pickable + 40 units shipped-not-posted; Picking Reserve 200 (open STOs to stores); Ecom Pick 120; Ecom Pack 60; Shipped-Not-Billed 40 (omni pending-sale lines that settle on the nightly aggregate); Merchandise Reserve 150 and Lost/Found 0 outside Available. FRAME channel reserve is 0 in this walk, so the dotcom channel's published AFS equals the node AFS (the per-channel priority walk is S2 / Packet 3 U1). Promisable in-transit P = 0 at this node. Every row below is asserted by the recompute script.

Table W1 — the day's event ledger: which physical event moves which bucket, and what AFS does.

#	TIME · PHYSICAL EVENT → SYSTEM EVENT	S4_AVAIL	WMS FLOOR (NETTED)	OOB	BASIS	PICKRES / ECOMPICK / ECOMPACK / SNB	Σ BUCKETS	AFS
E0	06:00 MB52 snapshot; ISM copy refreshed (R1)	1,000	980	+20	min(1,000, 980) = 980	200 / 120 / 60 / 40	420	980 − 420 = 560
E1	07:30 trailer unloaded; PO goods receipt 101 for 240 EA posts in S/4; WMS holds them in receiving-staging status (not pickable)	1,000 + 240 = 1,240	980 (staging excluded)	1,240 − 980 = +260	min(1,240, 980) = 980	200 / 120 / 60 / 40	420	980 − 420 = 560 (dock units not promisable)
E2	09:10 putaway complete; WMS status → pickable; feed lands inside 15 min	1,240	980 + 240 = 1,220	1,240 − 1,220 = +20	1,220	200 / 120 / 60 / 40	420	1,220 − 420 = 800 (republished < 60 s)
E3	09:14 dotcom order committed, 30 EA (OMS commit event)	1,240	1,220	+20	1,220	200 / 120 + 30 = 150 / 60 / 40	450	1,220 − 450 = 770
E4	10:02 STO created for store replenishment, 100 EA (retail channel)	1,240	1,220	+20	1,220	200 + 100 = 300 / 150 / 60 / 40	550	1,220 − 550 = 670
E5	11:20 RF pick confirm and pack confirm, 50 EA of the open ecom lines	1,240	1,220	+20	1,220	300 / 150 − 50 = 100 / 60 + 50 = 110 / 40	550	670 — unchanged: bucket-to-bucket
E6	13:05 WMS ship confirm, 90 EA leave the dock (parcel) → SNB += 90	1,240	1,090 physical + 130 SNB = 1,220	+20	1,220	300 / 100 / 110 − 90 = 20 / 40 + 90 = 130	550	670 — unchanged: already promised
E7	13:20 S/4 delivery goods issue 601 posts for the 90 (intraday); matched to the ship confirm → SNB −= 90	1,240 − 90 = 1,150	1,090 + 40 = 1,130	1,150 − 1,130 = +20	1,130	300 / 100 / 20 / 130 − 90 = 40	460	1,130 − 460 = 670 — unchanged
E8	14:00 STO goods issue 641, 100 EA on the truck to the store (in-transit shows on MB5T)	1,150 − 100 = 1,050	990 + 40 = 1,030	1,050 − 1,030 = +20	1,030	300 − 100 = 200 / 100 / 20 / 40	360	1,030 − 360 = 670 — unchanged
E9	16:10 rack leak: WMS moves 700 EA to damaged/hold status; S/4 transfer posting awaits IC approval	1,050	290 + 40 = 330	1,050 − 330 = +720	min(1,050, 330) = 330	200 / 100 / 20 / 40	360	330 − 360 = −30 → publish 0; Negative AFS row (R7)
E10	16:40 IC approves; S/4 posts unrestricted → blocked 700 EA (→ MerchRes 150 + 700 = 850)	1,050 − 700 = 350	330	350 − 330 = +20	330	200 / 100 / 20 / 40	360	−30 — the over-commit is real: 30 promised EA cannot ship from 801
E11	16:55 AFS Correction (role + audit row, cause class "latency/physical"): OMS re-sources 30 EA of open ecom lines to node 901	350	330	+20	330	200 / 100 − 30 = 70 / 20 / 40	330	330 − 330 = 0 — negative clean before T+1
E12	17:00 watermark: T+1 reconciliation (R2) — see Table W4	350 = MB52 350	330	+20	330	200 / 70 / 20 / 40	330	0; Drift = 350 − 350 = 0

Reading the ledger: a receipt moves S/4 first and the floor second (E1 → E2), so AFS waits for putaway — time-to-available is the dock-to-stock window. Commit and STO creation move AFS (E3, E4); pick, pack, ship and goods issue do not (E5–E8) — they move units between buckets or out of both books at once. A physical loss moves AFS instantly through the floor (E9), and the book catches up on a document (E10). The published number is never negative; the negative is a row with an owner (E9–E11).

Table W2 — the four formulas, symbolic → substituted → computed, at three instants.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	OOB at E0	OOB = S4_Avail − WMS_OnHand = 1,000 − 980	record formula	+20 (book above floor)
2	Basis at E0	Basis = min(S4_Avail, WMS_OnHand) = min(1,000, 980)	record formula	980
3	AFS at E0	AFS = Basis − PickRes − EcomPick − EcomPack − SNB = 980 − 200 − 120 − 60 − 40	record formula; canon walk	560
4	Flip the floor (asymmetry)	WMS 1,020 → OOB = 1,000 − 1,020 = −20 → Basis = min(1,000, 1,020) = 1,000 → AFS = 1,000 − 420	canon walk	580, not 600 — surplus unpromised
5	AFS at E2 (after putaway)	Basis = min(1,240, 1,220) = 1,220; AFS = 1,220 − (200 + 120 + 60 + 40)	illustrative	800

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
6	Real-time decrement E2 → E4	AFS(t) = AFS(t_0) − Σ Δ_e = 800 − 30 (commit) − 100 (STO)	record contract	670
7	Bucket-to-bucket conservation E5–E8	Σ buckets − (Basis change) : 550 → 550 → 460 (−90 with Basis −90) → 360 (−100 with Basis −100); AFS 670 each time	illustrative	670 unchanged
8	FOH at E0 (DC)	FOH = Avail + MerchRes + LostFound = 1,000 + 150 + 0	record formula (S1); SNB term see Verify #2	1,150
9	FOH at E12	350 + 850 + 0	record formula	1,200
10	Physical cross-check at E12	present = 290 pickable + 700 damaged + 150 reserve = 1,140; + 40 shipped-not-posted = 1,180; FOH − 1,180 = 20 = the open OOB row	illustrative; OOB row to IC with cause code (R6)	20 = OOB

Table W3 — what goes wrong, one variant per control, with the number.

CONTROL	VARIANT (WHAT GOES WRONG)	FORMULA → SUBSTITUTION	CAUGHT BY · OWNER	EFFECT ON AFS
R9 idempotency	The 13:05 ship confirm for 90 EA is replayed at 13:07	same key OMS × OrderLine × line × ship → no-op; AFS stays 670. If applied: EcomPack 20 − 90 = −70 (rejected: bucket < 0) / SNB 130 + 90 = 220 → AFS 1,220 − 640 = 580	R9 replay audit · ISM app team	0 (would have been −90, safe direction)
WMS feed SLA	At E2 the floor feed ages past 15 min	publish suppressed for node 801; last-good AFS 560 held and flagged; the 240 dock units stay unpromised; undersell bound = 240 × $4.75 = $1,140 if all 240 would have sold in the window	feed-latency monitor · WMS team	held at 560 (undersell, never oversell)
R2 Test A (timing)	Extract pulled 17:05; a 101 for 24 EA posted 17:03	S/4 374 − ISM 350 = +24 → MATDOC CPUTM 17:03 > watermark 17:00 → timing; MB5B re-cut at 17:00 → 350 − 350 = 0	R2 drift · ISM engineers fix the extract (cut by posting time)	0 after re-cut; no Sev
R6 cutoff	WMS snapshot at 17:00, S/4 snapshot at 13:00	phantom OOB = day's goods issues = 90 + 100 = 190; Basis understated by 190 → AFS 0 − 190 → published 0 and a false negative row	R6 same-cutoff rule · Inventory Control	−190 phantom (safe direction, but a false Sev)
R7 Negative AFS	E9: 700 EA to damaged while 360 committed	AFS = 330 − 360 = −30 → publish 0, write row; exposure 30 × $30 = $900	R7 · Inventory Control + Internal Audit + Finance; fix via AFS Correction	−30 → 0 at E11
R4 tie-out	OMS shows 31 open ecom lines for 801 after E11, ISM EcomPick 70 for 70 units of 31 lines; STO side Σ open STO = 200	Σ open STO 200 − PickRes 200 = 0 ✓; Σ open orders 70 − EcomPick 70 = 0 ✓ — a break here is a lost or duplicated event, never a units problem	R4 · ISM engineers first	0
R8 unmatched	Nightly aggregate for the 40 omni lines arrives as 38 EA	Σq_i 40 ≠ q_P 38 → park; SNB stays 40; S4_Avail drops 38 → AFS under-stated by 2 until the lines land; >24 h flag, >48 h Sev	R8 unmatched-aging · Inventory Accounting	−2 (safe direction)
R10 publish switch	Cutover: SKU 12345 found published from both 800 and 900	rule: published locations per SKU = 1 at every instant; zero on old → 100% on new; Σ AFS conserved across the switch	R10 balance sheet · war room	0 double-publish allowed

Table W4 — T+1 reconciliation: the two tests on the worked row (watermark 17:00).

STEP	TEST	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Test A — external: book vs copy	MB52_Avail − ISM.S4_Avail = 350 − 350	record; tolerance 0; ≠ 0 is a Sev until classified	0 ✓
2	Test B — internal identity	ISM_S4_Avail = (AFS − P) + PickRes + EcomPick + EcomPack + SNB + max(OOB, 0) = (0 − 0) + 200 + 70 + 20 + 40 + 20	record identity	350 ✓
3	Test B at E0 (sanity)	(560 − 0) + 200 + 120 + 60 + 40 + 20	canon family	1,000 ✓
4	Why both tests	a duplicate 601 consumed twice: ISM 340 vs MB52 350 → Test A −10, Test B still ✓ (engine did correct arithmetic on a wrong input)	record lesson (GFiber R2 row 3)	Test A catches it
5	Negative AFS clean at T+1	rows with AFS < 0 at 17:00 for node 801 = 0	record exit bar	0 ✓
6	Month-end	Σ_n FOH_n × MBEW-VERPR ties to MB5L; tolerance 0 units; a value gap is a WAC question (S/4 owns)	record mechanism; days-to-tie not in record	ties

THE MATH — FOUR-TABLE DERIVATION (DOLLARS; FORMULA → SUBSTITUTION → RESULT) NEW

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Published "available" values per SKU	`MCS + S/4 = 2, each read by different orgs`	record	2
2	Oversell exposure (baseline)	`30,000,000 orders × 0.10% × $30`	illustrative base; benchmark rate; $30 all-in	$900,000/yr
3	Reconciliation labor	`≈4 FTE × $110,000`	benchmark	$440,000/yr
4	MCS support	`$1,000,000`	user anchor	$1.0M/yr
5	Change premium	`40 changes × 60 h × $125`	benchmark	$300,000/yr

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	One basis	`Basis = min(1,000, 980)`	record	980
2	One AFS	`980 − (200 + 120 + 60 + 40)`	record	560
3	One publisher	`published AFS values per SKU × node × channel = 1; consumers compute = 0`	record	1
4	One identity, daily	`Drift = 350 − 350 = 0; tolerance 0`	record	0
5	Reconciliation after	`≈1 FTE × $110,000`	benchmark	$110,000/yr

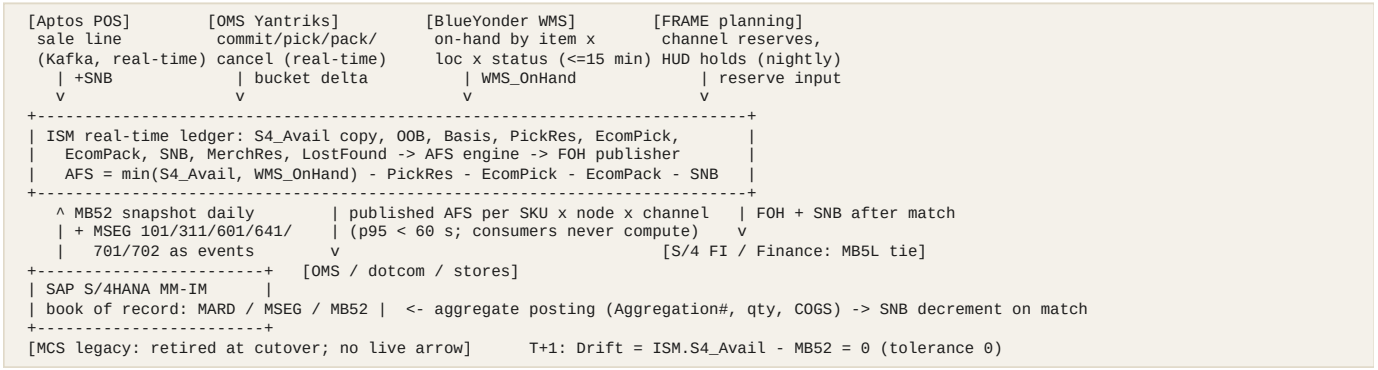

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Books publishing "available"	2	1 (S/4 keeps the physical book; ISM publishes)	record
2	Customer-facing oversell incidents	recurring	0 through both go-lives	record
3	Drift ISM vs MB52	unmeasured	0, tolerance 0, daily	record design
4	Negative AFS at cutover	present (MCS: e.g., 400 of 1,800 SKUs in one department — issues-log row 716, UDC log)	clean at T+1	record-from-docs / record
5	Reconciliation FTE	≈4	≈1	benchmark

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Oversell avoided	`30,000,000 × 0.001 × $30 = $900,000`	modeled	$0.90M
2	Reconciliation released	`(4 − 1) × $110,000 = $330,000`	modeled	$0.33M
3	Change premium	`40 × 60 × $125 = $300,000`	modeled	$0.30M
4	Modeled subtotal	`900,000 + 330,000 + 300,000 = $1,530,000`	modeled	≈$1.5M
5	MCS support retired	`$1,000,000`	user anchor	$1.0M
6	Headline	`1,000,000 + 1,530,000 = $2,530,000`	anchor + modeled — always split	≈$2.5M/yr
7	Exposure of the worked negative	`30 × $30 = $900`	illustrative	$900

SOLUTION FLOW — THE SYSTEM & DATA MAP

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Oversell rate (30M orders × $30)	0.05% → $450K	0.10% → $900K	0.25% → $2.25M

INPUT	LOW	BASE	HIGH
Reconciliation FTE released × $110K	2 → $220K	3 → $330K	4 → $440K
Change premium (changes × 60 h × $125)	20 → $150K	40 → $300K	60 → $450K
Modeled total (excl. $1M anchor)	$820K	$1.53M	$3.14M
Dock-to-stock window on the 240 EA (E1 → E2)	40 min	100 min	4 h → publish held longer; undersell only

SPOKEN STATEMENT

"Two books each said 'available' and meant different things, so I wrote the one definition and got it signed. S/4 owns the physical book — unrestricted stock per SKU, plant and storage location. ISM takes the lower of that book and the warehouse floor as the basis, subtracts Picking Reserve, Ecom Pick, Ecom Pack and Shipped-Not-Billed, and publishes one available-for-sale per SKU, node and channel; the order system reads it and never computes. On the worked SKU that is the lower of 1,000 and 980, less 420 committed, 560. A receipt does not move it until putaway; a commit moves it in under a minute; a pick, a pack or a ship moves units between buckets and leaves it alone; a loss on the floor moves it instantly and the book catches up on a document. Every morning ISM's copy of the book must equal MB52 at tolerance zero — a difference is a Sev, not a planning variance — and every booked unit must sit in exactly one bucket. The record is oversell from recurring to zero through both go-lives and negatives clean at T+1; the dollar view is about $2.5M a year — $1M of MCS support retired, and roughly $1.5M modeled."

IF CHALLENGED

"Your oversell number is the biggest modeled piece — how do you know it was a tenth of a percent?"

I don't know it to the decimal. The record says the incidents were recurring and went to zero; the rate is a benchmark I set deliberately low. The first thing I'd measure is the OMS cancel-reason code "item unavailable after order" for the twelve months before January.

"The ship confirm and the goods issue both touch SNB — isn't that double counting?"

No — they are the two halves of one movement. The ship confirm adds 90 to SNB and removes 90 from the floor; the floor is netted by SNB for the OOB comparison, so Basis is unchanged and so is AFS. When the 601 posts, S/4 Available drops 90 and the matched SNB drops 90 — Basis falls 90 and the buckets fall 90 together. AFS is 670 before, during and after. The walk shows it at E6 and E7.

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Walk me through how availability was actually calculated.	Dive Deep	Table W1 from the top: E0 → E12, name the bucket at each step.	Never quote the unit counts as program data.
What was the simplest thing you did on a complex program?	Invent and Simplify	One identity, one publisher, consumers never compute.	Do not claim I built the engine.
Tell me about a time you said no to a stakeholder.	Have Backbone	The surplus is never promised: 580, not 600.	Do not say Merchandising was wrong — they had a real visibility need (U3).
How did you get three orgs to agree?	Earn Trust	A table, not a meeting: term, definition, system of record, grain, owner — signed.	Say "three orgs" only if confident; names are user anchor.

BEHAVIORAL PACK — FOUR SEPARATE 90-SECOND STAR ANSWERS, EACH FROM A DIFFERENT MOMENT OF THE STORY

NEW

DIVE DEEP · AIQB Q1 **Q1. "Tell me about a time when you were trying to understand a complex problem on your team and you had to dig into the details to figure it out. Who did you talk with or where did you have to look to find the most valuable information?"**

The complex problem was that two inventory books disagreed every day and nobody could say which was wrong. I stopped asking people what "available" meant and went to the documents: MARD unrestricted by SKU, plant and storage location on the S/4 side; the WMS on-hand by status; the OMS order-line events; the POS transaction lines; and the nightly aggregate posting that is the only way a store sale reaches S/4. Then I walked one SKU through one day — a receipt at 07:30 that S/4 sees before the floor does, a putaway at 09:10 that makes it promisable, a web commit at 09:14, a store transfer at 10:02, a pick and pack that move units between buckets, a ship confirm and a goods issue that move them out of both books together. That walk showed the books legitimately disagree at every instant because of cadence, so the fix was not a better spreadsheet but an identity: every booked unit sits in exactly one bucket, asserted daily at tolerance zero. The most valuable information came from Inventory Control's morning reconciliation and the ISM transition log — the people and the table that saw every break.

Number to land: Basis min(1,000, 980) = 980; AFS 980 − 420 = 560; drift 0 · **Pivot to NACF:** At an FC the same walk is receive scan → stow → available: I would ask which system is the book, which is the floor, and what the identity between them is. · **Do NOT say:** that the unit counts are program data; that I built the extracts.

INVENT AND SIMPLIFY · AIQB Q1 **Q2. "Give me an example of a complex problem you solved with a simple solution. What made the problem complex? How do you know your solution addressed the problem?"**

The complexity was five feeds at five cadences — S/4 documents, a 15-minute warehouse feed, real-time order events, real-time store sales, and a nightly aggregate posting — and about a dozen impacted systems each tempted to compute its own available. The simple solution was one identity and one publisher. Basis is the lower of the book and the floor; available-for-sale is Basis minus four committed buckets; ISM publishes it per SKU, node and channel; everyone else reads it and never computes. Merchandise reserve and lost-and-found sit outside the book by construction so no double subtraction is possible. I know it addressed the problem because the identity is checkable: ISM's copy of the book equals MB52 every morning at tolerance zero, and the book equals AFS plus the buckets plus the positive out-of-balance. The record is oversell from recurring to zero and negatives clean at T+1 at cutover.

Number to land: 1 published AFS per SKU × node × channel; identity 350 = 0 + 200 + 70 + 20 + 40 + 20 · **Pivot to NACF:** At NACF I would want one published available per ASIN × FC that placement and transfer read and never recompute. · **Do NOT say:** "simple" meant "easy" — it took a signed FSD and a 343-task cutover.

HAVE BACKBONE; DISAGREE AND COMMIT · AIQB Q2 **Q3. "Describe a time when you took an unpopular stance in a meeting with peers and your leader. What was it? Why did you feel strongly about it?"**

The stance was that a surplus on the warehouse floor is never promised until S/4 books it — and the room wanted the units. If the floor shows 1,020 and the book shows 1,000, the symmetric rule says promise 1,020 less commitments; I set Basis to the lower of the two, so AFS is 580, not 600, and twenty sellable units sit unpromised. The argument against me was lost sales. My argument was asymmetry: an oversell is a customer we have already told yes and cannot ship — about thirty dollars on benchmark inputs; an undersell is a planning variance Inventory Control chases through the out-of-balance report. With no measured phantom rate at design time I set the probability that a surplus is phantom to one and let the Negative AFS and correction screens chase the undersell. Leadership accepted the undersell. I committed to the cost — more investigations — and the record is zero oversell through both go-lives.

Number to land: 580, not 600; OOB −20 never promised · **Pivot to NACF:** Same stance on dock-received versus system-available: I would not promise a unit that is scanned but not stowed. · **Do NOT say:** that the lost sales were zero; that Merchandising was wrong to ask.

EARN TRUST · AIQB Q1 **Q4. "Tell me about a time when you had to communicate a change in direction that you anticipated people would have concerns with. What did you do to understand the concerns and mitigate them?"**

The change in direction was that S/4 would keep the physical book but would no longer be where anyone read "available" — ISM would publish it. Finance heard "you are taking our number away"; the DC heard "a system will tell us what we can pick"; dotcom heard "you will under-promise." I understood the concerns by writing them as rows: what each org needed to read, at what grain, from which document. Finance needed Financial On-Hand to tie to MB5L at month-end — it does, from ISM, at tolerance zero in units, with cost staying S/4-owned. The DC needed the floor to win when it was lower — it does, by the lower-of-two rule. Dotcom needed republish within a minute — the contract is p95 under sixty seconds. The mitigation was the signed table: term, definition, system of record, grain, owner. Three orgs signed it in the FSD. What changed along the way: merchandise reserve got its own visible column because Merchandising's real need was visibility, not promisability.

Number to land: three orgs signed; FOH ties to MB5L at tolerance 0; p95 < 60 s · **Pivot to NACF:** At NACF a definition change — what counts as "received" or "available" — gets a signed table before it gets a system. · **Do NOT say:** the signing orgs' names unless confident (user anchor); the FSD day if unsure — "first week of June."

SAME STORY, THREE ANGLES — DATA · CONFLICT/INFLUENCE/BACKBONE · FAILURE-LEARNING NEW

DATA ANGLE · DIVE DEEP	CONFLICT / INFLUENCE ANGLE · HAVE BACKBONE	FAILURE / LEARNING ANGLE · ARE RIGHT, A LOT
"One SKU, twelve events, four formulas — and the identity held at 17:00." **Headline metric:** Drift = 350 − 350 = 0; Test B = 350 Grain SKU × node × channel × as-of; five feeds, five cadences; the walk shows which events move AFS (commit, STO, floor loss, putaway) and which do not (pick, pack, ship, goods issue). Honest limit: the unit counts are illustrative; the formulas and tolerances are record.	*"The surplus is never promised — 580, not 600."* **Headline metric:** OOB −20 unpromised; oversell → 0 The room wanted the units; I priced the asymmetry ($30 oversell vs $4.75 undersell, benchmark) and set the phantom probability to one at design time. Leadership accepted visible undersell. Influence: a priced rule in the FSD, not a meeting.	*"My first in-transit rule starved a channel — and the Negative AFS screen could not see it."* **Headline metric:** P = 0 by default; undersell invisible to a one-sided detector The master's S4: I first refused to promise against in-transit, then the lane study reversed me (σ ≈ 0.3 day → a ~0.49-day window). Do differently: a watch on unusual undersell beside the Negative AFS report — the detector is blind in that direction by design.

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS, WITH NUMERIC ANSWERS NEW

Definitional — is Financial On-Hand before or after reserves? And why isn't Shipped-Not-Billed in it?

FOH includes reserves: Available + Merchandise Reserve + Lost-and-Found = 1,000 + 150 + 0 = 1,150 at the open; a held unit is still on hand. AFS is after reserves and after every committed bucket: 560. SNB is units that have physically left but S/4 still books — they are inside Available until the posting, so FOH carries them already; SNB is shown as its own column so Finance sees what tonight's posting will remove.

canon carries two FOH phrasings — Verify #2

Say: *"FOH is Finance's physical book including reserve; AFS is the promise after reserve and commitments; SNB is the reconciling column between them."*

Definitional — what if S/4 and ISM disagree at T+1?

Test A breaks and it is a Sev until classified. Pull MATDOC lines for that SKU × SLoc with posting time after the watermark — timing, re-cut with MB5B (the +24 row); pull the ISM transition log for a duplicate MBLNR × ZEILE — consumer defect, drop by key and replay (the −10 row); anything left is true drift to Inventory Control with a cause code. Never adjust the book to match the copy.

Say: *"A T+1 difference is a Sev until it has a cause class — timing, duplicate, or true drift — and the book is never edited to make the copy right."*

Definitional — who owns the publish, and what stops two values for one SKU?

ISM's AFS engine is the only publisher, keyed SKU × node × channel × version; the OMS and stores read and never compute; the assortment flag gates dotcom publish. At cutover the rule was published locations per SKU = 1 at every instant — zero on 800 and 900's old publish, then 100% on the new — and Σ AFS was conserved across the switch; rollback triggers (sync < 99% for 4 h, p95 > 2× for 1 h) were armed twice and never fired.

Say: *"One publisher, one key, consumers never compute — and at cutover no SKU was ever published from two places at once."*

20-SECOND VERSION + NACF BRIDGE NEW

20-second version. At Sephora two books each published "available"; I wrote the one signed definition — Basis is the lower of S/4 book and WMS floor, AFS is Basis minus Picking Reserve, Ecom Pick, Ecom Pack and Shipped-Not-Billed — one engine publishes it per SKU, node and channel, consumers never compute, and ISM's copy equals MB52 daily at tolerance zero. Oversell went from recurring to zero through both go-lives; about $2.5M a year, $1M retired support plus roughly $1.5M modeled.

NACF bridge. NACF's equivalent is time-to-available and the identity behind it: receive scan → stow → available, with dock-received units not promisable until stowed (the E1 → E2 window is the dwell side of CAP-D), one published available per ASIN × FC that placement and transfer read, and a zero-tolerance reconciliation between the WMS book and the physical count. I would ask first which system is the book, which is the floor, and what the daily identity between them is.

Safe-say box. "S/4 owns the physical book; ISM publishes the promise; the two are reconciled daily at tolerance zero, never merged." · "Every unit count in my walk is illustrative; the formulas, the tolerance and the result — zero oversell through both go-lives — are the record."

S1-R-infra — Physical truth vs system truth: the infrastructure view of the same program — scan to WMS to S/4 posting, which physical event moves which bucket, what AFS does when a feed or a device is late, and the cutover night from the infrastructure seat NEW

LPs this story serves here: Insist on the Highest Standards (primary — tolerance zero; publish suppressed rather than computed on a stale floor) · Are Right, A Lot (the RF-device script miss, owned) · Bias for Action (stale feed on the cutover wall) · Deliver Results (343 tasks, triggers armed twice, never fired)
Process family: Deliver — physical-to-system latency design, node constraints, cutover runbook and rollback from the infrastructure seat

Honesty label. Record design (FSD / GFiber v8 ISM chapter): WMS on-hand feed ≤ 15 min, late ⇛ publish suppressed for that node, last-good AFS held and flagged; event → republish p95 < 60 s; S/4 movement lines as real-time events; POS lines real-time; S/4 aggregate posting nightly / intraday batch; unmatched > 24 h flag, > 48 h Sev. Record (Apple C2 p24 / resume / SAP Narrative p4): cutover runbook 343 tasks / 48,885 task-minutes ≈ 815 hours; rollback triggers sync < 99% for 4 consecutive hours or order-flow p95 > 2× budget for 1 hour, consumers revert to the prior publish; armed for both go-lives, never fired. Record (Apple G2 p44–45, the S18 RP → JDA WMS program at the same DC family): device test scheduled with engineering days before training; the upgrade script failed on refreshed RF hardware; "hundreds" of devices; 3–4-day estimate; training slipped 1.5 weeks; go-live date held; program landed ~3% under the ~$1.8M budget; mocks 7.0% → 1.8% → 0.3% vs 0.5% tolerance; the what-if rule became the UDC RF-device proof-of-concept before cutover week (Apple G2 p45). Record (Apple D1 p29): 72-hour in-transit freeze; RP read-only 30 days. Illustrative: the 12 EA/hour sell rate, 10 doors × 16 h, 120 UPH, the cutover-night clock times. I owned the latency budgets, the suppression rule, the runbook and the triggers; the WMS, ISM and S/4 engineers built the feeds; DC Ops ran the floor and the devices.

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH

Insist on the Highest Standards. When the floor feed ages past fifteen minutes the engine holds the last good number and flags the node rather than compute on a lie; drift tolerance is zero.

Are Right, A Lot. I scored a "three-day" device task by effort, not impact; the script failed on new hardware; training slipped a week and a half, the date held, and the what-if rule is permanent.

Bias for Action. On the cutover wall a stale node feed is a re-read, not a re-promise — the rule was decided before anyone was tired.

Deliver Results. 343 tasks, about 815 task-hours, one irreversible instant; rollback armed twice and never fired; zero customer-facing incidents.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. The availability program lived or died on physical truth reaching system truth in time: an RF scan on the Utah DC floor had to become a WMS status, a WMS status had to reach ISM inside fifteen minutes, an S/4 document had to post as a real-time event, and the published number had to move in under a minute — across hundreds of devices, a dock, a labor plan and a cutover that could not break a peak. **Task.** Own the latency budgets, the rule for what the engine does when physical truth is late, the device and dock dependencies in front of the exit criteria, and the cutover runbook and rollback triggers. **Action.** I wrote the budgets as numbers: floor feed fifteen minutes or publish is suppressed for that node with the last good value held and flagged; event to republish p95 under sixty seconds; store sales real-time, settlement nightly with a twenty-four-hour flag and forty-eight-hour Sev. I mapped every physical event to exactly one bucket transition — receipt, putaway, pick, pack, ship, goods issue, adjustment — so the floor could never move a unit the system did not see. On the earlier WMS migration I had missed a device dependency — a three-day script that failed on new hardware and slipped training a week and a half — so device readiness went into the entrance criteria and an RF-device proof-of-concept ran before cutover week. The cutover was 343 tasks, about 815 hours, inside a transfer freeze, with one irreversible instant — zero-then-publish — and rollback triggers per interface: sync under 99% for four hours or p95 over twice budget for an hour. **Result.** Primary metric: two go-lives, zero customer-facing incidents, rollback armed twice and never fired; a node whose feed went stale under-sold for minutes and never over-sold.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — Four physical cadences met one published number. A trailer on the dock was in S/4 before it was on the floor; a parcel was off the floor before S/4 knew; a store sale reached S/4 only as a nightly aggregate; a rack leak was on the floor minutes before any document. Hundreds of RF devices, printers and workstations had to run the new code; the dock, labor and cube constraints decided how long the dock-to-stock window was; and a cutover had to move the publish without a SKU ever being promisable from two places.

T — Decide, in numbers, how late physical truth may be before the system stops promising; map every physical event to one bucket; put device and dock readiness in front of the exit criteria; and run the cutover night as a runbook with stop conditions.

Baselines on the table: WMS feed ≤ 15 min · republish p95 < 60 s · aggregate nightly, > 24 h flag, > 48 h Sev · "hundreds" of devices (record) · 343 tasks ≈ 815 h · triggers 99% × 4 h / 2× × 1 h · 72-hour in-transit freeze (S18 lesson) · zero customer-facing incidents allowed.

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery (3/29 → 4/30)** — walked the floor with DC Ops: every scan point (receive, putaway, pick, pack, ship, cycle count) and what it posts where; feed cadences and owners; the device fleet and its code level. *Exit bar:* every physical event has one target bucket and one owner; every feed has a cadence and a late rule.

- **Plan & Design (5/15 → 8/14)** — latency budgets written as numbers; the suppression rule (stale floor ⇒ hold last-good, flag the node); the same-cutoff rule for OOB; device readiness and dock readiness as entrance criteria (the G2 what-if rule). *Exit bar:* budgets in the FSD; what-if and fallback per cross-functional dependency.
- **Build & Test (Aug → Jan/Apr)** — the RF-device proof-of-concept before cutover week (record); three mock cutovers against the 0.5% tolerance (7.0% → 1.8% → 0.3%, the S18 arc applied); the replay test; E2E days. *Exit bar:* devices proven, not promised; mock 3 inside tolerance.
- **Cutover & Go-Live (January; May 1 → Jul 1)** — transfer freeze; MCS closing extract · S/4 opening MB52 · ISM seed balanced per bucket (R10); clear negatives; zero-then-publish; OMS re-pointed; triggers armed per interface. *Exit bar:* Σ per bucket equal across the three columns; no SKU published twice; first drift at T+1 = 0.
- **Hypercare / Close (Jun → Jul)** — feed-latency and stale-node flags read on the wall every morning; triggers disarmed only at exit. *Exit bar:* < 2 blockers/day sustained; drift 0 on consecutive days; stale-node flags at zero for a week.

Influence and ownership. Mine: the budgets, the suppression rule, the event-to-bucket map, the entrance criteria, the runbook and the triggers. WMS, ISM and S/4 engineers built the feeds and the jobs; DC Ops owned the floor, the devices and the dock; the war room read the wall.

> **Designed the process; others own it now.** The feed monitors and stale-node flags are Inventory Control's morning read; device readiness is a standing line in every DC runbook. **Trade-off put to leadership:** suppress publish on a stale node (lost sales for minutes) against promising on a floor count that may be wrong; leadership accepted suppression.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY

- **$** — the program protected the S1 headline (about $2.5M a year, split $1M anchor + ≈$1.5M modeled); the S18 migration landed ~3% under ~$1.8M (≈$54K, record / derived). No infrastructure dollar is claimed as savings.
- **#** — 343 tasks; 48,885 task-minutes; one irreversible instant; 2 rollback triggers per interface, armed twice, never fired; "hundreds" of devices proven before training.
- **%** — mocks 7.0% → 1.8% → 0.3% against 0.5% (record, S18); feed completeness design ≥ 99.9%; sync trigger 99%.
- **Time** — floor feed ≤ 15 min; republish p95 < 60 s; dock-to-stock on the worked receipt 100 min (illustrative); training +1.5 weeks with the date held (record).
- **Customer** — zero customer-facing incidents through both go-lives (record).
- **Quality** — a stale node under-sells and never over-sells; every physical event lands in exactly one bucket (record design).

L6 LEVEL EVIDENCE — every line is this story's record or labeled model, no new canon numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	"How late is too late" had no number; I wrote 15 minutes, 60 seconds, 24 hours and 48 hours into the FSD.
Scope & influence	WMS, ISM and S/4 engineering, DC Ops, the device team and Finance — none reported to me.
Execution trade-off + mechanism others own	Suppression over promising on a stale floor; the mechanism others own: the stale-node flag and the feed monitor.
Impact	Two go-lives, zero customer-facing incidents, rollback never fired.
Process improvement	Device readiness moved from a promise to an entrance criterion; the what-if line per dependency is permanent.
Complexity & consensus	Four physical cadences, one published number, a cutover inside a freeze.
Root cause at scale	The device miss root-caused to the risk model (effort vs impact), not to the script.

PROBING — FIVE FACETS, THEN THE HARDEST FOLLOW-UPS NEW

THE FIVE FACETS — WHERE EACH ONE LIVES IN THIS STORY

1 · Data analysis. Grain: event × node × minute. Data: WMS feed as-of timestamps vs ISM receive time (latency distribution per node); ISM publish log (event time → publish time, p95); MATDOC posting time vs watermark; stale-node flags per day. Cuts: by node, by hour, by event type. Revealed: receipts are the slowest physical-to-promisable path (dock-to-stock), goods issues the fastest (document and floor move together); a stale feed hurts only on the floor side — commits keep flowing.

2 · Solution design. Options for a stale floor: (A) keep computing on the last floor count — rejected, promises against a floor that may have lost units; (B) fall back to S/4 book alone — rejected, book is above floor by whatever shipped; (C) hold last-good AFS, flag the node, keep applying commit decrements — chosen: under-sells, never over-sells. Device readiness: promised (rejected after G2) vs proven in an entrance criterion (chosen).

3 · Math & data logic. Exposure = sell rate × stale window; time-to-available = t_putaway − t_101; dock utilization = scheduled unloads ÷ (doors × hours × unload rate); hours = units ÷ UPH × gross-up; trigger exposure = events/hour × (1 − 0.99) × 4 h. Worked below.

4 · Implementation. Phases above; cutover-night runbook (Table 2); hypercare wall. Risks: device code level, feed latency, cutoff mismatch, a 101 across the watermark.

5 · Probe questions. Below: what dotcom sees if the feed dies for an hour; why rollback never fired; why trust the cutover after the device miss; what the dock has to do with AFS.

FACET 5 — PROBE QUESTIONS (CHALLENGE Q&A TUNED TO THIS INTERVIEWER)

Infra — the WMS feed dies for an hour. What does dotcom see?

The last good AFS for that node, flagged stale, still decremented by every commit that arrives — commits come from the OMS, not the WMS. What it cannot see is floor-side change: a putaway (so new stock under-sells until the feed returns) or a loss (so a commit could land on a unit that is gone). The exposure of the second is bounded by sell rate × window — on the worked SKU, 12 an hour × 1 hour = 12 units, and only if a loss happened in that hour. Suppression plus the Negative AFS report at T+1 is the control.

Infra — which physical event moves which bucket?

Receipt 101: S/4 Available up, floor unchanged until putaway — AFS waits. Putaway: floor up — AFS up. Commit: Ecom Pick up — AFS down. STO create: Picking Reserve up — AFS down. Pick/pack confirm: Ecom Pick to Ecom Pack — AFS unchanged. Ship confirm: Ecom Pack to SNB, floor down — AFS unchanged. Goods issue 601/641: S/4 Available down, SNB or Picking Reserve down — AFS unchanged. Cycle count 701/702: Lost/Found — outside AFS; a status change to damaged moves the floor — AFS down instantly.

Infra — what does the dock have to do with AFS?

Time-to-available. A unit is in S/4 at the 101 and promisable only at putaway, so dock-to-stock is a direct AFS lever: on the worked receipt 100 minutes for 240 units. Dock utilization above about 85% makes that window nonlinear, which is why the receive plan and the putaway labor plan are in the latency story, not just the IT story.

Infra — rollback never fired. Were the triggers too loose?

They were priced, not loose: sync under 99% for four consecutive hours — at an illustrative 1,000 events an hour that is more than 10 unapplied events an hour for four hours running — or publish p95 over twice the 60-second budget for a full hour. Both were observable on the wall in real time. They were armed for both go-lives. Not firing means the mocks did their job: 7.0% → 1.8% → 0.3% against 0.5% on the earlier migration, and the same discipline here.

BUSINESS IMPACT MODEL — KPI DRIVERS, BASELINE → AFTER

DRIVER	BASELINE	AFTER	$ / EFFECT	BASIS
Floor-to-system latency rule	none written	≤ 15 min or publish suppressed; last-good held and flagged	oversell exposure bounded by sell rate × window	record design
Publish latency	nightly / batch dialects	event → republish p95 < 60 s	stale-promise leak priced by the 60-s budget	record design
Device readiness	promised (3–4-day estimate)	proven in entrance criteria; PoC before cutover week	training +1.5 weeks once; never since	record
Cutover	—	343 tasks ≈ 815 h; triggers armed twice, never fired	≈$90K runbook effort at an illustrative $110/h	record / illustrative
Mock reconciliation	7.0%	0.3% vs 0.5% tolerance	—	record (S18)

THE MATH — FOUR-TABLE DERIVATION (FORMULA → SUBSTITUTION → RESULT) NEW

Table 1 — before: the latency problem in numbers (physical event → system truth).

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Time-to-available on the worked receipt	`t_putaway − t_101 = 09:10 − 07:30`	illustrative (S1-R E1 → E2)	100 min; 240 EA unpromisable
2	Floor-feed stale exposure	`sell rate × window = 12 EA/h × 15 min = 12 × 0.25`	illustrative sell rate; record 15-min budget	3 EA
3	Same exposure with a 1-hour outage and no suppression	`12 × 1.0`	illustrative	12 EA; $ = 12 × $30 = $360
4	Store-sale phantom window (no SNB)	`W = t_post − t_sale; a 10:02 sale posts at the nightly aggregate ≈ 14 h; exposure ≈ sales rate × W`	record formula (S3); illustrative hours	≈14 h per sale line
5	Dock utilization (receive plan)	`scheduled ÷ (doors × hours × rate) = 130 ÷ (10 × 16 × 1.0)`	booklet CAP-D formula; illustrative inputs	81.3% (< ~85%)
6	Putaway labor on the receipt	`hours = units ÷ UPH × gross-up = 240 ÷ 120 × 1.2`	booklet CAP-B formula; illustrative inputs	2.4 h
7	Device dependency as planned	`effort estimate 3–4 days; what-if plans = 0`	record (Apple G2)	single-point dependency

Table 2 — the fix: latency rules, device gate and the cutover-night runbook, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Suppression rule	`if (now − WMS as-of) > 15 min: publish(node) = last-good, flag = stale; commits still apply`	record design	oversell exposure from floor loss → 0 beyond 15 min
2	Republish budget	`p95(t_publish − t_event) < 60 s`	record design	60 s
3	Settlement budget	`unmatched age > 24 h → flag; > 48 h → Sev`	record design	24 h / 48 h
4	Device gate	`devices proven ÷ devices in fleet = 100% before training entrance; PoC before cutover week`	record (Apple G2 p45)	proven, not promised
5	Runbook size	`48,885 task-min ÷ 60 = 814.75 h over 343 tasks → 142.5 min per task average`	record / derived	≈815 h; ≈2.4 h/task
6	Cutover night (illustrative clock, record steps)	`T−72 h freeze in-transit → 20:00 MCS closing extract by bucket → 21:30 S/4 opening MB52 → 22:00 ISM seed (opening buckets incl. unposted ship confirms = opening SNB) → 22:30 R10: Σ per bucket across three columns = 0 difference → 23:00 clear negatives → 23:30 transfer AFS to Uncommitted → 00:30 scan-and-reserve → 01:00 zero-then-publish (irreversible) → 01:05 OMS reads ISM → triggers armed → 06:00 first drift`	record steps (Apple D1 freeze; GFiber R10; Packet 3 U5); clock illustrative	one irreversible instant
7	Trigger 1 exposure	`events/h × (1 − 0.99) × 4 h = 1,000 × 0.01 × 4`	record trigger; illustrative volume	> 40 unapplied events over 4 h fires rollback
8	Trigger 2	`p95 > 2 × 60 s = 120 s for 60 consecutive min`	record trigger	120 s × 1 h
9	Double-publish invariant	`published locations per SKU at any instant = 1; Σ AFS(before) = Σ AFS(after)`	record (R10; U5)	0 double publish

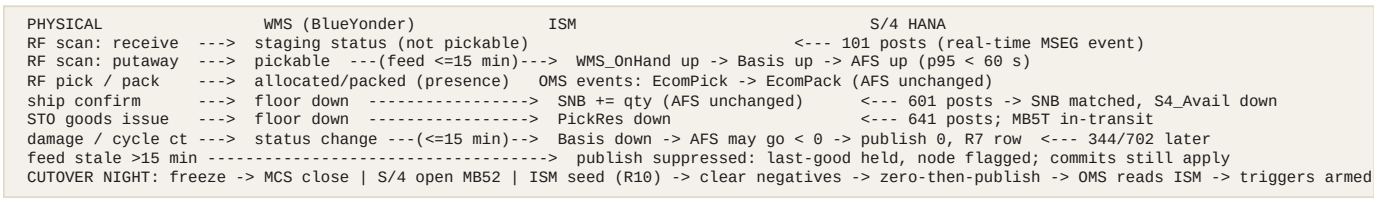

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Stale-floor behavior	compute on last count	hold last-good, flag node, commits still apply	record design
2	Device readiness	promised; script failed; training +1.5 weeks	entrance criterion; PoC before cutover week; no repeat	record
3	Mock reconciliation	7.0%	1.8% → 0.3% (vs 0.5%)	record (S18)
4	Rollback	—	armed twice, never fired	record
5	Customer-facing incidents	recurring oversell	0 through both go-lives	record
6	Go-live date	at risk from the device slip	held	record

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Runbook effort	`814.75 h × $110 = $89,622.50`	record hours; illustrative rate	≈$90K
2	S18 budget outcome	`$1,800,000 × 3% = $54,000 under`	record ~3%; derived $	≈$54K
3	Stale-hour exposure without suppression	`12 EA × $30 = $360 per SKU-hour of floor loss`	illustrative	$360
4	S18 pipeline behind the date	`$20M ÷ 8 months = $2.5M/month average`	record $20M; derived division — "not banked"	≈$2.5M/month (the S18 noun)
5	Protected headline (S1)	`$1,000,000 anchor + $1,530,000 modeled`	user anchor + modeled	≈$2.5M/yr (the S1 noun)

SOLUTION FLOW — THE SYSTEM & DATA MAP (LATENCY VIEW)

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Sell rate on the SKU (EA/h) × 15-min window	4 → 1 EA	12 → 3 EA	40 → 10 EA

INPUT	LOW	BASE	HIGH
Feed budget	5 min → 1 EA at base rate	15 min → 3 EA	60 min → 12 EA
Dock utilization (130 trailers)	12 doors → 67.7%	10 doors → 81.3%	8 doors → 101.6% (dwell nonlinear)
Putaway UPH on 240 EA (×1.2)	200 → 1.44 h	120 → 2.4 h	60 → 4.8 h
Trigger 1 at 99% × 4 h	500 ev/h → 20	1,000 → 40	5,000 → 200 unapplied events

SPOKEN STATEMENT

"From the infrastructure seat the program was four physical cadences meeting one published number. I wrote the budgets as numbers: the floor feed inside fifteen minutes or the engine holds the last good value and flags the node — it will under-sell for minutes and never over-sell; republish within sixty seconds; store settlement nightly with a day's flag and two days to a Sev. Every physical event maps to one bucket — a receipt waits for putaway, a commit moves the number in a minute, a pick, pack or ship moves units between buckets and leaves it alone, a loss on the floor moves it instantly. I had missed a device dependency on the earlier migration — a three-day script that failed on new hardware and slipped training a week and a half, date held — so device readiness became an entrance criterion and a proof-of-concept ran before cutover week. The cutover was 343 tasks, about 815 hours, one irreversible instant, rollback triggers armed twice and never fired, zero customer-facing incidents."

IF CHALLENGED

"The device story is a different program — why is it here?"

Because it is the same DC family and the lesson is the record of how the ISM cutover was planned: Apple G2 says the what-if rule became the UDC RF-device proof-of-concept before cutover week. I keep the programs separate — the miss is S18's, the proof-of-concept is UDC's — and I say so.

"Your clock times for cutover night are invented."

The clock is illustrative; the steps and their order are record — freeze, three-column balance, clear negatives, transfer to Uncommitted, scan-and-reserve, zero-then-publish, triggers armed, first drift at T+1. I would not quote the hours.

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
What happens when the floor and the system disagree?	Insist on the Highest Standards	Suppress, hold last-good, flag; tolerance zero at T+1.	Never "we trusted the WMS."
Tell me about a go-live that went wrong.	Are Right, A Lot	Device script: effort vs impact; +1.5 weeks; date held; permanent rule.	Never "100 of 400"; never a cost multiplier.
Tell me about acting fast with incomplete information.	Bias for Action	Stale node on the wall: re-read, not re-promise — rule pre-decided.	Do not dramatize; it was a rule firing.
How do you run a cutover?	Deliver Results	343 tasks, one irreversible instant, priced triggers, never fired.	Do not quote the clock times as record.

BEHAVIORAL PACK — FOUR SEPARATE 90-SECOND STAR ANSWERS, EACH FROM A DIFFERENT MOMENT OF THE STORY

NEW

INSIST ON THE HIGHEST STANDARDS · AIQB Q1 **Q1. "Describe a time when you refused to compromise your standards around quality/customer service, etc. Who was your customer? What was the result?"**

The compromise on offer was to keep publishing availability from the last warehouse count when the floor feed went stale. The customer was the dotcom shopper who gets a "yes" we then cannot ship. I wrote the rule the other way: if the floor feed is older than fifteen minutes, the engine holds the last good number for that node, flags it, and keeps applying order commits — so it can under-sell for a few minutes and can never over-sell against a floor that may have lost units. The cost is lost sales during a stale window — on a SKU selling twelve an hour that is three units per fifteen minutes — and more flags for Inventory Control to read. The same posture is the drift tolerance: zero, a difference between books is a Sev. The result is two go-lives with zero customer-facing incidents and a stale node that under-sold for minutes and never over-sold.

Number to land: 15 min; 3 EA per stale window at 12/h (illustrative); drift 0 · **Pivot to NACF:** I would hold the same line between receive scan and available: not stowed, not promisable, whatever the dashboard says. · **Do NOT say:** that suppression was free; that the sell rate is program data.

ARE RIGHT, A LOT · AIQB Q4 **Q2. "We don't always make the right decision all the time. Tell me about a time when you made a bad decision. What was the impact of that decision? What did you learn?"**

On the WMS migration I planned a device conversion as a three-to-four-day task, low effort, low attention — and that was the bad decision. Training sign-off was a go-live exit criterion gated on hundreds of RF guns, printers and workstations converting. I scheduled a device test with engineering days before training just to be sure, and the upgrade script failed: the fleet had new RF devices that did not run the old code. With key people on night shifts, manual conversion could not finish in time. I told leadership straight: training slips a week and a half, my miss. The root cause was not the script; it was my risk model — I had scored the task by effort, not impact, so a single-point dependency in front of an exit criterion had no what-if plan. The rule changed permanently: every cross-functional dependency gets a what-if and a fallback regardless of effort, and device readiness moved into training's entrance criteria — proven devices, not promised ones. The go-live date held, the program landed about three percent under its $1.8M budget, and on the next DC an RF-device proof-of-concept ran before cutover week.

Number to land: +1.5 weeks; date held; ~3% under ~$1.8M · **Pivot to NACF:** FC launches are chains of small dependencies — a label printer, a firmware level, a dock appointment system — impact decides attention, never effort. · **Do NOT say:** "100 of 400" (sources disagree — say "hundreds"); any "x cheaper" multiplier.

BIAS FOR ACTION · AIQB Q4 **Q3. "Tell me about a time when you had to gather information and respond immediately to a situation. What was the outcome?"**

On the cutover wall a node's floor feed aged past fifteen minutes while orders were flowing. The information I needed was already on the wall because we had designed it to be there: the feed as-of time per node, the stale flag, the publish log, and the drift and OOB rows from the last cut. The engine had already done the first thing — suppressed publish for that node and held the last good number. The decision in the room was whether to re-promise from the S/4 book instead; I said no, because the book is above the floor by whatever shipped since the last snapshot, and promising from it is exactly the oversell we had designed out. We re-read when the feed returned, let the Negative AFS report tell us if any commit had landed on lost stock — none had — and logged the event. The outcome was a few minutes of under-sell on one node, no customer impact, and a runbook line for next time. The speed came from deciding the rule when nobody was tired.

Number to land: 15-min budget; exposure ≤ sell rate × window; 0 negatives at T+1 · **Pivot to NACF:** On a launch night the decision rules — what we hold, what we never promise — should be written before the first trailer. · **Do NOT say:** that I overrode the engine; that the episode's duration is record.

DELIVER RESULTS · AIQB Q2 **Q4. "Tell me about a time when you had significant, unanticipated obstacles to overcome in achieving a key goal. Were you eventually successful?"**

The goal was two go-lives — January planning, May execution — with zero customer-facing incidents and a peak freeze behind them; the obstacle was that cutover moved a live publish across about a dozen impacted systems with one instant that could not be undone. I ran it as a 343-task runbook, about 815 task-hours, each task with an owner, a duration and a predecessor, inside a transfer freeze so in-transit converted as its own batch. The night had a three-column balance — MCS closing, S/4 opening, ISM seed — that had to agree per bucket before anything moved; then clear negatives, transfer to Uncommitted, scan-and-reserve, and zero-then-publish so no SKU was ever promisable from two places. Rollback triggers were numbers per interface — sync under 99% for four consecutive hours or publish p95 over twice budget for an hour — armed for both go-lives. They never fired. First drift at T+1 was zero; hypercare exited at under two blockers a day in week three of four. Successful, and the obstacle I would plan harder for next time is the device fleet.

Number to land: 343 / ≈815 h / armed twice, never fired / drift 0 at T+1 · **Pivot to NACF:** An FC go-live runbook with one named irreversible step and priced stop conditions is the same artifact. · **Do NOT say:** cutover clock times as record; "the 836-row log" as ISM's — it is the umbrella program's.

SAME STORY, THREE ANGLES — DATA · CONFLICT/INFLUENCE/BACKBONE · FAILURE-LEARNING NEW

DATA ANGLE · DIVE DEEP	CONFLICT / INFLUENCE ANGLE · HAVE BACKBONE	FAILURE / LEARNING ANGLE · ARE RIGHT, A LOT
"Latency per node, per hour, per event type — receipts slowest, goods issues fastest." **Headline metric:** ≤ 15 min feed; p95 < 60 s; 100-min dock-to-stock (illustrative) Event × node × minute grain; the stale-node flag and publish log were the data. Revealed: a stale feed only hurts on the floor side; commits keep flowing. Honest limit: the sell rate and clock are illustrative.	*"Suppress publish on a stale node — and accept the lost sales."* **Headline metric:** under-sell ≤ 3 EA per window vs oversell $30/unit Dotcom wanted the number to keep moving; I priced the asymmetry and leadership accepted suppression. Influence: a rule in the FSD and a flag on the wall, not a debate at 01:00.	*"Effort is not impact."* **Headline metric:** training +1.5 weeks; date held The device script (Apple G2) — scored by effort, no what-if. Do differently: what-if per dependency from kickoff; device compatibility verified at refresh. Proof it stuck: UDC RF-device PoC before cutover week; mocks 7.0 → 1.8 → 0.3%.

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS, WITH NUMERIC ANSWERS NEW

Definitional — the ship confirm and the 601 are minutes apart. In that gap, where is the unit?

Off the floor, inside S/4 Available, and inside SNB at the DC node. Floor 1,090 + SNB 130 = 1,220 = the netted floor; S/4 still 1,240; Basis 1,220; buckets 550; AFS 670 — unchanged. When the 601 posts, S/4 goes to 1,150 and SNB to 40 together; AFS still 670. The unit is never in two promisable places and never in none.

Say: *"Between ship confirm and goods issue the unit sits in Shipped-Not-Billed — subtracted from the promise, still in Finance's book — and AFS does not move."*

Why "hundreds" of devices — don't you know the number?

Two of my own source documents disagree — one says about 400, the other about 100 — so I say "hundreds" and the estimate was three to four days. The count is not the lesson; the missing what-if plan is.

Say: *"Hundreds of devices, a three-to-four-day estimate, and no what-if plan — that last part was mine."*

Your triggers never fired — how would you know they worked?

They were exercised in the mocks against the 0.5% tolerance and the sync and p95 series were on the wall in real time; a trigger that is observable and armed is a working control even when it does not fire. If I had seen sync under 99% for four hours, consumers would have reverted to the prior publish — a tested path, not a hope.

Say: *"Armed and observable for both go-lives; never needed — that is the outcome I wanted, and the mocks are why."*

20-SECOND VERSION + NACF BRIDGE NEW

20-second version. From the infrastructure seat the availability program was four physical cadences meeting one published number: floor feed inside fifteen minutes or publish is held and flagged, republish under a minute, every physical event mapped to one bucket, devices proven before training after I missed one, and a 343-task cutover with one irreversible instant and rollback triggers armed twice and never fired — zero customer-facing incidents.

NACF bridge. NACF's version is dock-to-stock as the promisability lever — dock doors × hours × unload rate capped near 85% utilization, putaway hours = units ÷ UPH — and a rule that received-not-stowed is never promisable; plus a launch runbook with device readiness in the entrance criteria and stop conditions written as numbers before the first trailer.

Safe-say box. "A stale floor feed means we hold the last good number and flag the node — we under-sell for minutes and never over-sell." · "The device miss is the earlier WMS migration's; the proof-of-concept before cutover week is how it changed the next one — hundreds of devices, a week and a half on training, the date held."

S3-R — End to end: Shipped-Not-Billed and the one Financial On-Hand — a store sale that S/4 will not see until tonight, de-aggregated back to the line and the cent, so Finance and Supply read one on-hand and the failure direction is always safe NEW

LPs this story serves here: Earn Trust (primary — Finance keeps its own reconciliation → Finance owns the aging report) · Customer Obsession (decrement at the sale, not at the posting) · Ownership (the product is Finance running it without me) · Dive Deep (match rate and aging as the metric that proves it)
Process family: Deliver / Finance — sold-not-posted control: SNB ledger, aggregate-posting match, COGS de-aggregation, one Financial On-Hand, month-end tie

Honesty label. Record mechanism (GFiber v8 S3, Amazon master S3): SNB incremented by POS flash sale, OMS omni pending sale and WMS ship confirm; decremented only on a matched S/4 aggregate posting; match Aggregation# ↔ store header ↔ lines; park unless Σq_i = q_P; duplicate header dropped by key; > 24 h flag, > 48 h Sev; COGS_i = C_P × q_i ÷ q_P with the last line absorbing rounding so Σ ties to the cent; SNB ≥ 0 always; FOH published by ISM, ties to MB5L at month-end; cost (WAC) stays S/4-owned, ISM visibility-only. User anchor (GFiber v8 only): "Financial On-Hand truths 2 → 1"; FSD signed 6/5/25; match rate ≥ 99.5% within 24 h is a *design target*, not a result; days-to-tie at month-end not in record. Modeled: ≈$0.6M/yr (cancels $450,000 + reconciliation $141,440 + close $48,960 = $640,400) — "the record has no drift dollar"; the cancel-rate row borrows S1's 0.10% benchmark, so if the room wants one number keep S1's and drop it. Illustrative: the store 0101 walk (60 → 48), the 12-unit / $300.00 posting, the $100.00 three-line split. I owned the identity, the match rule, the aging tolerance and the audit path; the ISM and S/4 teams built the feeds, the matcher and the screens; Inventory Accounting runs the aging report.

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH

Earn Trust. Finance said "we keep our own reconciliation"; I showed them the same on-hand arriving from the physical side first and gave them the aging report to own — two truths became one.

Customer Obsession. A store sale S/4 would not see until the nightly aggregate was a unit dotcom could still promise; I moved the decrement to the moment of sale.

Ownership. The exit bar was not "the matcher works" but "Inventory Accounting runs the unmatched-aging report without me."

Dive Deep. The failure direction is provable: an unmatched posting keeps SNB high, so AFS_reported ≤ AFS_true in every unmatched state — under-sell, never over-sell.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. S/4 posts store sales the way an ERP should — as a nightly aggregate, one quantity and one cost per aggregation number — while the stores sell all day. In that window a sold unit was still "available" to dotcom, and Finance and Operations each kept their own on-hand because neither trusted the other's timing. **Task.** Make the sold-but-not-posted units visible to the promise in real time, tie the aggregate posting back to the lines and the cents, and publish one Financial On-Hand both orgs read. **Action.** I defined Shipped-Not-Billed as its own bucket: incremented at the store ring, the omni pending sale and the DC ship confirm, keyed so a replay is a no-op; decremented only when the S/4 aggregate posting matches — aggregation number to store header to lines, parked unless the line quantities sum to the posting quantity. The matcher pro-rates the posting's cost back to each line — cost times line quantity over posting quantity, last line absorbs the rounding, so a $300.00 posting over twelve units in five lines is 75, 50, 100, 25, 50 to the cent. Financial On-Hand is published once from ISM — Available plus merchandise reserve plus lost-and-found, with SNB as its own column — and ties to MB5L at month-end; cost stays S/4-owned. The failure direction is safe by construction: a posting that will not match keeps SNB high and under-states the promise. **Result.** Primary metric: Financial On-Hand truths two to one, Finance reading the number from ISM and owning the aging report; over-sell from unmatched postings zero by design; about $0.6M a year modeled, record carries no drift dollar.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — A store rings three units at 10:02; S/4 learns of it at the nightly aggregate. Until then the book says the units are on hand, dotcom's old computation said they were promisable, and Finance's bridge spreadsheet tried to reconcile what Operations counted against what S/4 posted. Two Financial On-Hand truths, a phantom-availability window the length of a business day, and a month-end that closed on a bridge.

T — Give sold-not-posted units a bucket that moves at the sale and clears only on a matched posting; de-aggregate the posting to the line and the cent for the data platform; publish one FOH that Finance accepts and that ties to MB5L; hand the exception report to Finance to own.

Baselines on the table: FOH truths 2 · phantom window W = t_post − t_sale ≈ a business day (illustrative) · Finance bridge ≈ 32 h/week (benchmark) · month-end tie-out +1 day (benchmark) · match-rate design target ≥ 99.5% within 24 h · SNB ≥ 0 always.

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery** — where every sold-not-posted unit comes from (POS flash sale, omni pending sale, ship confirm) and how S/4 posts it (aggregate, Aggregation#, qty, COGS); who reads on-hand and from where. *Exit bar:* every sold-not-posted path named; Finance's bridge spreadsheet documented as the baseline.

- **Plan & Design (inside the ISM FSD chain; signed 6/5/25 — user anchor)** — SNB ledger definition; match rule; de-aggregation rule; failure-direction statement; FOH equation; control owner per bucket. *Exit bar:* Finance accepts one FOH; WAC confirmed S/4-owned, ISM visibility-only.
- **Build & Test** — matrix families: SNB increment/decrement/reversal, de-aggregation, duplicate header, late line; Inventory Accounting's UAT entrance "every SIT case ties to the cent." *Exit bar:* Σ per-line COGS = posting COGS to the cent in every cell; SNB never negative in any cell.
- **Cutover & Go-Live (January; May)** — opening SNB seeded from unposted ship confirms (R10); publish FOH and SNB back to S/4 visibility. *Exit bar:* aging report empty or explained at T+1; no negative SNB; Finance reads FOH from ISM.
- **Hypercare / Close** — aging report read daily; month-end FOH tie to MB5L through the ISM number, not a bridge. *Exit bar:* aging report owned by Finance without me; month-end ties (mechanism canonical; days-to-tie not in record).

Influence and ownership. Mine: the identity, the match rule, the aging tolerance, the audit path, the UAT entrance bar. ISM and S/4 teams built the feeds, matcher and screens; Inventory Accounting owns the aging report and the settlement side; Store Systems own the POS feed.

> **Designed the process; others own it now.** Inventory Accounting runs unmatched-aging; the EDW carries per-line COGS with Aggregation# lineage. **Trade-off put to leadership:** a posting that will not match under-states the promise until it is fixed (visible over-ordering by Replenishment) — accepted, because the other direction is a customer defect.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY

- **$** — ≈$0.6M/yr modeled: cancels 30,000,000 × 0.10% × $15 = $450,000; reconciliation 32 h/wk × 52 × $85 = $141,440; close 6 people × 8 h × $85 × 12 = $48,960; total $640,400. The record has no drift dollar.
- **#** — FOH truths 2 → 1 (user anchor); 3 increment sources, 1 decrement path; 5 lines / 12 units / $300.00 tie to the cent (illustrative).
- **%** — match-rate design target ≥ 99.5% within 24 h; over-sell from unmatched postings 0% by construction.
- **Time** — AFS decrement moved from t_post (nightly) to t_sale (real-time); > 24 h flag, > 48 h Sev; month-end tie through ISM.
- **Customer** — the phantom-availability window closed: a unit sold at 10:02 is off the promise at 10:02.
- **Quality** — SNB ≥ 0 always; Σ per-line COGS = C_P to the cent; FOH_ISM − FOH_S4 = 0 at month-end per SKU × node (design).

L6 LEVEL EVIDENCE — every line is this story's record or labeled model, no new canon numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	Two orgs, two on-hands, no shared definition of "sold"; I defined the bucket and the match.
Scope & influence	Finance, Inventory Accounting, Store Systems, Digital and the ISM/S/4 teams; the FSD signature was the lever.
Execution trade-off + mechanism others own	Under-state on unmatched rather than guess; the mechanism others own: the aging report.
Impact	FOH truths 2 → 1; Finance closes on the ISM number; phantom window closed.
Process improvement	Bridge spreadsheet retired by giving its owner the real report.
Complexity & consensus	Three increment sources, one decrement path, cents that must tie, two orgs that had to agree.
Root cause at scale	Drift surfaces on the aging report, never inside the FOH number — late line, header-as-lines, return without original.

PROBING — FIVE FACETS, THEN THE HARDEST FOLLOW-UPS NEW

THE FIVE FACETS — WHERE EACH ONE LIVES IN THIS STORY

1 · Data analysis. Grain: SKU × node × sales-event line, rolled to Aggregation# for the match; FOH at SKU × node × day. Data: Aptos RetailSaleTransactions (Txn × line × store), OMS Tlog / ShipmentConfirmation lines, S/4 aggregate posting (Aggregation#, qty, COGS; stock side 601 in MATDOC, FI side ACDOCA). Cuts: unmatched by age, by cause (late line, header-as-lines, return without original), by store. Revealed: the phantom window was cadence, not error — so the fix is where the decrement happens, not a faster batch.

2 · Solution design. Options: (A) faster S/4 posting — rejected, still a window and S/4 posts aggregates by design; (B) let dotcom read POS directly — rejected, a second computation; (C) an SNB bucket inside the one AFS identity, cleared only on a matched posting, with FOH published once — chosen. Inside C: partial-match vs park-unless-equal — park chosen (failure direction safe).

3 · Math & data logic. SNB(t) = Σ sold-or-shipped-not-posted − Σ matched; COGS_i = C_P × q_i ÷ q_P, last line absorbs rounding; W = t_post − t_sale; AFS_reported ≤ AFS_true for all unmatched states; match_rate = matched ÷ received per day. Worked below on store 0101.

4 · Implementation. Phases above; opening SNB seeded at cutover from unposted ship confirms; Finance UAT entrance "ties to the cent"; aging report handoff. Risks: late POS lines, duplicate headers, returns without originals.

5 · Probe questions. Below: why isn't SNB in on-hand; what if S/4 posts 12 and ISM saw 10 lines; why quantity pro-rata; who owns cost; and the trap drills.

FACET 5 — PROBE QUESTIONS (CHALLENGE Q&A TUNED TO THIS INTERVIEWER)

Infra — why isn't Shipped-Not-Billed in on-hand?

It is in Finance's book and out of the promise. Until the posting, S/4 Available still contains the sold unit — so Financial On-Hand, which starts from Available, already carries it; SNB is shown as its own column so Finance sees what tonight's posting will remove. AFS subtracts SNB because the unit is gone from the promise the moment it is sold. After the match, Available falls by the matched quantity and SNB falls by the same — the two books agree and SNB is back to zero.

> **Infra — S/4 posts 12 units; ISM has seen only 10 lines. What happens?**
> Park the posting — the rule is match only when Σq_i = q_P. SNB stays at 10, S/4 Available has already dropped by 12, so AFS is under-stated by 10 until the two lines land; the unmatched-aging report shows it at 24 hours and makes it a Sev at 48. I never partial-match to force a zero, because the two missing lines may be a different store's or a return without its original.

> **Infra — why pro-rate cost by quantity? Lines can carry different prices.**
> Price, yes; cost, no — the posting is per SKU, so every unit in it carries the same cost and quantity pro-rata is exact cost pro-rata. Price lives on the sales line, not the posting. The only arithmetic risk is rounding, and the last line absorbs it so the sum ties to the cent.

> **Infra — who owns cost?**
> S/4. Moving-average cost (MBEW-VERPR) is S/4's; ISM displays it and multiplies it for the MB5L tie. A value difference at month-end is a WAC question for Finance, never an ISM edit. Tolerance on units is zero.

BUSINESS IMPACT MODEL — KPI DRIVERS, BASELINE → AFTER

DRIVER	BASELINE	AFTER	$ / YR	BASIS
Financial On-Hand truths	2 (Finance vs Ops)	1 shared FOH	—	user anchor (FSD 6/5/25)
AFS decrement point	at S/4 posting	at sale / ship	—	record mechanism
Phantom-availability cancels	~0.10 pt of orders	~0	≈$0.45M	modeled (30M × 0.10% × $15)
Finance reconciliation hours	32 h/wk bridge	~0	≈$0.14M	modeled (32 × 52 × $85)
Month-end close, inventory tie-out	+1 day bridge	ties to MB5L	≈$0.05M	modeled (6 × 8 h × $85 × 12)
Total modeled	—	—	≈$0.6M/yr	record has no drift dollar

THE CALCULATION WALK — ONE STORE, ONE SKU, ONE DAY, ONE POSTING NEW

Setup (illustrative). SKU 12345 at store 0101 (no WMS floor, so Basis = S4_Avail; no MerchRes at a store). Opening after the 06:00 snapshot: S/4 Available 60; SNB 0; AFS 60. Five sales during the day — 3, 2, 4, 1, 2 units — one nightly aggregate posting P with q_P = 12 and C_P = $300.00.

Table W1 — the day at the store: ring → SNB → AFS, then the posting.

#	TIME · EVENT	S4_AVAIL	BASIS	SNB	AFS = BASIS − SNB	NOTE
F0	06:00 snapshot	60	60	0	60 − 0 = 60	store: Basis = S4_Avail
F1	10:02 POS rings 3 EA (Kafka line, key POS × Txn × line)	60	60	0 + 3 = 3	60 − 3 = 57	republished < 60 s
F2	10:04 the same transaction replays	60	60	3 (no-op by key)	57	R9: duplicate dropped
F3	11:15 · 13:40 · 15:05 · 16:30 rings of 2, 4, 1, 2	60	60	3 + 2 + 4 + 1 + 2 = 12	60 − 12 = 48	physical on shelf = 48
F4	17:00 watermark (pre-posting): Finance reads FOH columns	60	60	12	48	Avail 60 · SNB 12 · physical 48 — one row, both orgs
F5	23:30 S/4 aggregate posting P: Aggregation# A-1, q_P = 12, C_P = $300.00	60 − 12 = 48	48	12 − 12 = 0 (Σq_i = 12 = q_P → match)	48 − 0 = 48	AFS unchanged across the posting
F6	T+1 06:00 drift	48 = MB52 48	48	0	48	Drift = 48 − 48 = 0

Table W2 — de-aggregation to the cent (COGS_i = C_P × q_i ÷ q_P; last line absorbs rounding).

LINE	Q_I	FORMULA → SUBSTITUTION	COGS_I	RUNNING Σ
1	3	300.00 × 3 ÷ 12	75.00	75.00
2	2	300.00 × 2 ÷ 12	50.00	125.00
3	4	300.00 × 4 ÷ 12	100.00	225.00
4	1	300.00 × 1 ÷ 12	25.00	250.00
5 (last)	2	300.00 − 250.00 (absorbs rounding; nominal 50.00)	50.00	300.00 ✓ = C_P
Rounding case A	1, 1, 1	C_P = $100.00: 100 ÷ 3 = 33.333… → 33.33, 33.33, last = 100.00 − 66.66	33.33 · 33.33 · 33.34	100.00 ✓
Rounding case B	3, 2, 2	C_P = $100.00: 100 × 3 ÷ 7 = 42.857 → 42.86; 100 × 2 ÷ 7 = 28.571 → 28.57; last = 100.00 − 71.43	42.86 · 28.57 · 28.57	100.00 ✓

Table W3 — what goes wrong, one variant per control.

CONTROL	VARIANT	FORMULA → SUBSTITUTION	CAUGHT BY · OWNER	EFFECT
R8 park rule	One 2-unit line has no header key; 10 of 12 match	`matched 10 → SNB 12 − 10 = 2; S4_Avail 48; AFS = 48 − 2 = 46 vs truth 48`	unmatched-aging > 24 h · Inventory Accounting	−2 (under-sell, safe)
R8 park rule (whole posting)	ISM has seen 10 lines; S/4 posts 12	`Σq_i 10 ≠ q_P 12 → park; SNB 10; S4_Avail 48; AFS = 48 − 10 = 38 vs truth 48`	aging; Sev at 48 h	−10 (safe)
R9 duplicate header	Posting A-1 arrives twice	`match set already closed → rejected; SNB stays 0; a decrement beyond matched quantity is rejected → SNB never −12`	R9 · ISM app team	0
SNB ≥ 0	A return line lacks its original	`decrement attempt on SNB 0 → rejected and alerted; line to aging report`	R3/R8	0
Cents tie	Naive rounding on case A	`33.33 × 3 = 99.99 ≠ 100.00 → UAT cell fails; last-line rule → 100.00`	Inventory Accounting UAT entrance	0.01 caught

THE MATH — FOUR-TABLE DERIVATION (DOLLARS; FORMULA → SUBSTITUTION → RESULT) NEW

Table 1 — before.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	FOH truths	`Finance book + Ops count`	user anchor	2
2	Phantom window	`W = t_post − t_sale = 23:30 − 10:02`	illustrative	≈13.5 h
3	Cancels from phantom availability	`30,000,000 × 0.10% × $15`	modeled; CS $5–8 + refund + margin share	$450,000
4	Finance bridge labor	`32 h/wk × 52 × $85`	benchmark	$141,440
5	Month-end tie-out	`6 × 8 h × $85 × 12`	benchmark	$48,960

Table 2 — the fix.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Decrement point	`AFS(10:02) = 60 − 3 = 57 (was 60 until 23:30)`	record mechanism	W → 0
2	Match	`Σq_i = 3 + 2 + 4 + 1 + 2 = 12 = q_P → SNB 12 → 0; S4_Avail 60 → 48`	record rule	48 = 48
3	De-aggregation	`75 + 50 + 100 + 25 + 50 = 300.00 = C_P`	record rule	ties to the cent
4	Match-rate KPI	`matched ÷ received per day ≥ 99.5% within 24 h; at 2,000 postings/day → ≤ 10 unmatched`	design target	≤ 10/day
5	Failure direction	`unmatched ⇒ SNB high ⇒ AFS_reported ≤ AFS_true`	record statement	under-sell only

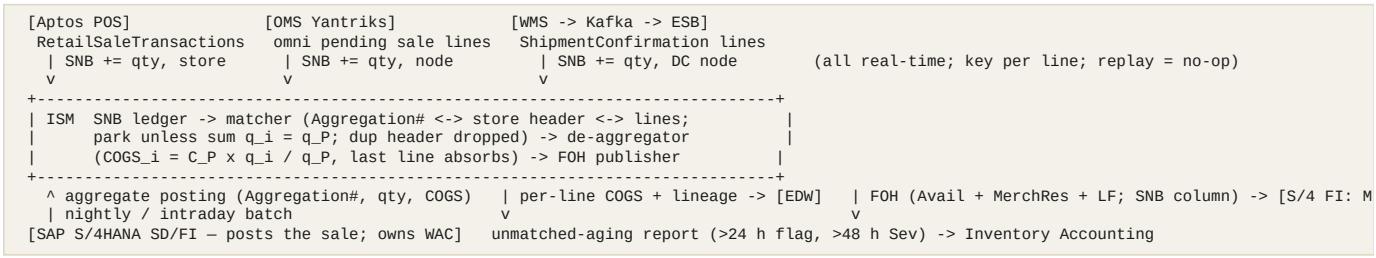

Table 3 — after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	FOH truths	2	1	user anchor
2	Decrement point	t_post	t_sale	record
3	Over-sell from unmatched postings	possible	0 by construction	record design
4	Finance bridge	32 h/wk	~0; aging report owned by Finance	benchmark / record
5	Month-end	bridge, +1 day	ties to MB5L through ISM	record mechanism; days not in record

Table 4 — the dollars.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Cancels avoided	`30,000,000 × 0.001 × $15 = $450,000`	modeled	$0.45M
2	Reconciliation labor	`32 × 52 × $85 = $141,440`	modeled	$0.14M
3	Close	`6 × 8 × 85 × 12 = $48,960`	modeled	$0.05M
4	Total	`450,000 + 141,440 + 48,960 = $640,400`	modeled; record has no drift dollar	≈$0.6M/yr
5	Double-count guard	`if S1's $0.9M oversell row is on the table, drop row 1 here → $190,400`	rule	≈$0.2M

SOLUTION FLOW — THE SYSTEM & DATA MAP

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Postings a day × 0.5% unmatched allowance	1,000 → 5	2,000 → 10	5,000 → 25
Cancel rate (30M × $15)	0.05% → $225K	0.10% → $450K	0.25% → $1.125M
Bridge hours/week × 52 × $85	16 → $70,720	32 → $141,440	48 → $212,160
Modeled total	≈$0.35M	≈$0.64M	≈$1.39M
Late line size on a 12-unit posting	1 → AFS −1	2 → −2	whole posting → −10 (parked)

SPOKEN STATEMENT

> "S/4 posts a store's sales as one nightly aggregate — one quantity, one cost. The stores sell all day. So I gave the sold-but-not-posted units their own bucket, Shipped-Not-Billed: up at the ring, the omni sale and the ship confirm, keyed so a replay is a no-op; down only when the aggregate posting matches — aggregation number to header to lines, parked unless the quantities sum. Three units rung at 10:02 are off the promise at 10:02, not at 23:30. The matcher pro-rates the posting's cost back to each line — cost times line quantity over posting quantity, last line absorbs the rounding — so $300 over twelve units in five lines is 75, 50, 100, 25, 50, and $100 over three lines is 33.33, 33.33, 33.34. Financial On-Hand is published once from ISM, with SNB as its own column, and ties to MB5L at month-end; cost stays S/4's. If a posting will not match, SNB stays high and we under-sell — never over-sell. Two Financial On-Hand truths became one, Finance owns the aging report, and the dollar view is about $0.6M a year, modeled."

IF CHALLENGED

> **"The cancel rate is borrowed from S1 — double-counted?"**
>
> Different window: S1's rate is the vocabulary problem across node types; this is the posting-lag window inside one node. If the room wants one number, I keep S1's and drop this row — the mechanism still stands on the record.

> **"32 hours of Finance time — source?"**
>
> Benchmark, not record. The record is the mechanism: the bridge spreadsheet died when its owner owned the real report. A two-week time study on Inventory Accounting prices it properly.

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Tell me about getting two functions onto one number.	Earn Trust	Same on-hand from the physical side first; Finance owns the aging report.	Never say Finance was wrong to keep a bridge.
A time you put the customer first in a system design.	Customer Obsession	Decrement at the sale; under-sell is the only failure direction.	Never claim a measured cancel reduction.
What did you hand off, and how did you know it stuck?	Ownership	Aging report run by Inventory Accounting without me; month-end ties through ISM.	Days-to-tie is not in the record.
A metric you created.	Dive Deep	Match rate within 24 h and SNB aging p95 — design targets with owners.	Never present 99.5% as a result.

BEHAVIORAL PACK — FOUR SEPARATE 90-SECOND STAR ANSWERS, EACH FROM A DIFFERENT MOMENT OF THE STORY NEW

EARN TRUST · AIQB Q5 **Q1. "Tell me about a time when your team's goals were out of alignment with another team you relied on in order to meet your goal. How did you work with the other team?"**

My goal was one published on-hand; Finance's goal was a close they could defend, and their answer was "we keep our own reconciliation." They were not wrong to distrust Operations' timing — S/4 saw a store sale only at the nightly aggregate, and anything before that was somebody's spreadsheet. So instead of asking them to trust a new number, I showed them the same number arriving from the physical side first: the store ring adds to Shipped-Not-Billed at 10:02, S/4 Available stays 60 until the posting, and the Financial On-Hand row they read carries both columns — 60 and 12 — so they can see tonight's posting before it happens. Then the posting matches and both columns move together: 48 and 0. What made it theirs was the exception path: anything that will not match ages on a report with a 24-hour flag and a 48-hour Sev, and Inventory Accounting owns that report. Their UAT entrance was "every SIT case ties to the cent," and it did. Two truths became one because the bridge spreadsheet's owner got the real report.

Number to land: FOH truths 2 → 1; 60 / 12 → 48 / 0 · **Pivot to NACF:** When Finance and Ops disagree on inventory at an FC, I would show the physical event first and give Finance the exception report to own. · **Do NOT say:** that Finance resisted change — they had a real control need; the signing-org names (user anchor).

CUSTOMER OBSESSION · AIQB Q8 **Q2. "Tell me about a time when you had to balance the needs of the customer with the needs of the business. What did you do? What was the result?"**

The business need was an ERP that posts sales as a nightly aggregate — correct, auditable, and slow; the customer need was that a unit sold in a store at 10:02 stop being promisable online at 10:02. I did not fight the ERP; I added a bucket in front of it. Shipped-Not-Billed increments in real time at the ring, so AFS at the store goes 60 to 57 within the sixty-second publish budget, and the nightly posting later clears it without moving AFS at all — 48 before, 48 after. The balance point was the failure direction: when a posting will not match, I chose to leave SNB high and under-sell rather than guess and over-sell — the business sees a little over-ordering by Replenishment, the customer never sees a cancel. The modeled value is about $450,000 a year of phantom-availability cancels on an illustrative 30-million-order base at $15 each — and I label it modeled, because the record is the mechanism, not a cancel count.

Number to land: 60 → 57 at 10:02; 48 = 48 across the posting; $450K modeled · **Pivot to NACF:** A customer promise date is the same contract — I would decrement availability at the earliest physical signal, never at the accounting one. · **Do NOT say:** that cancels fell by a measured amount; "$2.5M" anywhere in this story.

OWNERSHIP · AIQB Q5 **Q3. "Describe a time when you had to transition a project you owned to a new owner. What steps did you take to make sure the transition went smoothly?"**

The thing I was transitioning was not the matcher — it was the exception report, and the new owner was Inventory Accounting. Before go-live I wrote what the unmatched-aging report had to prove — every S/4 aggregate posting matched to its header and lines, or aged with a cause: late line, header mistaken for lines, return without its original — at what grain, with what tolerance: 24 hours to a flag, 48 to a Sev. Their UAT entrance was that every case ties to the cent, so they had already run the arithmetic themselves. At cutover the opening SNB was seeded from the unposted ship confirms and the exit bar was "aging report empty or explained at T+1." In hypercare I read it with them every morning until they read it without me; the last step was month-end, where Financial On-Hand tied to MB5L through the ISM number rather than a bridge spreadsheet. I do not have a canonical days-to-tie figure and will not invent one; the handoff test was that nobody called me.

Number to land: > 24 h flag, > 48 h Sev; aging report empty or explained at T+1 · **Pivot to NACF:** I would hand every inventory exception report at an FC to a named owner with a tolerance before launch. · **Do NOT say:** a days-to-tie number; that I still run the report.

DIVE DEEP · AIQB Q6 **Q4. "Have you ever created a metric that helped identify a need for a change in your department? What was the metric? Why did you create it?"**

The metric was match rate — aggregate postings matched to their lines within 24 hours, divided by postings received — with SNB aging p95 beside it. I created it because the old world had no number for "how much of today's sales does S/4 not yet know about, and how much of that will never reconcile." The design target was 99.5% within 24 hours; at two thousand postings a day that is at most ten unmatched, each one on an aging report with a cause. The metric did two things. It made the failure direction visible — an unmatched posting keeps SNB high and under-states the promise, so the cost of a bad match rate is Replenishment over-ordering, not a customer cancel — and it told us where the breaks were: late POS lines, a header-level feed mistaken for lines, returns without originals. I would not present 99.5% as a result; it is the target that gave Inventory Accounting something to own.

Number to land: ≥ 99.5% within 24 h (design target); ≤ 10 unmatched/day at 2,000 postings · **Pivot to NACF:** I would want the same metric between receive confirmations and inventory postings at an FC: matched within a window, aged with a cause. · **Do NOT say:** that 99.5% was achieved; that the posting volume is record.

SAME STORY, THREE ANGLES — DATA · CONFLICT/INFLUENCE/BACKBONE · FAILURE-LEARNING NEW

DATA ANGLE · DIVE DEEP

"Twelve units, five lines, three hundred dollars — to the cent, and the drift is zero."

Headline metric: 75 + 50 + 100 + 25 + 50 = 300.00; drift 48 − 48 = 0

Grain SKU × node × sales line rolled to Aggregation#; the park rule and the last-line rule are the two pieces of logic. Honest limit: no canonical drift dollar exists.

CONFLICT / INFLUENCE ANGLE · EARN TRUST

"Finance kept its own reconciliation until the real report was theirs."

Headline metric: FOH truths 2 → 1

The influence move was showing the same on-hand from the physical side first and making the aging report Finance's, with its UAT entrance "ties to the cent." Cost ownership stayed with S/4 — a concession that bought the signature.

FAILURE / LEARNING ANGLE · ARE RIGHT, A LOT

"Under-stating is safe — and it is also invisible."

Headline metric: −2 never +2; but −10 on a parked posting is Replenishment's problem

The safe failure direction means a bad match rate shows up as over-ordering, not an alarm. Do differently: wire the aging report into Replenishment's exception view from day one, not just Finance's.

confirm whether Replenishment read the aging repo

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS, WITH NUMERIC ANSWERS NEW

Definitional — why isn't SNB in on-hand? Or is it?

It is inside Finance's book and outside the promise. Until the posting, S/4 Available still holds the 12 sold units, so any on-hand built from Available carries them; SNB is its own column — 60 and 12 — so Finance sees what tonight's posting removes. AFS subtracts it: 60 − 12 = 48. After the match both fall together: 48 and 0. The two canon phrasings of FOH differ on whether SNB is "added"; the arithmetic that cannot be wrong is that the sold unit is counted once.

Say: *"SNB is the reconciling column between Finance's book and the promise — in the row Finance reads, out of the number dotcom reads, and never counted twice."* **Verify #2**

Definitional — what if S/4 and ISM disagree at T+1 on a store?

At a store the only sold-not-posted bucket is SNB, so a T+1 difference is a posting that did not match or a line that did not arrive. Example: S/4 posted 12, ISM matched 10 → SNB 2, ISM Available 48 = MB52 48 (Test A passes) but the aging report shows the 2-unit line at 24 hours — that is the control, not the drift check. If Test A itself breaks, it is a posting after the watermark or a duplicate — timing or defect, re-cut or replay, never an edit to the book.

Say: *"At a store, T+1 disagreement lives on the aging report, and it is a Sev at 48 hours with a cause, never a plug."*

Who owns the publish of Financial On-Hand — ISM or S/4?

ISM publishes FOH because it holds the sold-not-posted units S/4 will only see at the aggregate; S/4 owns the posted book, the settlement authority and cost. It is one truth because the two are forced to agree — SNB decrements only on a matched posting, Σ FOH ties to MB5L before Finance closes, tolerance zero in units, and any value gap is a WAC question for S/4.

Say: *"ISM publishes it; S/4 owns the book and the cost; the month-end tie is what makes it one number."*

20-SECOND VERSION + NACF BRIDGE NEW

20-second version. S/4 posts store sales as a nightly aggregate, so I gave sold-but-not-posted units their own bucket, Shipped-Not-Billed — up at the ring, down only on a matched posting — de-aggregated the posting's cost back to each line to the cent, and published one Financial On-Hand that Finance and Operations both read and that ties to MB5L. Two truths became one; the failure direction is under-sell, never over-sell; about $0.6M a year, modeled.

NACF bridge. NACF's equivalent is the gap between a physical event and its inventory posting — a receive confirmation, a transfer, a vendor return — and whether placement and Finance read one on-hand or two. I would put the same three rules in: decrement at the physical signal, clear only on a matched posting, and an aging report with a named owner and a 24/48-hour clock.

Safe-say box. "A unit sold at 10:02 is off the promise at 10:02, not at the nightly posting — and if the posting will not match we under-sell, never over-sell." · "Two Financial On-Hand truths became one; the dollar view is about $0.6M a year, modeled — the record carries no drift dollar."

VERIFY BEFORE YOU SAY IT — terms that stayed ambiguous, each with the safe sentence NEW

Last-resort list: items absent from every source in /tmp/sources and the master, or where two canon passages disagree. Confirm with your own memory before the loop; if unsure, say the safe sentence.

#	ITEM	WHERE USED	STATUS	SAFE SENTENCE IF UNSURE
1	**"FOH" expansion. Every source says *Financial On-Hand*. The brief's phrase "on-hand free of holds" appears nowhere in /tmp/sources or the master.**	Cram sheet, card, S1-R, S3-R	absent from sources	"In my program FOH meant Financial On-Hand — Finance's number: Available plus merchandise reserve plus lost-and-found. If your FOH means free-on-hand — unrestricted stock free of holds — that is what we called Available, S/4's unrestricted book."
2	**Does FOH include SNB? S1 formula: FOH = Avail + MerchRes + LostFound. S3 walkthrough: "… plus lost-and-found plus SNB." Until the posting, S/4 Available still contains sold units, so adding SNB would count them twice unless "available" there means the posted book less SNB.**	Card, S1-R W2 row 8, S3-R trap 1	CONFLICT inside canon	"Financial On-Hand is Available plus merchandise reserve plus lost-and-found, with Shipped-Not-Billed carried as its own reconciling column so the sold unit is counted once and Finance sees what tonight's posting removes; it ties to MB5L at month-end."
3	**Where a web-order commit lands: GFiber mapping row says "Commit → Picking Reserve"; R4 (record) says Σ open STO = PickRes and Σ open orders = EcomPick. This packet follows R4 (web commit → EcomPick; STO → PickRes).**	Card, S1-R W1 E3/E4	CONFLICT inside canon	"A store transfer enters Picking Reserve when the STO is created; a web order enters the ecom buckets when it is committed — and the tie-out is Σ open STO = Picking Reserve, Σ open orders = Ecom Pick, tolerance zero."
4	**Ecom Pack at a DC: R3 says "a Pack balance at a DC must be 0 by definition"; the canon walk carries Ecom Pack 60 at the DC. This packet keeps the canon figure and treats Pack as the packed-not-ship-confirmed window.**	Card, S1-R W1	CONFLICT inside canon	"Ecom Pack is the packed-not-yet-shipped window; at a DC it clears on ship confirm, so its end-of-day balance should be zero."
5	**The reading "WMS 980 = 940 physically pickable + 40 shipped-not-posted" (R6 "shipped-not-posted netted via SNB") is this packet's interpretation to keep the ship-confirm step consistent; the canon example does not spell it out.**	S1-R setup, E6–E7, trap 1 of S1-R-infra	interpretation	"For the out-of-balance comparison the floor count is netted for units that have shipped but not yet posted, so a ship confirm never manufactures a phantom OOB."
6	**FSD dates 3/5/25 → 5/16/25 → 6/5/25 and the three signing-org names (Supply Chain Strategy, Inventory Management, FSC Inventory Accounting) — GFiber v8 only.**	S1-R, S3-R phases	UNSUPPORTED-anchor	"Signed in the first week of June 2025; three orgs signed."
7	**$1M MCS support retired — Adobe-prep playbook and GFiber only.**	S1-R results	UNSUPPORTED-anchor	"About a million a year of legacy support cost retired — my program number."
8	**Cutover-night clock times (20:00 → 01:00 → 06:00) and the 1,000 events/hour trigger volume.**	S1-R-infra Table 2	illustrative	"The order of steps is record; I would not quote the hours."
9	**Whether Replenishment read the unmatched-aging report (failure-learning angle in S3-R).**	S3-R angle card	not in record	"What I would do differently is wire the aging report into Replenishment's exception view — I don't have a record that we did."
10	**Whether a cause class was recorded on every AFS Correction audit row (carried from Packet 3 U6).**	S1-R trap 2	not in record	"Every correction had a screen, a role and an audit row; the cause class is what I would make mandatory on the row."
11	**Days-to-tie at month-end (FOH → MB5L).**	S3-R	not in record	"The mechanism is canonical; I don't have a days-to-tie figure and won't invent one."
12	**Physical-to-S/4 posting latency for an RF scan in seconds (not in any source; only the ≤15-min WMS feed and <60-s republish budgets are).**	S1-R-infra	absent from sources	"The budgets I owned were the fifteen-minute floor feed and the sixty-second republish; the scan-to-WMS hop was the WMS team's and I did not set a number on it."

Never say (this add-on). "free on hand" as the program's term · a bare "$2.5M" or "$1.5M" without its noun · "100 of 400 devices" or any cost multiplier · "the ISM issues log" (the 836-row log is UDC's) · "99.5% match rate" as a result · "fifteen tracks" · "20+ systems" · any BOM / component framing · the unit counts of the walk as program data.

INTERVIEW-PREP PACKET 4 · PER-INTERVIEWER · PROCESS-IMPROVEMENT STAR EDITION

Amazon NACF Supply Chain loop — Packet 4: James Cabreros

Amazon — Senior Supply Chain Manager, NACF Supply Chain (L6)

James Cabreros (11:00 slot; schedule listed Zhaowen Lan)

Senior Manager, Supply Chain — placement / configuration architecture, North America Customer Fulfillment

Friday, October 30, 2026 · 11:00 am PDT

COMPANION TO THE EXISTING LAN PACKET (AMAZON-NACF-PANEL-4-LAN-KIMI-K3), WHICH IS UNCHANGED. THIS PACKET STANDS ALONE.

> **Strategy in one line.** He migrates a legacy placement rules engine to a centralized policy platform and governs hundreds of configuration changes a week. Give him process improvements told as STAR: the defect I found, the flow I mapped, the control I set, the SOP I wrote, how I validated before deploying, and how I closed the loop after an incident. Each one carries a priced trade-off and a failure line. Open with J5 (change governance) or J1 (one governed dial), keep J8 (the UAT that crashed) ready for the failure question, and use J4 (the Google Fiber end-to-end flow) when he asks about new node types, escape routing or connectivity.

Already told on Thu Oct 29 (to Snigdha Tripathy and Ryan Hoerger): S/4HANA / ISM, Flexport estimation (FF App), Shipment Visibility, safety stock, the 200-lane lead-time program. None of these is a primary here. Each appears only as a one-line bench bridge.

Honesty rules on every page: J1–J3 (Walmart pre-purchase delivery) and J4 / J7 (Google Fiber E-series) are **DESIGN CASES** from my own interview prep. Say “I designed / in the model / here is how I would run it,” never “delivered.” J5, J6 and J8 are **RECORD**. Every number carries a basis label: record · record-from-docs · user anchor · modeled · illustrative.

Canon: amazon/amazon-l6-scm-master-packet.html (S4, S13, S14, S15, S19–S21, E1–E12, §3.0); Apple PM III workbook v11 (F4, G1, G2, M1, D1–D3, I1); /tmp/sources/NUMBERS-RECON.md (CANON v2); resume (Rajesh_ChandrasekaranApple); ROMA “S!ONE NORAM Testing Strategy Review” (Feb 2026); GFiber MASTER Packet v8 (Part 3 design prompts, Stage 10 release workflow). His profile text: supplied by the user (LinkedIn not fetched).

1. Cram sheet — read this, then walk in

Profile hooks (from the profile text the user supplied; nothing else asserted). (1) Migrating a **legacy placement rules engine to a centralized policy platform**: architecture, alignment, sequencing, training. (2) **AI-assisted configuration tooling** so non-specialists can self-serve network changes. (3) **New node types**: inbound/outbound connectivity, crossdock, **escape routing**, **capacity signaling**. (4) **Configuration governance**: pre-deployment validation, change-management SOPs, post-incident corrective actions, fewer unintended deployments, auditability across hundreds of weekly changes. (5) **Placement-architecture POC** across building types with Transportation, Finance, Network Topology and Operations. **What he is listening for:** can I turn a rule into a governed instrument, validate a change before it deploys, and leave a control behind after an incident?

#	STORY (ORDER TO TELL)	BASIS	THE ONE NUMBER IT LANDS
J5	Change governance: a rule change rides the train or doesn't ship; the QA lead owns the gate	RECORD (+E8 design)	**20-person team, 6-week → 4-week cadence in 6 weeks; critical defects per release −50% (record)**
J1	Walmart: flat promise buffer → one governed dial, b = 1.645σ	DESIGN CASE	**fast-promise share 7.6% → 39.6% at the same 95% floor, in the model**
J6	Manhattan: allocation for 3 DCs + 100 stores; Cyber Monday post-mortem; $2.5M discrepancy control	RECORD / user anchor	**99% fill vs 95% goal; stockouts −20%; 4 standing mechanisms; ~200 orders / $2.5M of order value → 0**
J7	Legacy cutover: tolerance first, three mocks, one promise publisher	DESIGN on RECORD	**mocks 7.0% → 1.8% → 0.3% vs a 0.5% tolerance published before mock 1 (record)**
J4	Google Fiber end-to-end flow: PO → EDI → 3PL → van → install → return	DESIGN CASE	**5 control points, 1 ledger; e.g. returns dispositioned ≤14 days ≥95% (design target)**
J2	Walmart WBR + Andon: 7 outputs over 10 inputs, a 24-hour control loop	DESIGN CASE	**detection-to-action ~30 days → <24 h by design; 0.97 × 0.985 × 0.996 ≈ 95.2%**
J3	Walmart managed-shipping funnel: an insurance contract + a shadow gate	DESIGN CASE	**≈$3.7M/yr per +10 pts of enrolled GMV, modeled**
J8	FAILURE: UAT crashed on concurrent logins (G1); my in-transit rule starved dotcom (S4)	RECORD	**5 users × 10 scenarios passed; crashed 2 days before sign-off → numeric load criteria ever since**

Three sentences to open with.

1. "My process work has one habit: I turn a rule someone tunes by hand into a governed instrument with an owner, a validation gate before it deploys, and a corrective action after it fails."
2. "A change rides the release train or it doesn't ship, and the regression matrix at the true grain is the gate. That's how I'd think about hundreds of weekly placement changes."
3. "I'll tell you which of my numbers are record and which are design-case models. The Walmart and Google Fiber pieces are designs I built; Manhattan, Sephora and Elementum are delivered."

Five numbers never to get wrong.

1. Mocks **7.0%** → **1.8%** → **0.3%** against a **0.5%** tolerance published with Finance **before** mock 1 (record, Apple D2).
2. Critical defects per release **−50%**; **20-person** team; **6-week** → **4-week** in **6 weeks** (record, resume + Apple D3).
3. Manhattan: **3 DCs + 100 stores**, **99% fill vs 95%** goal, about **$6M on the line** and about **$8M of the day's sales protected**; stockouts **−20%** (record).
4. Walmart design case: **7.6%** → **39.6%** fast-promise share at a held **95%** floor, always "in the model." Never a delivered dollar.
5. G1: **5 users × 10 scenarios** passed; concurrent logins crashed it **2 days** before sign-off. Since then, every gate has a load line, e.g. Flexport **500 containers in 20 min at 99.6%** (record-from-docs).

2. His bullets → my stories

Left column: his profile bullet, as supplied. Right: the story that answers it, and the sentence that bridges it. If he asks a bullet directly, open with the bridge sentence, then go to the STAR.

HIS BULLET	PRIMARY / BACKUP	BRIDGE SENTENCE (SAY THIS FIRST)
Legacy placement rules engine → centralized policy platform (architecture, alignment, sequencing, training)	J7 (cutover) · J1 (rule → one dial) · J8-B (rule fixed through the signed policy)	“A rules migration fails the way a WMS cutover fails: two publishers at once. I publish a tolerance before mock 1, read mocks by cause, and switch consumers to one publisher at a time. Zero the old one first, then publish the new one.”
… **training delivery**	J5 (S15 user guide; QA owns the gate) · J7 (device readiness moved into training entrance criteria, G2)	“Training is a gate, not an event. Proven devices and a user guide the skeptic wrote, both before the date.”
AI-assisted configuration tooling so non-specialists self-serve	J3 (shadow-run before flip) · J1 (a dial a business owner reads on Monday) · bench I1 (LLM triage agent)	“Self-serve is safe when the tool shows the operator the outcome before the flip. In my design, every seller enrolment is shadow-run on its own history first. In the agent I built, the rule was no citation, no proposal.”
New node types: inbound/outbound connectivity, crossdock, **escape routing**, **capacity signaling**	J4 (van as a node; EDI inbound; returns exits) · J6-A (rebalance so no DC drowns) · J2 (Andon as a capacity signal)	“When I add a node type, it gets four things before it gets volume: a legal inbound flow, a legal outbound flow, a named escape route for every unit that leaves the happy path, and a capacity signal that throttles it automatically.”
Configuration governance: pre-deployment validation, change-management SOPs	J5 (release train) · J7 (three mocks) · J8-A (numeric UAT entrance criteria)	“A change rides the train or doesn’t ship; the regression matrix at the true grain is the gate; go/no-go reads counted rows, not confidence.”
… **post-incident corrective actions**; fewer unintended deployments	J6-A (heartbeat, DST checklist, 3σ page rule, rehearsed playbook) · J6-B (standing reconciliation) · J8-B (four regression cells)	“Every incident has to leave at least one mechanism behind, not a reminder. After Cyber Monday we shipped four, and the next peak ran boring.”
… **auditability across hundreds of weekly changes**	J5 (manifest + transport log) · J4 (append-only serial ledger) · J6-B (per-line before/after)	“Every change has one document, one owner and a reversal that references the original. No manual table edits, ever.”
Placement-architecture POC across building types with Transportation, Finance, Network Topology, Ops	J1 (four policies on one table; breach priced) · J7 (tolerance signed with Finance) · J4 (direct/indirect boundary table)	“Partners argue less when the options sit on one table with a price per row. Finance signs the tolerance or the breach cost before anyone tunes anything.”

> **If he asks “what would you do in your first 90 days here?”** Map the change flow end to end (who requests, who validates, who deploys, who can roll back). Count unintended deployments by cause class for the last quarter. Pick the top cause and put a gate on it. Then write it down as an SOP the operators own, not me. That is J5’s method applied to his world.

3. Trade-off ledger — every story, one row

Decision | options | chosen | rejected and why | what it cost | the metric that judged it. Design-case rows are marked (D); every number keeps its basis label.

STORY	DECISION	OPTIONS	CHOSEN	REJECTED & WHY	WHAT IT COST	METRIC
J1 (D)	How to set the promise buffer	Uniform 1.10 d · σ-proportional dial · min-days · profit-optimal · per-lane ML	One governed dial, b = 1.645σ	Per-lane learned buffers: more value on paper, but invisible governance. Profit-optimal: handed to Finance, not adopted by default.	Widest lanes got slower promises: buffer 1.10 → 2.63 d (model)	Fast share 7.6% → 39.6% at a 95% floor (model)
J2 (D)	How many metrics on the WBR	Every team's dashboard · 7 outputs over 10 inputs	7 over 10, each with an owner	"More metrics": a metric nobody owns is noise; two dashboards is zero dashboards	Teams lost favorite metrics; sellers kept the slower, fair 30-day window	Detection-to-action ~30 d → <24 h (design)
J3 (D)	How to restart stalled enrolment	Market harder · hard cliff on label purchase · tiered insurance contract	All-or-nothing bundle, protection tiered by depth	Banners and emails: the stall was an unpriced trade. A hard cliff reads as a tax to sellers with negotiated rates.	Enforcement deferred; slower adoption curve accepted	Activations/week + 30-day retention; ≈$3.7M/yr per +10 pts (modeled)
J4 (D)	Gate van replenishment	Replenish on request · count-as-gate	No new issue without a posted weekly count	Replenish-on-request: hides the unmeasured stock	Slower issues in week one	Unaccounted units/contractor/month → near 0
J4 (D)	Untested returns	Grade on the truck · central test bench	No test, no grade, no availability	Truck grading: fast but inconsistent; one bad unit = a truck roll	A hop and some days; refurb stock lags in a surge	Dispositioned ≤14 d ≥95%; warranty recovery ≥80%
J5	Cadence vs quality	Keep 6-week · 4-week with a QA gate · continuous	4-week, QA-authored definition-of-done, drop date with reason codes	Hotfixes / "just this once" outside the train: untraceable	Low-impact stories dropped visibly; I covered some	Critical defects/release −50% (record)
J6-A	Clear the Cyber Monday backlog	FIFO · wait for root cause · promise-at-risk first	Promise-at-risk, reversible, logged	FIFO clears cheap orders while at-risk promises age; waiting had an hourly price	Some early cheap orders waited; manual, throwaway work	99% fill vs 95% goal (record)
J6-B	Fix a $2.5M OMS↔WMS gap	Quiet cross-table script · tell the customer first	Transparency + per-line reversible patch	A two-day script can't be verified; an audit finding becomes a reputation issue	My time in a war room; risk of being wrong in front of the customer	~200 orders → 0; standing daily report (user anchor)
J7	Define "good enough" for cutover	Negotiate at go-live · publish tolerance before mock 1	0.5% with Finance before mock 1	Negotiating at go-live turns arithmetic into politics	Three mocks cost weeks; 72-h freeze delayed receipts	7.0 → 1.8 → 0.3% (record)
J8-A	UAT exit criteria	Scenario pass only · scenario + numeric load	Numeric entrance/exit incl. concurrency (after the miss)	"Works for us" as evidence: it was why I failed	Lost sign-off date; customer confidence spent	Load line on every gate since (record)
J8-B	Fixing my own rule	Hotfix / side config · signed FSD change on cadence	Signed change, back-tested, on the monthly train	Hotfix makes the fix as untraceable as the error	Slower than a hotfix; lanes below the floor stayed out	Oversell increase 0; kill switch never fired (user anchor)

> **THE PATTERN HE SHOULD HEAR**
>
> I rarely pick the fastest option. I pick the one that stays **governable**: one owner, one document, one number decided in advance, and a cheap rollback. Then I say out loud what it cost.

4. Process-improvement toolkit — how I actually do it (each step proven in a story)

STEP	WHAT I DO	WHERE I DID IT (BASIS)
1. Find the process defect	Look for the **contradiction**, not the complaint: inventory present but backorders rising; accuracy "green" but the tail failing; tests pass but users can't finish a flow. Then ask whether it's a **policy defect or a data defect**.	J6-A: ATP > 0 with backorders rising was my entry bar to declare an incident (record). J8-B: the lanes were on time, my rule forbade promising them, so it was a policy defect (user anchor). J1: 95.8% portfolio accuracy hid z = 5.0 on one cohort and 0.69 on another (model).
2. Map the flow	**Stocks and flows**: every bucket a unit can sit in, every flow between them, one document per flow, one owner per number. If a flow has no document, add the document before adding a report.	J4: PO → 855 → ASN → 3PL → van → install → return, each hop with its own document (design). J2: seven outputs decomposed into ten owned inputs (design).
3. Set the control	A **number decided before the event**: a tolerance, a gate, a tripwire, plus a **kill switch** that fails in the safe direction.	J7: 0.5% tolerance published with Finance before mock 1 (record). J8-B: per-lane window plus the Aging In-Transit kill switch (user anchor). J2: Andon at 2× baseline, n ≥ 30, act <24 h (design).
4. Write the SOP	Let the **skeptic author the gate**, keep it short, publish it in the tool people already use, and put the owner's name on it, not mine.	J5: the QA lead wrote the definition-of-done; Jira review-status fields; a user guide that neighbouring teams copied (record). J6-A: the rebalance playbook written down and rehearsed (record).
5. Validate before deploying	**Back-test on history, shadow-run on live inputs, rehearse with full data.** Read results by cause class, never by headline. Test at the customer's shape (load, concurrency).	J8-B: back-test against receiving history, the step v1 skipped. J1/J3: four shadow weeks / per-seller shadow run (design). J7: three mocks on full production data (record). J8-A: concurrency in entrance criteria (record).
6. Close the loop after an incident	**Blameless post-mortem from the log timeline**, at least one mechanism per incident, an owner per action, and a **standing report** that makes recurrence visible.	J6-A: heartbeat, DST checklist, 3σ page rule, rehearsed playbook; next peak ran boring (record). J6-B: reason-coded OMS↔WMS reconciliation read before every exec review (user anchor). J8-B: four regression cells added (user anchor).

LIGHT MATH THAT CARRIES THE PROCESS POINT (J5, MODELED FROM THE CADENCE)

Releases per year go 52 ÷ 6 ≈ 8.7 → 52 ÷ 4 = 13 (+50%). If critical defects *per release* fall 50%, then escaped criticals per year go 8.7c → 13 × 0.5c = 6.5c, about **−25% in absolute escapes even while shipping 50% more often**. A faster change cadence is safe only if the gate improves faster than the cadence does. The −50% is record; the per-year figure is my arithmetic on the cadence, with c being whatever the baseline count was.

For his "hundreds of weekly changes": the same six steps scale only if steps 3–5 are automated per change class (validation is a test, not a meeting) and step 6 writes a new test whenever something escapes. That is how I'd expect "fewer unintended deployments" to be engineered.

J1 — Walmart pre-purchase delivery: the flat promise buffer rebuilt as one governed dial

DESIGN CASE: built from my own interview prep for a Walmart Marketplace pre-purchase delivery-experience role (war book + solver model, illustrative data). Not a delivered result. Say "I designed" and "in the model." **Lived record paired with it:** Apple F4, the Elementum 200-lane lead-time distributions (already told to Snigdha/Ryan, so one line only).

His bullet it answers: legacy rules → a centralized policy instrument; placement POC with Finance and Transportation; AI/self-serve tooling a business owner can read.

Dive Deep: the portfolio number (95.8%) was green; the per-cohort z-scores (5.0 vs 0.69) showed over- and under-insurance at the same time.

Invent and Simplify: a hundred hand-tuned buffers became one published dial, b = k·σ, owned by a business owner.

Insist on the Highest Standards: shadow mode with a promotion bar written before week one; a Q4 re-solve rule so peak can't silently break the floor.

Earn Trust: the cost (slower promises on the widest lanes) put on the table as a priced row, not hidden.

60-SECOND PITCH

"**Situation.** In a design case I built for a marketplace delivery-promise role, the promised date was order time plus seller handling plus predicted transit plus a buffer, and the buffer was a flat 1.10 days on every lane. In my model of twelve lane cohorts, about a million orders a week, it printed 95.8% accuracy but only 7.6% of orders got a fast promise. **Task.** Turn a hand-tuned rule into a governed policy without breaking the 95% accuracy floor. **Action.** I decomposed accuracy into seller × carrier × Φ(buffer/σ), showed the flat buffer was 5.0 standard deviations on the tightest cohort and 0.69 on the widest, put four policies on one priced table, and recommended one dial, b = 1.645σ, validated in four shadow weeks before any customer saw a date. **Result.** In the model, fast-promise share goes 7.6% to 39.6% at exactly 95%, and the average promise drops from 3.09 to 2.75 days. The dial is printed in the weekly review header, with a named owner. The lived version of this is my Elementum lead-time work: 200 lanes, promise at the tail, 99% accuracy."

S — A marketplace promises delivery on inventory it never touches: seller picks, a partially controlled carrier carries, and the customer blames the marketplace. Promised date = order time + configured handling + predicted transit + buffer. The incumbent buffer was **uniform, about 1.10 days**, set once and owned by nobody between reviews. Model scale: **12 lane cohorts, ~1M orders/week, σ from 0.22 to 1.60 days** (illustrative). Baselines in the model: accuracy **95.8%** vs a 95% floor, average promised day **3.09**, fast-promise share (≤2 days) **7.6%**, weekly modeled profit **$5.69M**. The real baseline: **no governed owner** of the speed-vs-accuracy trade.

T — My role in the case was promise-policy lead: decompose where the buffer was wasted and where it was thin, put priced alternatives on one table, design the validation gates, and leave a governance instrument, not a tuning habit. The constraint: hold 95% accuracy on every cohort. The model's stated economics: a breach costs about **$12** against about **$6.50** of contribution margin (model assumptions, not a measured P&L).

A — Five gated phases, as I designed them:

- **Discovery: find the defect.** Wrote the accuracy factorization (P(seller ships in window) × P(carrier meets transit) × Φ(b/σ)) and the buffer-waste audit. The indictment in two lines: 1.10 ÷ 0.22 = **z 5.0** (Φ ≈ 99.99997%) on the tightest cohort; 1.10 ÷ 1.60 = **z 0.69** (Φ ≈ 75.4%) on the widest. *Exit:* the question changes from "how much buffer" to "where should it sit."
- **Plan & Design: options on one table.** A uniform (incumbent) · B σ-proportional, one dial k · C minimum-days at the floor · D profit-optimal on the priced breach. Gates designed up front: shadow mode, a promotion bar, a warm rollback. *Exit:* the dial k named as a published policy instrument with an owner.
- **Build & Test: validate before deploying.** Φ(1.645) = 0.95 holds the floor on every cohort by construction; the Q4 drill (σ × ~1.45) shows a frozen summer dial printing **91.9%**, below the floor, so a re-solve rule is written. *Exit:* every policy reproducible independently by the engineering/data-science owners.

- **Cutover: shadow, then promote.** Challenger computed and logged per order for **four consecutive weeks**, never displayed; promote only if would-be accuracy holds the floor on logged live orders with no rise in contact signals. Rollback = one flag back to the incumbent. *Exit:* promotion bar published before shadow week 1.
- **Hypercare: close the loop.** k printed in the Monday review header; p90 error and buffer exceedance next to the mean; k re-solved per regime (October for peak). *Exit:* a business owner, not data science, owns the dial.

Mine vs theirs (in the case): mine were the factorization, the waste audit, the four-policy table, the proofs and the gates. The engine, the transit models and σ estimates belong to engineering and data science; the breach price belongs to Finance.

R — What the design produces, all **in the model**:

- **%** Fast-promise share **7.6%** → **39.6%** (+32 pts) at a held **95.0%** floor (modeled, recomputed from the solver model).
- **Time** Average promised day **3.09** → **2.75**; tightest cohort's buffer 1.10 → 0.36 d; widest 1.10 → 2.63 d, longer on purpose (model).
- **$** +$255K/week vs uniform, ≈ **$13.3M/yr** annualized (modeled ×52). Policy D (97.8% accuracy, ≈ +$20M/yr) handed to Finance as a governance choice, never merged with the $13.3M.
- **Process** One dial, one owner, one shadow gate, one regime rule, instead of tuning by whoever touched the last model.
- **Lived record behind it (Apple F4):** 200 lanes, measured distributions, promise at the tail, **99% lead-time accuracy**, **580,000 units** and about **$1.5M of carrying cost released** (record).

TRADE-OFF I MADE

Options: per-lane ML-learned buffers (data science's preference) vs one governed dial. **Chose:** the dial first. **Rejected:** learned buffers, because they add value on paper but governance is invisible, and nobody can audit a hundred micro-decisions on a Monday. **Cost:** the widest lanes got honestly slower promises (2.63-day buffer in the model), and the last increment of profit (policy D) was left as a Finance decision. **Metric:** fast share at the held floor.

Failure / learning. From the lived F4 record: I shipped the lane distributions before the drift flag, and a lane quietly degraded until a planner caught it by hand. In this design, the regime re-solve and the tail metrics ship *with* the dial, not after.

SAFE-SAY (most attackable number): "Seven-point-six to thirty-nine-point-six percent is in my model, a twelve-cohort illustrative book. It's a design case, not a delivered result."

"What's your source?" "My own solver model for a Walmart delivery-promise role, recomputed. The delivered version of this muscle is Elementum: two hundred lanes, ninety-nine percent lead-time accuracy."

20-SECOND VERSION

"A flat 1.10-day buffer was over-insuring metro lanes at five sigma and under-insuring rural lanes at 0.69. I designed one governed dial, b = 1.645σ, validated in shadow weeks. In the model, fast promises went 7.6 to 39.6 percent at the same 95% floor, and a business owner now reads the dial every Monday."

Probing Q&A

Q1. Why not let ML learn per-lane buffers? Isn't that more accurate?

Possibly more profit on paper, but it's ungovernable: a hundred micro-decisions no business owner can audit. The dial captures most of the value, and when σ estimates improve, that flows into speed visibly. I put the ML option on the table as a priced row, so the no was a decision, not an opinion. For a placement rules platform I'd apply the same rule: a parameter a human owns beats a policy nobody can read.

Q2. How do you validate a policy change before customers see it?

Shadow mode: the challenger is computed and logged per order for four weeks, never displayed. It’s promoted only if would-be accuracy holds the floor on logged live orders with no rise in contacts. The bar is published before shadow week one, and rollback is one flag.

Q3. What breaks this at peak?

Variance regime change. In the model, σ × ~1.45 drops a frozen summer dial to 91.9%. So k is re-solved per regime and published in October. Never frozen through peak.

Q4. Did you deliver this?

No. It’s a design case I built for a marketplace delivery-promise role. What I delivered is the same idea at Elementum: measured lead-time distributions on 200 lanes, promise at the 99th percentile, 580,000 units and about $1.5M of carrying cost released.

J2 — Walmart pre-purchase delivery: the weekly business review and an Andon for promise yield (the operating mechanism)

DESIGN CASE: the WBR design from my Walmart-role prep (Tech Ops WBR deep dive, illustrative sample weeks). Not a delivered result. The WBR *format* (input levers under output metrics, ±5% relative week-over-week, Monday–Sunday week) is real: I copied it from the Flexport LSA WBR I ran (record; already told, so one line only).

His bullet it answers: configuration governance and post-incident corrective action at scale; capacity signaling; auditability (one owner, one definition per metric).

Ownership: an output metric owned by a committee is owned by nobody between Tuesdays; I put one name on the output block.

Insist on the Highest Standards: hard reds on policy floors regardless of trend; a red that arrives without cause, owner and date counts as a process miss.

Dive Deep: the factor math names the lever and the owner in minutes; mix-adjusted twins stop Simpson's paradox from flattering a quarter.

Bias for Action: the Andon acts within 24 hours at the seller-lane cell instead of waiting for a 30-day rolling window.

60-SECOND PITCH

"**Situation.** In a design case for a marketplace delivery team, the promise was owned by four teams: data science, engineering, seller ops and carrier programs. The scorecards ran on 30-day rolling windows, so a degrading seller or carrier did weeks of damage before anything fired, and a red week turned into a blame negotiation. **Task.** Design the weekly business review and a control loop faster than 30 days. **Action.** One glossary and audited denominators first. Then seven output metrics over ten input levers, each with an owner and a roll-up. The decomposition, accuracy ≈ seller × carrier × Φ(b/σ), answers 'which lever moved' in minutes. Reds are pre-wired before the room. And an Andon: a 7-day control chart per seller-lane cell that acts within 24 hours. **Result.** On the sample data, red-week attribution goes from days of negotiation to minutes; detection-to-action goes from about 30 days to under 24 hours by design; and one joint headline, Promise Yield, sits at a 41.5% sample baseline. The only dollar is modeled: about $580K per caught episode."

S — Three parties make the promise: the seller ships in a window, a carrier meets transit, a buffer absorbs the rest. Measurement was the problem, not effort. Metrics lived on **30-day rolling windows** that smear a step change into a drift; aggregates hid variance (worked example: a carrier at **97% nationally and 82% in the Southeast**); three teams kept three clocks (order, ship, promise date). Sample baseline: fast share **43.6%** × accuracy **95.2%** ≈ **41.5% Promise Yield** (docs' illustrative sample).

T — Design the WBR for pre-purchase delivery: outputs a customer feels, inputs a named owner can turn this week, the math that connects them, thresholds, and a control loop faster than the scorecard. Then hand it to owners.

A — Five gated phases, as designed:

- **Discovery: one glossary.** Every metric gets one definition, one owner, one grain, one date basis. Denominators audited (cancelled orders quietly leaving the OTD base). *Exit:* three clocks reconciled to one event source.
- **Plan & Design: the architecture.** Seven outputs (promise accuracy ≥95%, OTD ≥90% floor, late shipment ≤5%, cancellation ≤2%, fast-promise penetration, WISMO contacts, conversion lift) over ten inputs (managed-shipping share, handling adherence, carrier lane SLA, transit-model error, buffer calibration, feed accuracy, eligibility, engine latency, onboarding, retention). Red/green at **±5% relative WoW**; hard reds on floors. *Exit:* every output decomposes into named inputs with owners.
- **Build & Test: prove it on sample weeks.** 0.97 × 0.985 × 0.996 ≈ **95.2%**. Drill: drop the Southeast carrier cell to 82% on a tenth of volume; carrier factor 0.90 × 0.985 + 0.10 × 0.82 = 0.9685, so accuracy falls to ≈ **93.6%**, and the decomposition names carrier programs as the owner. *Exit:* the six-step loop (measure → variance → decompose → root-cause → act → verify) runs end to end.

- **Cutover: the rhythm.** Monday data freeze, Tuesday review, reds pre-wired with cause, owner and date. “The meeting decides; it never discovers.” *Exit:* two pre-wired cycles.
- **Hypercare: the control loop.** Mix-adjusted twins next to every raw output. Andon: **7-day EWMA/CUSUM per seller-lane cell**, tripwire at a sustained **2× baseline** breach rate with **n ≥ 30**, act **<24 h** (widen that cell’s buffer or pull its fast badge), auto-restore on recovery, false-trip bar **<5%**. *Exit:* the verify step. If an input moved and its output didn’t, the lever map is declared wrong, in writing.

R — What the design produces (sample data / modeled):

- **Time** Red-week attribution: days → minutes (sample drill); detection-to-action ~30 days → **<24 h** by design.
- # 7 outputs / 10 inputs / 1 joint headline / 1 action log, each with one owner.
- **%** Promise Yield **41.5%** sample baseline, four-quarter design target 50%.
- **$** ≈ **$0.58M per caught episode**, modeled: ≈$192K/week of excess breaches × 3 weeks saved ($12 breach cost is the model’s assumption). Not annualized; I don’t know the episode frequency, so I don’t invent one.

TRADE-OFF I MADE

Options: act on the 30-day seller scorecard (fair to sellers, slow for customers) vs act on a 7-day cell signal (fast, but noisier). **Chose both, split by consequence:** the Andon acts on *cells and badges* within 24 hours; seller *scorecards* stay on the fair 30-day window. **Rejected:** punishing sellers on 7-day noise. **Cost:** a false-trip budget (<5%) and an auto-restore rule to maintain. **Metric:** detection-to-action time.

Failure / learning. The program wanted more metrics; my first draft had more than seven. I learned (and wrote into the design) that a metric nobody owns or acts on comes off the board, and that two dashboards means nobody watches either.

SAFE-SAY: “Ninety-five-point-two is the docs’ illustrative sample week, and the 30-days-to-24-hours is by design. I never claim a production metric moved.”
“Source?” “My Walmart-role WBR deep dive, built on the Flexport LSA WBR format I actually ran.”

20-SECOND VERSION

“A delivery promise owned by four teams and measured on 30-day windows. I designed a WBR with seven outputs over ten owned inputs, a factor decomposition that names the lever in minutes, and an Andon per seller-lane cell that acts in under 24 hours, while seller scorecards stay on the fair 30-day clock.”

Probing Q&A

Q1. How is this a capacity signal for a network?

The Andon is a throttle at the grain where variance lives. A cell breaching at 2× baseline gets its fast badge pulled or its buffer widened automatically, so a degrading node or lane stops taking promises it can’t keep. For a new node type I’d wire the same: a sustained signal, a minimum sample, an automatic action, and an auto-restore.

Q2. How do you stop the WBR from becoming a viewing?

Pre-wire rule: reds arrive with cause, owner and date or they count as a process miss. The meeting decides; it never discovers.

Q3. What’s the verify step for?

To falsify the lever map itself. If an input moved and its output didn’t, the roll-up hypothesis is wrong, and that gets written down. That’s what keeps the instrument honest after I leave.

Q4. Have you run a WBR for real?

Yes, at Flexport; you may have heard about it yesterday. This design is where I carried the decomposition math and the control loop furthest, as a design case.

J3 — Walmart: the stalled managed-shipping program, redesigned as an enrolment process with a shadow gate

DESIGN CASE: from my Walmart-role prep (war book, case materials). Baselines are "in my case materials." I claim a design, never an adoption curve or a delivered dollar.

His bullet it answers: self-serve configuration for non-specialists (sellers flipping their own settings) with guardrails; change-management SOPs; training/enablement at scale.

Think Big: stopped marketing a settings toggle; redesigned the offer as an insurance contract that thousands of sellers can self-select into.

Customer Obsession: observed handling replaces declared handling at the source, so the customer's promise stops depending on a seller's optimism.

Insist on the Highest Standards: shadow-verify every seller's settings on their own history before the flip; waves board only on published criteria.

Earn Trust: a kill condition is written before launch: one broken protection promise stops enrolment.

60-SECOND PITCH

"**Situation.** In a design case for a marketplace, the managed-shipping program, where the marketplace picks transit settings and absorbs carrier-delay accountability, had stalled at roughly 38 to 42 percent of seller-fulfilled GMV in my case materials. Sellers declared one-day handling to win placement and hit it about 85 percent of the time. **Task.** Redesign the enrolment process so adopting is the seller's rational choice, safely. **Action.** I walked the funnel and designed refusal interviews: the stall was an unpriced trade, not a marketing problem. I rebuilt the offer as an all-or-nothing contract: transit automation, observed handling and a participating label earn scorecard protection, with a per-seller GMV-delta line showing the value in their own dollars. Every enrolment is shadow-run on the seller's own history before the flip, waves board only on published criteria, and I measured activations together with 30-day retention. **Result.** A design: the contract, the shadow gate, the wave criteria and a measurement pair that can't be gamed. Modeled at about $3.7M a year for every ten points of GMV enrolled."

S — The marketplace underwrites the promise, but the inputs (handling time, ship nodes, carriers) are configuration data thousands of sellers set themselves, optimistically and rarely updated. Managed-settings adoption stalled at **~38–42% of seller-fulfilled GMV**; declared 1-day handling hit **~85%** (case materials). The offer's value was unpriced; enrolments were counted, retention was not.

T — Diagnose the stall, redesign the enrolment process end to end, design rollout gates that protect both customer and seller, and define a measurement that stays honest after handoff.

A — Five gated phases, as designed:

- **Discovery: find the process defect.** Funnel walk plus interviews with enrolled, refused and churned sellers (the refusals teach most). Finding: fear of cost, loss of carrier control, distrust of the scorecard. An incentive-design defect. *Exit:* the biggest funnel drop-off named in sellers' own words.
- **Plan & Design: rebuild the offer.** (a) transit automation, (b) observed handling time computed from scan history (no more declared handling), (c) participating label; full bundle earns carrier-delay excusal and the fast badge where the math clears. A personalized "enrolment would raise your projected GMV by $X/month" line. *Exit:* contract and protection rules signed by product, seller ops and the scorecard owner.
- **Build & Test: validate before the flip.** Shadow-run each enrolling seller's recent orders under managed settings; projected accuracy and badge eligibility on their own history. *Exit:* shadow results within tolerance of projection on the pilot cohort.
- **Cutover: waves behind criteria.** Shadow-verified settings, observed-handling coverage, feed accuracy, protection rules armed. A wave that fails a criterion does not board the next cohort, publicly.

- **Hypercare: the honest pair.** Activations/week *and* 30-day retention; refusal reason codes feed back into the offer; kill condition: a protection promise the scorecard fails to honor stops enrolment until fixed.

R — Deliverable and modeled economics:

- **Process** One contract (three components, all-or-nothing), one pricing line per seller, a shadow gate before every flip, published wave criteria, a measurement pair (design).
- **$ ≈ $3.7M/yr per +10 pts** of enrolled GMV, modeled: 100K orders/wk × (15% − 3%) handling-miss reduction × 50% breach-through × $12 × 52 = $3,744,000. The 3% and 50% are illustrative; the $12 is the model's assumption.
- **Customer** The fast badge appears only where the math clears: the promise shown is the promise kept (design).

TRADE-OFF I MADE

Options: market harder · make the label purchase a hard cliff · tier the protection with bundle depth. **Chose:** tiered protection, carrots first. **Rejected:** the hard cliff, because sellers with negotiated carrier rates read it as a tax and churn, which is a strategic loss in an assortment-growth phase. **Cost:** a slower adoption curve and enforcement deferred until the marketplace's own fulfillment alternative scales. **Metric:** 30-day retention next to activations.

Failure / learning. The tempting metric was enrolments. Enrolments without retention is churn dressed up as growth, so retention went on the board as an equal. The lived lesson behind that: at Flexport, the customer count only meant something because graduation gates came first.

SAFE-SAY: "About three-point-seven million a year per ten points is modeled; it's a design case and I don't claim an adoption curve."

"Source?" "My Walmart-role war book: the 38–42% and 85% are in my case materials; the chain is my arithmetic."

20-SECOND VERSION

"Managed shipping had stalled near forty percent because sellers were trading control for an unpriced benefit. I redesigned enrolment as an insurance contract with a per-seller dollar line, a shadow run on each seller's own history before the flip, and waves gated on published criteria. It's a design case, modeled at about $3.7M a year per ten points enrolled."

Probing Q&A

Q1. How does this apply to non-specialists self-serving network changes?

Same three guardrails: show the outcome before the flip (shadow on their own data), make a bad flip reversible, and measure retention of the change, not just the count of changes. An AI-assisted config tool should preview the downstream effect and refuse a change it can't validate.

Q2. Why all-or-nothing?

Partial adoption lets a seller keep the risky declared handling and still claim protection. The all-or-nothing bundle makes the hedge self-selecting: a seller who trusts their own ops keeps control; one who doesn't converts.

Q3. What would kill the program?

One protection promise the scorecard fails to honor. So the kill condition is written before launch: stop enrolment until it's fixed.

Q4. What did you actually deliver?

Nothing in production; this is a design case. The delivered adoption-behind-gates record is Flexport: 7 to 68 customers behind published graduation criteria.

PART 4A — JAMES CABREROS — PROCESS IMPROVEMENT AND PLACEMENT ARCHITECTURE

Governed process design: promise policy, operating mechanisms, enrollment, and infrastructure flow

James Cabreros — 11:00 AM slot

Senior Manager, Supply Chain · placement architecture · process improvement · configuration governance

How to use this file. J1–J3 are Walmart Marketplace design cases. J4 is one end-to-end Google Fiber infrastructure supply-chain design followed by five zoomed STARs. Every design result is a proposed mechanism or a labeled model—not a production claim. Each is paired with a lived failure or run-experience analog so I can move to evidence if the interviewer asks, “Have you actually seen this break?”

Contents

J1 Walmart promise buffer — one governed dial

J2 Walmart promise-yield WBR + Andon

J3 Walmart managed-shipping enrollment funnel

J4 Google Fiber — one end-to-end infrastructure supply-chain map

J4A E3 + E11 vendor EDI/VMI → direct-procurement PO lifecycle

J4B E1 + E2 contractor truck stock → serial traceability

J4C E5 3PL reconciliation — “two books, one truth”

J4D E10 returns/RMA — escape routing by disposition

J4E E12 consignment/vending ledger — capacity signaling

Integrity key. record = lived source; **record-from-docs** = source artifact; **modeled** or **illustrative** = design math only. I designed and governed; client engineering/SAP teams built or would build. I do not claim I configured SAP, ran VMI, or delivered these design-case outcomes.

DESIGN CASE — NOT A DELIVERED RESULT

J1 · Walmart pre-purchase delivery experience — the governed promise-buffer dial (S19)

Placement-architecture hook: policy before configuration; one auditable business dial, shadow validation, peak regime change.
Paired lived record: Apple F4 / Elementum lead-time distributions and the real in-transit promise-rule miss.

60-SECOND PITCH

S — In a Walmart Marketplace design engagement, the same flat 1.10-day buffer sat on every seller/carrier cohort. On the illustrative twelve-cohort book it looked healthy at 95.8% accuracy, but it over-insured tight lanes and under-insured volatile ones. **T —** I had to turn a hidden model parameter into a governed business policy without claiming I built the promise engine. **A —** I decomposed the promise, compared four policies, recommended a risk-proportional buffer $b = k\sigma$, made k the one named dial, and designed four shadow weeks, a 95% promotion floor, one-flag rollback, and a pre-peak re-solve. **R —** In the illustrative model, fast-promise share moved 7.6%→39.6%, +32 points, at the same 95% floor; average promised day moved 3.09→2.75. That is modeled, not banked. The delivered artifact was the policy table, gate, and governance mechanism.

S — Situation. I was leading the promise-policy workstream for a marketplace design in which the customer saw one date but responsibility was split across seller handling, carrier transit, and a residual buffer. A flat buffer had no active owner, and a green portfolio average hid opposite cohort-level failures.

T — Task. I owned the decomposition, alternatives, test gates, and operating policy. I had to preserve a 95% modeled accuracy floor while recovering speed, and make the trade auditable by a business owner. Client data science and engineering owned the model and engine.

A — Action. I ran five gates: (1) **discover**—audit early-delivery waste and variation by cohort; (2) **design**—compare uniform, risk-proportional, minimum-days, and profit-optimal policies on one book; (3) **test**—prove that $k=1.645$ holds the 95% illustrative floor by cohort and stress Q4 variability; (4) **cut over**—compute the challenger in shadow for four consecutive weeks and keep the incumbent warm; (5) **govern**—publish k, p90 error, exceedance, and waste in the weekly header, with a named business owner and a peak reset date.

R — Result. The illustrative model produced 7.6%→39.6% fast-promise share and 3.09→2.75 average promised day at the held 95% floor. The economic line was about $255K/week, or about $13.3M annualized, **modeled** on an illustrative million-order weekly book; there is no production dollar. The real process result I claim is one signable policy, one reversible promotion gate, and one explicit owner.

TRADE-OFF I MADE. I chose one governed, risk-proportional dial over per-lane learned buffers. I knowingly left some modeled value on the table to gain explainability, auditability, and a one-flag rollback; volatile cohorts received slower promises on purpose so tight cohorts could become faster without spending the accuracy floor.

LIVED FAILURE / LEARNING. In my real inventory-promise work, my first in-transit rule was too conservative and starved dotcom of sellable units for about a week. I replaced the blanket rule with a per-lane promise window backed by observed lane data. That failure is why this design shadows against real orders and governs by cohort rather than trusting a portfolio average.

LP tags. Dive Deep—I went below a green 95.8% portfolio print to cohort variance. · **Invent and Simplify**—I reduced many micro-decisions to one governed dial. · **Customer Obsession**—I optimized the promise kept, not merely the date displayed. · **Have Backbone; Disagree and Commit**—I rejected a more opaque per-lane model for the first release.

SAFE-SAY. “The +32 points and all dollars are from the engagement’s illustrative twelve-cohort model; I claim the decision instrument, not a production outcome.”
“My source is master story S19; the lived analog is the signed inventory-promise work and its documented in-transit-rule correction.”

20-SECOND VERSION

I took a flat promise buffer that was simultaneously too slow and too risky and designed one risk-proportional dial, shadowed for four weeks, promoted only at a 95% floor, rolled back in one flag, and reset before peak. The illustrative model bought +32 points of fast-promise share; what I claim is the governed mechanism, not production P&L.

FOUR PROBES

1 · Why not optimize each lane independently?

That is a higher modeled frontier but a weaker first operating policy. I started with one explainable dial; I would graduate to lane-level tuning only after shadow evidence showed material incremental value and Finance accepted the breach economics.

2 · What stops a peak-season accuracy collapse?

The dial is regime-specific. The Q4 drill showed a frozen summer setting breaking the floor, so the owner must re-solve and publish the peak value before October; breach of the shadow floor blocks promotion.

3 · What exactly did you own?

The promise identity, waste audit, four-policy decision table, stress proof, promotion/rollback gates, and governance handoff. Client teams owned the production model and engine.

4 · Where is the process-improvement mechanism?

Configuration can no longer drift silently. Every change has an owner, a visible dial, a cohort-level tail read, a shadow result, a promotion decision, and a rollback path.

CONFIGURATION-GOVERNANCE HANDOFF CARD

CONTROL	BEFORE DEPLOYMENT	AFTER DEPLOYMENT
Policy	Owner signs floor, cohort grain, and peak regime.	Dial and model version appear in every review.
Validation	Four shadow weeks; cohort tails clear the floor.	Waste, p90 error, exceedance, and contacts trend together.
Change	One flag; incumbent remains warm; rollback trigger written.	Breach rolls back, starts cause review, and blocks expansion.
Correction	Peak drill before launch.	Pre-peak re-solve becomes a dated annual control.

DESIGN CASE — OPERATING MECHANISM, NOT A PRODUCTION CLAIM

J2 · Walmart weekly business review + Andon for promise yield (S20)

Configuration-governance hook: outputs over owned inputs; one definition, denominator, owner, floor, action, and verification loop. **Paired lived record:** the Flexport weekly review I ran and my lived scheduler/status-control failures.

60-SECOND PITCH

S — Walmart's pre-purchase promise was split across seller, carrier, model, and engine teams; 30-day windows hid a degrading seller-lane cell and a red week became a blame meeting. **T —** I had to design the operating mechanism, not another dashboard. **A —** I established one glossary and event source, seven customer outputs over ten owned inputs, Promise Yield as fast share × accuracy, a factor decomposition that names seller, carrier, or buffer, Tuesday pre-wires, mix-adjusted twins, and a seven-day cell-level Andon that acts within 24 hours while keeping the 30-day clock for seller consequences. **R —** The design moved attribution from negotiation to minutes and detection-to-action from up to 30 days to under 24 hours. The sample Promise Yield baseline was 41.5%; about $0.58M per caught episode is modeled, never annualized.

S — Situation. I found outputs owned by a committee, three date clocks, denominator drift, and aggregate carrier performance that could look green nationally while one region failed customers.

T — Task. I owned the metric architecture, thresholds, causal roll-up, meeting rhythm, and control loop. Client engineering owned pipelines; business owners had to own levers after handoff.

A — Action. I gated the mechanism: **discover** one definition, owner, grain, date basis, and denominator per metric; **design** seven outputs over ten turnable inputs, hard reds on policy floors, and one joint headline; **test** the factor identity on six sample weeks and inject a Southeast carrier degradation; **launch** Monday freeze, Tuesday decision, every red pre-wired with cause/owner/date; **control** with raw and mix-adjusted twins plus a seven-day EWMA/CUSUM Andon at seller-lane grain, sustained 2× baseline and at least 30 orders, reversible badge/buffer action within 24 hours.

R — Result. On the sample drill, factor attribution took minutes rather than days. The proposed control loop acted in under 24 hours instead of waiting on a 30-day window. Promise Yield was 43.6% fast share × 95.2% accuracy ≈ 41.5% **sample baseline**. The ~$0.58M episode line is **modeled** from three weeks earlier action; I do not claim a live output move.

TRADE-OFF I MADE. I kept the stable 30-day clock for seller consequences but used a fast seven-day clock for reversible customer protection. I rejected a larger board and instant punitive action: speed belongs at cell/badge level; fairness belongs at scorecard level.

LIVED FAILURE / LEARNING. In a real peak incident, a scheduler failed silently and the business detected it from aged promises. I added a heartbeat and "detect within one interval" rule. In the production Flexport WBR, I also learned that two disagreeing numbers must be reconciled before comparison. Those failures are why this design has freshness, denominator, and heartbeat controls—not just colored tiles.

LP tags. Insist on the Highest Standards—hard floors can stop expansion. · **Earn Trust**—definitions and denominators are visible. · **Dive Deep**—factor math attributes the miss. · **Ownership**—every red has one owner, date, and verify step.

SAFE-SAY. "41.5% is the engagement sample baseline; the sub-24-hour Andon and ~$0.58M per episode are designed/modeled, not a live Walmart result."
"The source is master S20; my lived operating analog is the production WBR and the scheduler-heartbeat corrective action."

20-SECOND VERSION

I designed a promise WBR where every output decomposes into a turnable input with one owner, every red arrives pre-wired, and a cell-level Andon protects customers in under 24 hours while the fair 30-day seller clock stays intact. The engagement proved attribution on sample weeks; I do not claim live output movement.

FOUR PROBES

1 · Why Promise Yield?

Accuracy alone rewards slow promises; fast share alone rewards broken ones. Their product makes the trade visible, while the next line decomposes it so the composite cannot hide a cause.

2 · How do you avoid noisy Andons?

A sustained control signal, a 30-order floor, replay against stable cells, and a designed false-trip bar under 5%. The action is reversible and auto-restores on recovery.

3 · Who can stop a rollout?

A hard policy-floor red stops cohort expansion; the Andon can pull a cell's fast badge; the output owner can hold a launch that changes a metric definition.

4 · What if an input moves but the output does not?

The verify step declares the causal map wrong and reopens it. A review that cannot falsify its own model becomes numerology.

DESIGN CASE — WAVE ONE MECHANICS; ADOPTION CURVE UNCLAIMED

J3 · Walmart stalled managed-shipping program — enrollment-funnel process redesign (S21)

Self-service/configuration hook: diagnose the funnel, make the contract explicit, verify configuration in shadow, graduate cohorts on counted gates. **Paired lived record:** Elementum lane onboarding and the real "instrumented too late" miss.

60-SECOND PITCH

S — Walmart's managed shipping settings had stalled at roughly 38–42% of seller-fulfilled GMV. Sellers declared one-day handling but hit it about 85% of the time, while enrollment asked them to surrender control for a benefit they could not price. **T —** I had to redesign the process from "market the feature harder" to a rational, measurable exchange. **A —** I mapped enrolled/refused/churned sellers through the funnel, reframed the offer as transit automation + observed handling + scorecard protection, designed a personalized benefit line, shadow-ran each seller on its own history, and boarded waves only when handling coverage, inventory-feed quality, and protection rules cleared. I paired activations with 30-day retention. **R —** The design delivered the signed contract and wave-one mechanics; ≈$3.7M/year per ten points of enrolled GMV was **modeled**. I do not claim the later adoption curve.

S — Situation. I saw a process treated as a communications problem even though the refusal was economically rational: loss of carrier control, fear of cost, and distrust that the scorecard would honor carrier-delay protection.

T — Task. I owned the refusal diagnosis, contract structure, shadow gate, wave graduation, and measurement pair. Client product/engineering owned Seller Center and observed-handling computation.

A — Action. I interviewed enrolled, refused, and churned sellers and named the biggest funnel drop; wrote a bundle with explicit rights and obligations; replaced self-declared handling with observed scan history; made benefit visible in the seller's own modeled GMV; shadowed recent orders before flipping configuration; published wave criteria—settings verified, handling coverage, node inventory feed, protection armed—and stopped the next wave on any miss; measured activations and 30-day retention together, with a kill condition if scorecard protection failed.

R — Result. The claimed output is a signed design, one gated wave, and an honest measurement pair. The baseline 38–42% and 85% are **record-from-docs**. The ≈$3.7M/year per +10 points is **modeled** from handling-miss reduction; no post-wave adoption result is claimed.

TRADE-OFF I MADE. I favored carrots and tiered protection over an aggressive all-or-nothing enforcement cliff. That made the contract less pure and slower to standardize, but protected assortment and seller trust while the client's own fulfillment alternative was not yet a credible substitute.

LIVED FAILURE / LEARNING. In my real thousand-lane onboarding, I measured completeness from day one but instrumented tender acceptance only from cohort three; that delayed discovery of a carrier-data problem by two cohorts. Here, acceptance/retention and refusal codes exist before wave one. I learned that a rollout gate added after launch is only a report.

LP tags. Customer Obsession—observed handling protects the buyer's promise. · **Earn Trust**—seller protection is explicit and testable. · **Think Big**—the offer can scale through self-selection, not persuasion. · **Deliver Results**—waves graduate on evidence, not calendar.

SAFE-SAY. "The 38–42% and 85% are engagement-document baselines; ≈$3.7M is modeled per ten enrolled-GMV points. I claim the contract and wave mechanics, not the subsequent adoption curve."
"The source is master S21; the lived gate lesson is Apple F1's cohort onboarding record."

20-SECOND VERSION

I treated stalled adoption as an incentive and process problem: explicit insurance-like protection, observed rather than declared handling, seller-specific value, shadow verification, and waves gated on configuration and feed quality. Activations are paired with 30-day retention. Wave-one mechanics are the result; the later curve is not mine to claim.

FOUR PROBES

1 · Why did sellers refuse?

They traded away carrier and configuration control for protection that was real but weakly specified and unpriced. More banners would not change that contract.

2 · What is the pre-deployment validation?

Replay recent seller orders under observed handling and managed transit; compare projected accuracy and badge eligibility; arm scorecard protection; then flip only inside tolerance.

3 · What metric cannot be gamed?

Activations plus 30-day retention and protected-GMV share. Activations alone turn churn into apparent growth.

4 · When do you stop enrollment?

If the scorecard penalizes a carrier delay the contract promised to excuse, enrollment stops until the protection path reconciles. Trust is an invariant, not a follow-up ticket.

WAVE-GRADUATION CARD

GATE	PASS EVIDENCE	FAILURE ROUTE
Configuration	Observed handling and managed-transit replay within tolerance.	Keep seller on current settings; fix cause.
Connectivity	Node inventory feed complete and fresh.	Block fast badge and next-wave boarding.
Contract	Scorecard protection armed and tested.	Stop enrollment; reconcile protection path.
Adoption quality	Activation, 30-day retention, and protected GMV read together.	Refusal/churn reason re-enters design backlog.

DESIGN CASE — ONE END-TO-END PROCESS MAP

J4 · Google Fiber infrastructure supply chain — placement, connectivity, capacity, and escape routing

North-star invariant: every serialized unit is in exactly one state, at one location, under one owner; every transition has one durable document; every system-to-system hop reconciles. **Voice:** I would own the process, contracts, gates, and governance; SAP/CRM/3PL teams configure and build.

STAGE	FLOW / DOCUMENT / CONTROL	CONFIGURATION GOVERNANCE	JAMES-BULLET MAPPING
1 · E3 signal	Vendor 830/852 forecast/activity → 855 dated confirmation → 856 ASN + serials; VMI min/max from measured lead-time tails.	≥95% valid-ASN cohort gate; undated ack = unconfirmed; weak vendor stays on portal.	Inbound connectivity; capacity signaling.
2 · E11 buy	Build plan/MRP → PR → approved direct PO/850 → confirmed date → ASN → receipt/101 → invoice/810.	Direct stock/project stock in SAP; indirect spend outside stock; PO changes require reconfirmation.	Capacity signals for new node types.
3 · E1/E2 deploy	3PL → contractor/van stock → install by serial → CRM asset; crossdock bypasses storage for node kits.	Van as governed location; scan every transfer; install from wrong van holds; offline events replay idempotently.	Outbound connectivity; crossdock enablement.
4 · E4 promise	CRM order → SAP fulfillment → 3PL/field status → CRM; correlation id follows every hop.	One writer/status; unknown never maps to shipped; daily sent=created=delivered=status-returned.	Placement/order architecture.
5 · E5 reconcile	3PL 846 + receipts/ship confirms vs SAP by SKU×location×state×serial; “two books, one truth.”	Reason code timing/mapping/status/physical; lower-of-two while unresolved; only physical becomes adjustment.	Post-deploy validation; auditability.
6 · E10 escape	Return/RMA → untested → premise/central test → refurb A/B | repair | RTV | scrap.	No test/no grade/no promise; warranty and vendor-RMA checks route the exception.	Escape routing.
7 · E12 settle	Consignment receipt creates custody; install/dispense creates liability; refill/count; monthly settlement.	Append-only event ledger; count changes book only by document; capacity/route signal from par and stockout risk.	Capacity signaling; node configuration.

20-SECOND ARCHITECTURE ANSWER

I would run one serial-grain spine from vendor signal to PO, 3PL, van, CRM asset, return disposition, and settlement. Each hop has one owner and durable document; each node type has a configuration template and validation gate; E5 reconciles the physical and financial books; E10 is the governed escape route; E12 turns consumption into the capacity and liability signal.

DESIGN CASE — E3 + E11 · INBOUND CONNECTIVITY + CAPACITY SIGNALING

J4A · Vendor EDI/VMI → direct-procurement PO lifecycle for long-lead equipment

Lived analog: Elementum EDI onboarding—one thousand lanes requested, the 597 carrying 80% of spend first; ≥95% data-quality cohort gate. **Honesty:** I have run vendor/transport EDI onboarding, not a VMI program; VMI/consignment is the designed pattern.

60-SECOND PITCH

S — In the Google Fiber design, node equipment has 12–40-week lead times, confirmations in email, and build crews exposed to supplier variance. **T —** I would create one demand-to-receipt process whose dates harden as evidence improves and whose vendor signal can drive capacity. **A —** I would connect build-plan need to PR, approved PO/850, dated 855 confirmation, serialized 856 ASN, receipt, and 810 invoice; publish requested-versus-confirmed gap; rank expediting by milestone at risk; and, for strategic suppliers, share 830/852 demand/activity with min/max based on measured lead-time tails. A vendor cannot activate until valid ASNs clear 95%; undated acknowledgments remain unconfirmed. **R —** The proposed bar is ≥95% on-time to the vendor's confirmed date and zero PO lines unconfirmed after 48 hours. Any dollar is illustrative; the mechanism produces a capacity signal leaders can trust.

S — Situation. I would start with scattered demand, allocation risk, email confirmations, and requested dates incorrectly treated as supply. That creates false capacity at new nodes and heroic expediting.

T — Task. I would own the cross-functional process, document contract, activation gate, vendor scorecard, and exception ownership. Procurement owns the commercial terms; Planning owns demand; SAP and integration teams configure.

A — Action. I would define direct stock/project stock in SAP and keep services/expensed spend outside inventory; require PR→release→PO with no spreadsheet bypass; turn 855 date/quantity into the MRP-relevant supply; expose every line without a dated confirmation after 48 hours; validate serialized ASNs and acknowledgments before activation; sequence suppliers by criticality and spend; measure requested-date gap separately from confirmed-date reliability; for qualified VMI suppliers, send forecast/activity and set min/max from measured p90 lead time, with monthly drift review and Finance choosing own stock versus consignment.

R — Result. This design yields one auditable date chain and one capacity signal: receipts on/before confirmed date ≥95%, valid ASNs ≥95%, unconfirmed-after-48-hours → 0, receipts without ASN → 0. An illustrative avoided-idle-week value is ~$50K; I would ask Finance for the actual crew/deferred-activation cost before sizing impact.

TRADE-OFF I MADE. I would delay activation for weak-data suppliers and let them use a portal template until they graduate. That costs speed in month one but prevents a bad ASN from contaminating serial, receipt, capacity, and Finance downstream. For fixed sites I would use project stock; for pooled equipment I would preserve aggregation rather than fragment inventory by project.

LIVED FAILURE / LEARNING. In my real lane onboarding, completeness was instrumented from day one but tender acceptance only from cohort three, so a carrier-data issue surfaced two cohorts late. I now require both "message is valid" and "business transaction succeeded" before a vendor graduates.

LP tags. Ownership—one owner and exception clock per PO line. · **Dive Deep**—request and confirmation are separate causal metrics. · **Insist on the Highest Standards**—the ASN gate blocks activation. · **Deliver Results**—expediting ranks the milestone at risk, not the loudest requester.

SAFE-SAY. "Twelve-to-forty weeks and any dollars here are illustrative design inputs; the one-thousand-lane/597-first EDI wave and its data-quality gate are my lived record."
"I have not run VMI; I would own its process and controls while Procurement, Finance, and SAP owners execute their parts."

20-SECOND VERSION

I would turn long-lead buying into one dated chain from build signal to confirmed PO, serialized ASN, receipt, and invoice. Vendors graduate only after valid messages and successful transactions; requested-versus-confirmed gap is separate from vendor reliability; qualified VMI uses measured tails for min/max. The capacity signal is confirmed supply, not hope.

FOUR PROBES

1 · What if an 855 says "accepted" without a date?

It is unconfirmed, visible after 48 hours, and excluded from trusted capacity. "Acknowledged" is transport success, not a supply commitment.

2 · Own stock or consignment?

Model both. Consignment keeps vendor ownership until consumption and helps working capital; own stock simplifies accounting. Finance chooses explicitly.

3 · How do you prioritize scarce supply?

Milestone-at-risk × customer/build impact, constrained by qualification and committed projects—not who escalates first.

4 · What is the kill switch?

Disable the vendor map/cohort, preserve the last valid confirmation, route new transactions through the portal, and keep receipts blocked until serial/quantity reconcile.

DESIGN CASE — E1 + E2 · OUTBOUND CONNECTIVITY + CROSSDOCK ENABLEMENT

J4B · Contractor truck stock → serial-number chain from warehouse to premise

Lived analog: owner-partitioned inventory and audited transitions in Sephora; real RF-device readiness miss. **Primary process metric:** unaccounted units per contractor and complete serial chain.

60-SECOND PITCH

S — In the field-inventory design, the 3PL saw a shipment, the contractor saw a van, CRM saw an assigned technician, and Finance saw stock—but no one could prove where a serialized unit sat. **T —** I would make every truck a governed node and every install an auditable state transition. **A —** I would model 3PL, crossdock, van, installed, and returns as explicit stocks; scan serials on ASN, issue, transfer, install, swap, and return; let CRM read only the assigned tech's available stock; replay offline events by serial with idempotency; gate replenishment on a posted weekly count; and reconcile SAP, 3PL, field app, and CRM daily. **R —** Proposed bars are ≥99% same-day install posts, 100% weekly counts, zero unexplained serials, and zero "van said yes, book said no" reschedules. Volumes and dollars remain illustrative.

S — Situation. I would treat "unaccounted" as an undocumented flow before calling it loss. A truck is inventory outside a warehouse; without a location, serial state, and document, the system guarantees phantom availability.

T — Task. I would own the state model, node template, event contract, exception queue, crossdock decision, count policy, and activation checklist. Field Ops owns counts; Inventory Control owns the book; SAP/3PL/CRM teams build.

A — Action. I would create a location per contractor/truck; 3PL→van is a scanned transfer, van→premise an install by serial, swap a paired scan-out/scan-in, and return a move to untested stock. Crossdock applies when a node kit is preassigned and ASN/serial/order all match; otherwise it enters 3PL stock. Every event uses document+line+serial, offline events replay in serial order, unknown/wrong-location installs hold, counts post adjustments only with reason, and a missed weekly count blocks new issues with a direct-fulfillment escape route.

R — Result. The design makes the complete serial chain the quality metric: ASN→receipt→van→install/CRM asset→return. Targets: serial-state accuracy ≥99.5%, same-day install posting ≥99%, posted weekly counts 100%, unaccounted near zero. Illustrative sizing in the design is 500 vans × two unexplained units/month × $150 ≈ $1.8M/year of stock without a reliable owner—not claimed savings.

TRADE-OFF I MADE. Per-serial scanning and count-as-gate slow receiving and weekly replenishment; I accept that cost because silent phantom stock creates failed installs and unauditable chargebacks. Crossdock removes touches only when identity is already proven; otherwise the 3PL validation step stays.

LIVED FAILURE / LEARNING. On a real DC migration, device scripts for hundreds of RF devices were not proven before training; training moved 1.5 weeks, although go-live held. I learned physical/device readiness must be an entrance criterion with a named owner, not a task buried under software readiness.

LP tags. Invent and Simplify—one state machine across four systems. · **Highest Standards**—wrong-location serials hold rather than auto-fix. · **Bias for Action**—offline capture plus ordered replay keeps field work moving. · **Ownership**—count and chargeback responsibilities are explicit.

SAFE-SAY. "The ≥99.5% bar and van-dollar example are illustrative design targets; the RF-device delay and owner-partitioned inventory controls are lived records."
"I designed the state and integration contract; I did not configure the SAP serial profile."

20-SECOND VERSION

I would make every van a governed inventory node and every serial move a document: ASN, 3PL receipt, van issue, install/CRM asset, swap, and return. Crossdock is allowed only on a three-way identity match; offline events replay idempotently; missed counts stop replenishment. The result is a complete serial chain, not a better spreadsheet.

FOUR PROBES

1 · Why a location, not a spreadsheet?

The client owns the unit and Finance must locate it. A spreadsheet creates a second book; a governed location makes transfer, count, and adjustment auditable.

2 · How does crossdock stay safe?

PO/ASN serial, node kit, work order, and assigned technician must match before bypassing storage; any mismatch routes to controlled 3PL receipt.

3 · Field app is offline—then what?

Mint and persist an idempotency key on device, timestamp, replay in order per serial, and expose "captured not posted" as timing—not loss.

4 · What prevents false chargebacks?

Only a posted physical-inventory document with reason can feed chargeback. Missing events trigger reconciliation and a recount, not an accusation.

NEW-NODE ACTIVATION CARD

LAYER	REQUIRED BEFORE VOLUME	ESCAPE ROUTE
Identity	Node/location, contractor, truck, kit, and serial policy configured.	No identity match: receive to controlled 3PL stock.
Connectivity	ASN, issue, install, swap, return, offline replay all pass.	Freeze node issues; fulfill direct from 3PL.
Physical	Devices proven; first count posted; capacity/route confirmed.	Manual scan/count path, not silent spreadsheet.
Audit	Three-way serial reconciliation clean.	Hold wrong-state serial; reason-code and correct.

DESIGN CASE — E5 · POST-DEPLOYMENT VALIDATION + AUDITABILITY

J4C · 3PL reconciliation — “two books, one truth”

Lived analog: three production-scale mock reconciliations moved variance 7%→1.8%→0.3% against a pre-published 0.5% tolerance (record). **Placement hook:** lower-of-two promise basis while configuration drift is unresolved.

60-SECOND PITCH

S — In the design, SAP holds the financial/storage-location book while a 3PL WMS holds the physical bin/serial truth; timing, status, and unit-of-measure differences make the delta look like shrink. **T —** I would protect customers and Finance without letting either system “win” by assertion. **A —** I would align SKU×location×state×serial, compare daily snapshots against an in-flight ledger, classify every delta as timing, mapping, status, or physical, promise from the lower of SAP/WMS until resolved, and allow only physical differences to become referenced adjustments. Finance publishes tolerance before the first comparison; serials have zero tolerance. **R —** The proposed result is consecutive days inside tolerance, zero unexplained serials, 100% reason-coded adjustments, and no silent month-end true-up. The lived proof is the mock arc that closed at 0.3% against 0.5%.

S — Situation. I would start where two valid books disagree at different grains: WMS bin/status/serial versus SAP location/stock type. Ad hoc adjustment hides whether the defect is a late message, bad map, wrong state, or physical loss.

T — Task. I would own the grain contract, status/UoM maps, in-flight rules, tolerance, reason taxonomy, owner/SLA, promise safety rule, and close control. Finance signs tolerance; the 3PL owns physical evidence; Inventory Control owns posting.

A — Action. I would ingest daily 846 inventory plus 944 receipts, 945 ship confirms, and 947 adjustments; roll bins to locations and compare serials as sets; subtract expected in-flight documents before calling variance; quarantine unknown statuses rather than map them to unrestricted; route timing to integration, mapping to master data, status to operations, and physical to count/research; expose aging and owner; post 701/702 only from a unique 3PL adjustment id; keep promising on min(SAP,WMS) until closure.

R — Result. Designed bars: rows outside tolerance → 0 on consecutive days, unexplained serials = 0, adjustments with reason = 100%, unposted confirms over 48 hours = 0. Illustrative sizing: on $20M held at 3PL, moving unexplained delta from 2% to 0.5% resolves about $300K of uncertainty—not claimed savings.

TRADE-OFF I MADE. Lower-of-two under-promises while a delta stands, and zero serial tolerance creates exceptions. I accept temporary capacity loss over a customer promise against phantom stock or an unexplained asset at close.

LIVED FAILURE / LEARNING. In my real migration, mock one was 7% off because of UoM, location, and status vocabulary; mock two reached 1.8% and exposed in-transit timing; a separate in-transit batch and 72-hour freeze brought mock three to 0.3%. I learned never to celebrate a shrinking total without a named cause class.

LP tags. Earn Trust—Finance sets the tolerance before results. · **Dive Deep**—the delta is decomposed by cause. · **Customer Obsession**—lower-of-two blocks phantom promises. · **Highest Standards**—serial uncertainty has zero tolerance.

SAFE-SAY. “7%→1.8%→0.3% against 0.5% is the lived migration record; the $20M/$300K line is illustrative design sizing.” “The source is master E5 paired with the recorded mock-cutover reconciliation; I claim the control design, not a Google Fiber outcome.”

20-SECOND VERSION

I reconcile SAP and the 3PL at aligned grain, subtract in-flight documents, classify the remainder into timing/mapping/status/physical, and promise from the lower book until resolved. Only physical differences become controlled adjustments. The lived analog moved three mocks from 7% to 0.3% against a 0.5% gate.

FOUR PROBES

1 · Which book wins?

Neither automatically. SAP is Finance’s book, WMS is physical truth; the reason-coded investigation decides. Promising uses the lower while they disagree.

2 · How do you prevent replayed adjustments?

Snapshot key = date+warehouse; adjustment id is unique and referenced by the SAP document. Replay returns the existing post.

3 · What if an unknown status arrives?

Hold it as unknown and unpromisable. Never default an unmapped state to unrestricted.

4 · What makes this governance, not reporting?

The report changes behavior: lower-of-two constrains promise, aging escalates owners, tolerance gates close, and only a governed cause can post an adjustment.

DESIGN CASE — E10 · ESCAPE ROUTING / REVERSE FLOW

J4D · Returns/RMA — premise test → refurb / RTV / scrap

Lived analog: contract-manufacturer disposition forum and a real partial-extract failure that looked like mass deletion. **Architecture hook:** exceptions do not bypass the main process; they enter a governed state machine.

60-SECOND PITCH

S — In the reverse-flow design, disconnected and swapped equipment could reach a returns bin, then disappear into "returned" without test, grade, warranty recovery, or a reliable serial state. **T —** I would create escape routing that preserves customer speed without turning exceptions into unaudited shortcuts. **A —** I would open an RMA by serial/reason, receive into returns-untested, consolidate to a standard test cell, and let the test event route the same serial to refurb A/B, repair, blocked failure, vendor return, or certified scrap. No test means no grade and no promise; warranty and vendor-RMA rules block the wrong disposition; aging and expected-versus-received credits sit in one weekly forum. **R —** Proposed bars are ≥95% disposition within 14 days, ≥80% warranty recovery on eligible failures, zero untested units made available, and 100% scrap certificates. All economics are illustrative.

S — Situation. I would treat "returned" as a flow, not a final state. A unit can be physically back but still unsafe to promise, financially eligible for vendor recovery, or absent from the book because the field event never posted.

T — Task. I would own the legal states/transitions, reason/grade vocabulary, SLA, warranty logic, escape paths, credit reconciliation, and disposition forum. Service owns the case; the test partner owns evidence; Finance owns write-off/credit.

A — Action. I would require serial+reason at initiation; post pickup/tech return into untested stock; preserve identity through consolidation; accept test results only for serials in the expected state; use grade as an attribute, never renumber; compute warranty from the serial's contract start event; require vendor RMA before shipping RTV; prevent in-warranty scrap unless Finance approves; reconcile return initiated → received → tested → dispositioned and expected → received credit; escalate aging by state and reason.

R — Result. The designed result is a measurable escape route: ≥95% within 14 days, warranty recovery ≥80% of eligible failures, untested available = 0, RTV without vendor RMA = 0, scrap certificate = 100%. A 48K-return/$3.1M-net refurb case in E10 is **illustrative**, not a delivered claim.

TRADE-OFF I MADE. I chose centralized, standardized testing over faster grading on every truck. It adds a consolidation hop and days, but avoids inconsistent grades and a second truck roll caused by promising an untested unit. During surges, availability waits; quality does not.

LIVED FAILURE / LEARNING. In my real contract-manufacturer data program, an unflagged partial extract looked like thousands of deleted components. I added a completeness flag as a hard stop only by wave three—later than I should have. The standing disposition call then caught a wave-two yield gap as one mapping row. That is why incomplete return/test feeds cannot advance state here.

LP tags. Customer Obsession—untested stock never reaches a premise. · **Ownership**—each disposition and credit has an owner. · **Invent and Simplify**—one serial state machine replaces side queues. · **Frugality**—refurb and warranty recovery avoid needless new units.

SAFE-SAY. "The 14-day/80% bars and all return economics are illustrative design targets; the completeness-flag miss and weekly disposition forum are lived."
"I have not run an RMA program end to end; I have run the state, data-quality, and disposition-control analog."

20-SECOND VERSION

I would route every returned serial through one legal chain: RMA, untested receipt, standard test, then refurb/repair/RTV/scrap. No complete feed, no state advance; no test, no promise; no vendor RMA, no return shipment. Aging and credits close in one disposition forum.

FOUR PROBES

1 · Why keep the same serial after refurb?

Identity and warranty history must remain continuous. Grade changes; the serial does not.

2 · What is escape routing here?

A failed normal transition enters a named state with an owner and legal exits—it never jumps directly to unrestricted, write-off, or a spreadsheet queue.

3 · How do you stop warranty leakage?

Eligibility derives from the serial's contract start event; in-warranty scrap is rule-blocked; RTV requires vendor authorization; expected credits reconcile to receipts.

4 · What stops an incomplete file?

A completeness manifest with counts and sequence; absent/partial manifests hold the whole batch. Partial truth cannot move serial state.

DESIGN CASE — E12 · NODE CAPACITY SIGNALING + CONSIGNMENT LEDGER

J4E · A tech van as a vending machine — custody, consumption, replenishment, settlement

Lived analog: idempotent inventory decrement/reconciliation and a real status-mapping failure in which legal events did not advance state. **Key idea:** the van is the machine, install is dispense, refill is replenishment, kit is planogram.

60-SECOND PITCH

S — In the Google Fiber design, hundreds of field nodes can hold vendor-owned equipment, work offline, consume at install, and need replenishment before the next route. A receipt proves custody, not liability. **T —** I would create one event ledger that supports inventory, capacity, and Finance without double-consumption. **A —** I would receive consignment by serial, mint an install event at the edge before state changes, replay idempotently after reconnect, post consumption only at verified install, set van par from demand over review+lead time plus variability, rank refills by stockout risk×customer impact, reconcile every count to the ledger, and settle consumed units monthly. **R —** Proposed bars are ≥98% fill, zero duplicate consumption, 100% count-backed adjustments, and ledger backlog drained within ten minutes of reconnect. The working-capital example is illustrative, not claimed.

S — Situation. I would start with a configuration problem disguised as inventory: node capacity, ownership, offline events, and refill policy differ by contractor and market, so uncontrolled local defaults create both stockouts and settlement disputes.

T — Task. I would own the node template, event/state contract, par policy, refill priority, offline/duplicate controls, reconciliation, and settlement rule. Field Ops owns counts; Planning owns demand; Finance and Procurement own consignment terms.

A — Action. I would register each van/node with capacity, kit/planogram, owner, route, and connectivity policy; receive vendor-owned stock into a consignment state; persist event id = node×slot/SKU×sequence before install; post consumption once and create the CRM asset; use observed demand and measured replenishment lead time for par capped by physical capacity; signal overflow by shortening route interval rather than inventing capacity; compare pre-refill count to ledger and reason-code shrink; settle consumed units, delivery notes, and counts as a three-way match.

R — Result. Designed outcome: fill ≥98%, duplicate consumption = 0, count-backed adjustments = 100%, online ledger latency p95 under 60 seconds, reconnect drain under 10 minutes. Illustrative working-capital sizing—500 vans×30 units×$150 ≈ $2.25M held vendor-owned until install—is a Finance decision aid, not a result.

TRADE-OFF I MADE. Consignment defers cash but adds ownership states, settlement, and supplier reconciliation. I would use it for expensive, stable, high-volume kit components; I would keep volatile or low-value items as owned stock. If physical capacity caps par, I change route cadence—not hide the shortage in a higher target.

LIVED FAILURE / LEARNING. In a real visibility program, events arrived legally but the scraper and application used different status vocabularies, leaving roughly half the containers stuck in “verification in progress.” I traced the hops, added a mapping layer and contract tests. Here, unknown install/consumption states hold and alert; they never default to consumed or available.

LP tags. Think Big—one node pattern scales across a field fleet. · **Frugality**—consignment is an explicit working-capital lever. · **Dive Deep**—capacity and route cadence are separated. · **Earn Trust**—the supplier settlement is reproducible from events and counts.

SAFE-SAY. “The 98% bar, latency bars, and $2.25M example are illustrative; I have not run a consignment or vending program.”
“My lived evidence is the idempotent decrement/reconciliation pattern and the status-vocabulary failure; I claim the architecture and controls.”

20-SECOND VERSION

I treat a van like a vending node: receipt creates custody, install creates consumption and liability, count reconciles the ledger, and refill follows measured demand and route lead time. Events are edge-minted and idempotent; unknown states hold; monthly settlement reproduces from consumption, delivery notes, and counts.

FOUR PROBES

1 · Why consignment?

For expensive predictable items, it shifts working capital until install. It is not free: settlement and reconciliation complexity must be worth the capital benefit.

2 · How do you handle offline ordering?

Persist a monotonic node sequence before the physical event, replay in order, dedupe server-side, and expose backlog age; never order by wall-clock.

3 · What if par exceeds capacity?

Capacity is a hard constraint. Shorten route interval, re-slot the kit, or add a node; do not publish an impossible par.

4 · How does this signal a new node type?

The node template carries kit, capacity, demand class, route, ownership, and connectivity policy; rollout is blocked until its event, count, and settlement paths validate.

CAPACITY-SIGNAL CARD

SIGNAL	DECISION	GOVERNANCE CHECK
Demand vs par	Refill normal route.	Observed installs, not requested kit, drive usage.
Par > physical capacity	Shorten interval, re-slot, or add node.	Impossible par cannot publish.
Ledger ≠ count	Hold settlement delta; reason-code shrink.	Count changes book only through a document.
Backlog / stale heartbeat	Conservative availability; drain ordered events.	Unknown state never defaults to available or consumed.

Part 4B — James Cabreros (11:00 slot; schedule listed Zhaowen Lan) — Sr Manager Supply Chain, placement architecture · process improvement · configuration governance

Amazon — Senior Supply Chain Manager, NACF Supply Chain (L6) · Rajesh Rishiyur Chandrasekaran · Friday, October 30, 2026

Six lived-record process-improvement stories, one of them a full failure

S17 carrier-bid process · S10 Austria routing-guide data quality · S15 change governance · A4 Crux decommission (apples-to-apples lens) · L22 Customs/FFA ownership at work-item grain · G3 late security review (FAILURE, 3-level probes)

COMPANION TO THE JAMES FRONT MATTER (CRAM SHEET, HIS BULLETS → MY STORIES, TRADE-OFF LEDGER, TOOLKIT) IN *AMAZON-NACF-PANEL-4-CABREROS-PROCESS-STAR-KIMI-K3* AND TO UDC PACK B3 (NODE ENABLEMENT) AND B6 (RETAIL END-TO-END NEAR-MISS). THIS FILE ADDS STORIES ONLY; IT DOES NOT REPEAT THOSE.

How to use this file in the room. James leads a legacy placement-rules-engine migration to a centralized policy platform, AI-assisted configuration tooling, crossdock / escape-routing / capacity-signalling design, and configuration governance (pre-deployment validation, change-management SOPs, post-incident corrective actions, auditability across hundreds of weekly changes). Every story below is a *process* story told by the person who owned the rule, the gate or the boundary — not the award, not the build. Each ends with a line that maps it to one of his bullets. The failure story (G3) is told in full with three levels of probing, because he will ask for one. Nothing in this file is a design case.

Integrity rules on every page: every number carries a basis label — **record** (Apple v11 / master packet), **record-from-docs** (a page of a source document), **modeled** (my model, inputs stated), **illustrative**. S17 claims no award dollar. A4's $185,892 ARR is the documented legacy base, not a one-period loss. L22's result is decision closure, not a quantified business outcome. Already told on Thursday and never primary here: S/4HANA / ISM, Flexport estimation / FF App, Shipment Visibility, safety stock, the 200-lane program.

Manhattan Associates note. The master packet and GFiber v8 carry exactly two Manhattan stories, S13 (Cyber Monday allocation) and S14 (the OMS↔WMS discrepancy); both are allocated to Venkata and are not retold here. No other Manhattan process-improvement story exists in any source, so I do not invent one. What James gets is the Manhattan **configuration context** — Manhattan DOM/OMS is the only platform I personally configured (record) — carried as a one-paragraph bridge in section 7, mapped to his configuration-governance bullet.

Contents

1 · S17 — Elementum: the semi-annual carrier bid — a lane master and explicit constraint rules cut the cycle from about six weeks to about three (no award dollar claimed)

2 · S10 — Elementum: Austria — routing-guide data quality from about 55% true to about 99% within a quarter; the Finance-signed method before the number

3 · S15 — Sephora: change governance — a 20-person Product/Eng/QA team to a four-week cadence in six weeks; the gate owned by the skeptic

4 · A4 — Flexport: the Crux decommission — an apples-to-apples reliability lens (79 customers · $185,892 ARR documented base · 294,581 annual containers · about 27% vs 25% · 90% against an 80% north star)

5 · L22 — Flexport: Customs Platform vs FFA ownership resolved at work-item grain (15 work items, 12 export + 3 import; FFA all except ISF filing)

6 · G3 — Flexport: the security review I discovered instead of planned — FULL FAILURE STAR with three-level probes

7 · Manhattan configuration-context bridge · the one-line failure ledger across all six · 20-second versions on one page

1 · S17 — Elementum: the semi-annual carrier bid — a lane master and explicit constraint rules cut the cycle from about six weeks to about three LIVED RECORD

Company / role: Elementum, customer transportation team · I owned requirements, the constraint rules and the parallel run — not the award (Transportation and Procurement ran it).
LPs: Invent and Simplify (primary) · Dive Deep (the time audit) · Frugality · Earn Trust (the dollar I refused to claim).
Headline: carrier-bid cycle about six weeks → about three (record); pilot region finished three weeks early (record); back-test mismatch under 5% against the last two awards before the optimizer could run (record, the published gate). **No award dollar claimed.**
His bullet: policy platform migration (rules engine → explicit, reviewable rules) · pre-deployment validation (the back-test gate) · AI/tool-assisted configuration for non-specialists.

60-SECOND PITCH

SAY THIS, THEN STOP ON THE PRIMARY METRIC

Situation. The customer's transportation team ran a carrier bid twice a year: hundreds of lanes, dozens of carrier rate files, constraints like incumbency floors and volume commitments. Each cycle took about six weeks and everyone in the room called it an optimization problem. **Task.** I owned the requirements, the constraint rules and the parallel run — Transportation, Procurement and engineering did not report to me, and I never owned the award. **Action.** I sat through one full cycle logging hours, and the audit contradicted the room: the six weeks went to reconciling lane names and mode codes across carriers, not to analysis. So I wrote a lane master — one normalized origin, destination and mode key — and turned every tribal constraint into one explicit, written rule. I published a validation gate before any optimizer ran: the rules had to reproduce the last two real awards with under five percent mismatch, and every scenario had to be explainable in one sentence to an incumbent carrier. I rejected a black-box cheapest-lane solver in writing. Then I parallel-ran one region's real bid, tool against manual. **Result.** The pilot region finished three weeks early and the cycle went from about six weeks to about three; the other regions adopted the tool without a mandate because each region's own constraints lived in it as rules. I do not claim a dollar on the award — the people who ran the negotiation own that.

STAR — FIRST PERSON

S — Situation. Semi-annual carrier bid at an Elementum transportation customer: hundreds of lanes, dozens of rate files, constraints (volume commitments, incumbency floors, mode eligibility), about six weeks per cycle. Origin/destination naming and mode codes differed per carrier. The team, my sponsor and engineering all assumed the bottleneck was optimization.

T — Task. Own the requirements, the constraint rules and the parallel run; get a defensible award in less time without owning the award itself. No line authority over Transportation, Procurement or engineering.

A — Action. (1) *Discovery:* I sat one entire cycle and kept an hour log by activity; reconciliation dominated, analysis was the minority; I wrote the problem-class statement and got Transportation to agree the cost was reconciliation. (2) *Design:* I specified the lane master (origin / destination / mode normalization), wrote constraints one per rule, published the pre-run validation gate (under 5% mismatch against the last two awards), made scenario comparison a first-class output and rejected the black-box solver in writing. (3) *Build and test:* I held engineering to the spec, ran the back-test read-out where every mismatch against two historical awards was classified — naming, mode code, constraint semantics — with an owner, and required a stale-data banner past ten days. (4) *Pilot:* parallel run on one region's real bid; acceptance was the regional team's own judgment: the tool matched their defensible choices and beat cycle time; the manual process stayed alive as rollback. (5) *Adoption:* weekly rate-file refresh cadence; Procurement brought into the constraint definitions — late, which is my named miss.

R — Result.

- Cycle time about six weeks → about three, roughly half (record); pilot region finished three weeks early (record).
- Back-test mismatch under 5% against both prior awards before the optimizer was allowed to run (record — the published gate).
- Regions adopted without a mandate; constraint definitions now written with Procurement in the room (record).
- Analyst hours returned: modeled only, on illustrative analyst and region counts; I state the range and label it. No savings on the award — Transportation and Procurement ran it.

WHO I INFLUENCED, AND HOW

Transportation — by the hour log: I showed them where their own six weeks went, and they signed the rules. **Engineering** — they wanted a cheapest-lane solver; I made explainability the spec (scenario comparison first-class; under-5% back-test before any run). Objection became co-ownership of the gate. **Regional bid teams** — I made their judgment the acceptance test, so the pilot's result was theirs. **Procurement** — too late; "incumbency floor" meant different things to Transportation and the category manager, and I only learned that after design sign-off.

TRADE-OFF I MADE. Options: (a) a black-box cheapest-lane solver, fast to build; (b) a lane master plus explicit rules with a historical back-test gate, slower first cycle; (c) keep the manual process and add staff. I chose (b): a slower first cycle to write and validate the rules, for a tool that roughly halved every cycle after. I rejected (a) because an award nobody can explain in a carrier meeting does not survive the incumbent; I rejected (c) because the problem class was reconciliation, which staff does not fix. What it cost: one slower first cycle, and a dollar figure I will never be able to claim because the award was not mine.

Failure / learning. Procurement joined after design sign-off, and the constraint-semantics risk fired exactly where I had not put them in the room. Rule since: every function that owns a word in a rule is in discovery on day one.

LP TAGS

- **Invent and Simplify** — a time audit that contradicted the room, then one lane master and explicit rules beat the fancier solver.
- **Dive Deep** — I logged hours for a full cycle instead of interviewing; the data overturned the "optimization" belief.
- **Frugality** — simplification over a new solver; the manual process stayed as free rollback.
- **Earn Trust** — I refused the award dollar I could not defend, which is what makes the numbers I do defend credible.

SAFE-SAY. Most attackable number: "My program anchor is about six weeks to about three; I claim no award savings — Transportation and Procurement ran the award." Source question: "The cycle time, the pilot finishing three weeks early and the five-percent back-test gate are the record in my master packet; analyst counts, region counts and any dollar on hours are my model, labeled as such."

20-SECOND VERSION

"A six-week carrier bid everyone called an optimization problem turned out, when I logged the hours, to be a reconciliation problem. I wrote a lane master and explicit constraint rules, gated the optimizer on reproducing the last two awards within five percent, and parallel-ran one region. The cycle went to about three weeks and other regions adopted without a mandate. I claim no dollar on the award."

PROBES — ANSWER THE ONE ASKED, THEN STOP

Q1. Why does this count as process improvement rather than a tool build?

Because the artifact that mattered was the rule set and the gate, not the code. The lane master made the data configurable by non-specialists — a regional analyst could add a lane or a constraint as a row, not a ticket — and the back-test gate was a pre-deployment validation that stopped a bad configuration from reaching an award. Engineering built to that spec; the process was mine.

Q2. How did you validate the rules before anyone trusted the output?

Against two historical awards: the model's award had to match the actual award on more than 95% of lanes evaluated. Every mismatch was classified — naming, mode code, constraint semantics — with an owner, in one read-out. That is where most of the reconciliation logic got fixed, and the optimizer did not run below the bar.

Q3. What went wrong, and what did you change?

Procurement was not in discovery. "Incumbency floor" meant different things to Transportation and the category manager, and the rule carried only one meaning. I brought Procurement into the constraint definitions late, and for the next cycle they were in discovery on day one. The checklist change: a rule's words are owned by every function that uses them.

Q4. Surely the faster bid saved freight dollars?

Possibly, and that claim belongs to the people who ran the award. What I can defend is the cycle halving, the five-percent back-test and the analyst hours returned — the hours modeled and labeled. Refusing the dollar I cannot defend is what keeps the ones I do defend credible.

HOW THIS MAPS TO HIS BULLETS

Policy platform migration — tribal constraints became explicit, reviewable rules in one master (the same move as a legacy placement rules engine to a centralized policy platform). **Pre-deployment validation** — the under-5% back-test against real history is a change gate before anything reaches production. **AI-assisted / self-serve configuration** — the lane master let non-specialist regional analysts configure their own constraints as rows; the stale-data banner is the auditability control. **Point of contact** — Transportation, Procurement, engineering, regional teams.

2 · S10 — Elementum: Austria — "the noise said carriers; the data said measurement" — routing-guide data quality from about 55% true to about 99% within a quarter

LIVED RECORD

Company / role: Elementum, customer transportation (Austria site first, then 25 EU sites) · I owned the analysis and the rules design and pulled the data myself; the data-platform team built the engine; Finance signed the savings method.
LPs: Are Right, A Lot (primary) · Dive Deep · Earn Trust (Finance-signed method before the number) · Success and Scale Bring Broad Responsibility (one site's fix became 25 sites' instrument).
Headline: routing-guide data quality about 55% true (40% reported) → about 99% within a quarter (record); manual reconciliation 8–10 → 1–2 hours a week (record); $500K/yr at Austria on a Finance-signed, executed-only method, about $8M across 25 EU sites (record).
His bullet: post-incident corrective actions at the defect-class level · pre-deployment validation (the scorecard gate) · a rules engine with "no-hit pages a human, never a default" · governance SOPs (super-users, one-page runbook).

60-SECOND PITCH

SAY THIS, THEN STOP ON THE PRIMARY METRIC

Situation. Transportation at the customer's Austria site could not measure on-time delivery. The report said data quality was 40%, the team spent eight to ten hours a week reconciling promised against actual dates by hand, and everyone — the site, the carrier account teams, my own sponsor — believed the carriers were late. **Task.** I owned the analysis and the rules design. **Action.** I pulled three years of shipment history in SQL myself and ran a defect census: missing rates, wrong-grain lanes, five spellings of one carrier, brochure transit times posing as promises. True quality was about 55%, not 40%, and the problem was measurement, not carriers. I designed the promised-delivery-date as a routing-guide rules engine — lookup by ship-from, ship-to, mode, volume band, Incoterm and SLA, with a no-hit paging a human instead of defaulting a carrier. Before any dollar was claimed I had Finance sign the savings method: contracted guide rate minus paid rate, executed shipments only. I treated defects as classes with reason-code alerts and a weekly burn-down, and I would not release the carrier scorecard until automated on-time delivery matched a manual sample per lane cohort. **Result.** Data quality went from about 55% true to about 99% within a quarter; manual reconciliation fell from eight to ten hours a week to one or two; the carriers never disputed the scorecard. Austria delivered $500K a year on the signed method, and the same rules file plus one data-quality cycle per site rolled to 25 EU sites, about $8M.

STAR — FIRST PERSON

S — Situation. Austria site, freight base about $5M a year, no enforceable on-time delivery. Reported data quality 40% (a single-field proxy); 8–10 hours a week of manual reconciliation; a shared belief that carriers were the problem.

T — Task. Own the analysis and the rules design; produce an on-time measure the carriers could not dispute and a savings number Finance would stand behind.

A — Action. (1) *Discovery:* three years of history in SQL, pulled by me; defect census by class; true quality about 55%; sponsor accepted the reframe on the evidence. (2) *Design:* rules-engine spec with Incoterm in the key (about 8% of lanes needed it, because Incoterm changes who owns the clock); no-hit pages a human, never a default carrier; reason-code alert design; the Finance-signed savings method before any claim; a published scorecard gate — automated OTD must equal the manual sample per lane cohort. (3) *Build and test:* held engineering to the spec; weekly defect burn-down by reason code; manual-sample comparison per cohort. (4) *Cutover:* released the scorecard only after the gate passed; retired manual reconciliation; stood up the per-shipment savings ledger. (5)

Scale: super-user per region, a one-page runbook (add a lane · read a no-hit · when to escalate), two shadowed rule reviews per site, then site by site.

R — Result.

- Routing-guide data quality about 55% true → about 99% within a quarter (record).
- Manual reconciliation 8–10 → 1–2 hours a week per site (record); carriers did not dispute the scorecard (record).
- $500K/yr at Austria, 10% of a roughly $5M base, Finance-signed executed-only method (record); about $8M across 25 EU sites and 400+ lanes (record). Negotiated-but-not-executed never counted.
- Adoption cost per site: a rules file plus one data-quality cycle, measured in days (record).

WHO I INFLUENCED, AND HOW

My sponsor — wanted the scorecard fast and was unhappy for weeks; I showed defect classes trending down weekly and the manual-sample gate it had to pass. **Finance** — I asked them to sign the method before the number existed, which made every later dollar un-arguable. **Carrier account teams** — they had been blamed for our measurement error; a scorecard built on valid promises only was one they could accept. **Regional super-users** — I handed them the rules file, the runbook and two shadowed reviews, then stepped back.

TRADE-OFF I MADE. Options: (a) ship the scorecard on the data we had and fix later; (b) delay the scorecard weeks until automated OTD matched the manual sample per cohort; (c) buy a carrier-performance product. I chose (b) — I traded date for evidence and kept scope whole. I rejected (a) because a scorecard on 55% data would have been disputed and the carriers would have won; I rejected (c) because the defect was in our own lane and promise data, which no vendor fixes. What it cost: a sponsor unhappy for weeks and the manual process kept alive longer than anyone wanted.

Failure / learning. I proved the brochure transit times wrong lane by lane; starting from an industry transit benchmark would have reached the same answer faster. Rule since: measure before you blame, and sign the method before the number.

LP TAGS

- **Are Right, A Lot** — the room said carriers; three years of data said measurement, and I changed the decision on the evidence.
- **Dive Deep** — I pulled the data myself and classified every blank into a defect class before proposing anything.
- **Earn Trust** — Finance-signed, executed-only savings method before the first dollar was spoken.
- **Success and Scale Bring Broad Responsibility** — one site's fix became a 25-site instrument with a runbook and super-users, so it survived me.

SAFE-SAY. Most attackable number: "About $8M is the executed-only ledger across 25 sites on the method Finance signed before the first claim; the Austria $500K is that method's proof. I say eight million, never a smaller figure, and never anything merely negotiated." Source question: "The data-quality, hours and savings figures are record in my master packet; the analyst-capacity dollars are my model and I label them."

20-SECOND VERSION

"Austria could not measure on-time delivery and blamed the carriers. I pulled three years of data myself: true quality was about 55%, not the 40% reported, and the problem was our measurement. I designed the promised date as a rules engine, had Finance sign the savings method first, and gated the scorecard on matching a manual sample. Quality reached about 99% within a quarter; the fix rolled to 25 sites."

PROBES — ANSWER THE ONE ASKED, THEN STOP

Q1. How is this a configuration-governance story?

The routing guide is a rules engine; a no-hit paged a human rather than defaulting a carrier, which is the "no unintended deployment" principle. The scorecard had a pre-release gate (automated equals manual sample per cohort). And the post-incident loop was corrective action at the defect-class level — alerts by reason code, burned down weekly — not one-off fixes.

Q2. Why pull the data yourself instead of asking the team?

Because the room already had an explanation. Three years in SQL was faster than a request queue and could not be argued with. Once the sponsor saw every blank classified, the reframe held.

Q3. How did you make the rollout to 25 sites repeatable?

Each site cost a rules file and one data-quality cycle. A regional super-user ran the file after two shadowed rule reviews using a one-page runbook: add a lane, read a no-hit, when to escalate. That is a change-management SOP; adding a site took days.

Q4. What would you do differently?

Start with the industry benchmark for lane transit times instead of disproving the brochure lane by lane — same answer, weeks faster. And I would publish the scorecard gate on day one so the sponsor's impatience had a visible finish line.

HOW THIS MAPS TO HIS BULLETS

Post-incident corrective actions — defect classes with reason codes, weekly burn-down, the same metric proving the fix. **Pre-deployment validation** — the scorecard could not ship until automated matched manual per cohort. **Governance SOPs** — runbook, super-users, shadowed reviews; adoption cost measured. **Escape routing analog** — a no-hit pages a human, never a silent default. **Point of contact** — Transportation, Finance, carrier account teams, regional operations.

3 · S15 — Sephora: change governance — a 20-person Product/Engineering/QA team moved to a four-week cadence in six weeks, with the gate owned by the skeptic

LIVED RECORD

Company / role: Sephora, supply-chain technology · newly joined, VP air cover, no line authority over anyone in the room; the QA lead authored the definition-of-done — I coached the frame, she owned the gate.
LPs: Hire and Develop the Best (primary) · Insist on the Highest Standards (the gate) · Strive to be Earth's Best Employer (QA elevated, not blamed) · Earn Trust.
Headline: 20-person team converted from a six-week hybrid cadence to four-week agile in six weeks (record); critical defects per release down about 50% under the drop-date rule (record); the gate defended by its owner after I stepped back (record). Dollars are modeled only; no headcount invented.
His bullet: change-management SOPs (definition-of-done, entry criteria, drop date with reason codes) · auditability across many changes (Jira benefit-ranking and review-status fields) · fewer unintended deployments (nothing enters QA that does not meet entry criteria).

60-SECOND PITCH

SAY THIS, THEN STOP ON THE PRIMARY METRIC

Situation. Newly joined at Sephora, the VP of Supply Chain asked me to move a 20-person Product, Engineering and QA team from a six-week hybrid cadence to four-week agile. QA — a contracting firm — and in-house engineering were heading for a standoff: QA feared compressed test windows, and they were right. **Task.** Convert the cadence in weeks, not quarters, without the standoff becoming the story, and with no line authority over anyone in the room. **Action.** I did one-on-ones with every person and named an influencer per function. Then I made the most skeptical person — the QA lead — the author of the definition-of-done: I coached what a gate needs to say no and survive a release-day argument; she wrote the content. In Jira I added benefit-ranking and review-status fields so a story entered QA only when its entry criteria were met, and I put a QA drop date with reason codes on every sprint, so a heavy story landing in the last two days became a visible re-scope rather than a silent slide. I seated QA on the product-business calls with pre-approved scenarios, and I had Sev-1 causes classified so story-accuracy defects stopped being blamed on test. **Result.** The team was on a four-week cadence in six weeks; critical defects per release fell about half under the drop-date rule; and the QA lead defended the gate to engineering herself. I stepped back from the review line and neighbouring teams copied the ceremony from the user guide.

STAR — FIRST PERSON

S — Situation. 20-person Product/Engineering/QA team; six-week hybrid cadence; VP mandate for four-week agile; QA (contractor) versus engineering (in-house) standoff over the compressed test window — a legitimate fear.

T — Task. Convert in weeks with no rise in escaped criticals and the QA window protected by rule. VP sponsorship, no line authority.

A — Action. (1) *Discovery, weeks 1–2:* one-on-ones with everyone; objections heard privately; the QA lead agreed to author the gate before anything was scheduled. (2) *Design, weeks 2–3:* four-week ceremony calendar; definition-of-done frame (hers in content, mine in frame); Jira field spec; user-guide outline; engineering reviewed entry criteria — review, not veto. (3) *Build, weeks 3–5:* user guide from grooming to completion; live dashboard; QA drop date with reason codes; QA on product-business calls with pre-approved scenarios; Sev-1 cause classification. (4) *Cutover, week 6:* one facilitated retro; a data read-out to the VP; the gate handed to the QA lead to defend herself. (5) *Hypercare:* I left the review line; two cycles of stories meeting entry criteria and drop-date reasons trending to genuine re-scopes; neighbouring teams copied the ceremony.

R — Result.

- Four-week cadence live in six weeks (record); releases per year rise from about 8.7 to 13 (modeled from the cadence).
- Critical defects per release down about 50% under the drop-date rule (record; baseline count not in the record, so I do not quote one).
- The gate survived my leaving: the QA lead defended it to engineering without me (record).
- Dollars: about $130K/yr modeled on illustrative defect counts and benchmark costs; I say "modeled" every time.

WHO I INFLUENCED, AND HOW

The QA lead — by giving her the load-bearing artifact and the frame, not by writing it for her. **Engineering** — review rights on the entry criteria and cover from me for the low-impact stories they had to drop; objection became co-ownership. **The VP** — a data read-out, not a status; the rollback (revert to six weeks) named at kickoff as a two-way door and never used. **Neighbouring teams** — adoption by copying the user guide, without a mandate.

> **TRADE-OFF I MADE.** Options: (a) write the definition-of-done myself and impose it fast; (b) let the skeptic author it, slower by a week or two and riskier to the VP's timeline; (c) keep six weeks and add QA capacity. I chose (b). I rejected (a) because a gate I write dies when I leave; I rejected (c) because the mandate was cadence and the constraint was the window, not headcount. What it cost: low-impact stories dropped under the drop-date rule — dev's date protected, QA's window protected, and I covered some of those drops myself.

> **Failure / learning.** I went to engineering first and QA second. I should have gone to QA first and put the QA lead's name on the review line from week one; development that depends on me staying is not development.

LP TAGS

- **Hire and Develop the Best** — the skeptic authored and then defended the standard; I measured development by whether the gate survived my leaving.
- **Insist on the Highest Standards** — a gate that can say no, entry criteria per story type, drop date with reason codes.
- **Strive to be Earth's Best Employer** — QA moved from blamed afterthought to owner of the standard, with cause classification protecting them.
- **Earn Trust** — rollback named at kickoff; hard feedback sideways through the issues rows, and the evidence got overloaded people help.

> **SAFE-SAY.** Most attackable number: "Critical defects per release fell about half under the drop-date rule; the record gives me the percentage, not the base count, so I do not quote one." Source question: "The six weeks, the four-week cadence and the 50% are the record in my master packet; the dollars are my model on illustrative counts, and I did not invent a headcount."

> ### 20-SECOND VERSION
>
> "Asked to move a 20-person team from six-week to four-week cadence with no authority over anyone, I had the most skeptical person — the QA lead — author the definition-of-done, added entry-criteria fields in Jira and a drop date with reason codes. Converted in six weeks; critical defects per release fell about half; she defended the gate without me."

PROBES — ANSWER THE ONE ASKED, THEN STOP

> **Q1. This is a software-cadence story — why does it matter for configuration governance?**
>
> Because the mechanism is identical: nothing enters the next stage without meeting written entry criteria; every late change gets a reason code instead of a silent slide; the person with the most to lose owns the gate; and the same metric that found the problem proves the fix. Swap "story" for "network configuration change" and it is a change-management SOP with an audit trail.

Q2. Why hand the load-bearing artifact to the skeptic?

A gate the skeptic owns survives pressure; one I write dies when I leave. I coached the frame — what a gate needs to say no and survive a release-day argument — and she wrote the content. Engineering reviewed, did not veto.

Q3. Faster cadence usually means more escapes — why did yours fall?

Because the gate got stronger as the window got shorter. Entry criteria authored by the person with the most to lose, and a drop date that converted silent late lands into visible re-scopes. I count per year, not per release: halving per release at 13 releases still nets fewer escapes than the old cadence.

Q4. How did you know you could step back?

Two cycles of stories entering QA meeting their entry criteria, drop-date reasons trending toward genuine re-scopes, Sev-1 causes classified, and the QA lead defending the gate to engineering herself. Then I stopped attending the review line.

HOW THIS MAPS TO HIS BULLETS

Change-management SOPs — definition-of-done with entry criteria; drop date with reason codes; user guide from grooming to completion. **Auditability across hundreds of weekly changes** — Jira benefit-ranking and review-status fields make every change's state visible. **Fewer unintended deployments** — nothing crosses the gate without meeting criteria. **Training delivery** — the user guide neighbouring teams copied. **Point of contact** — Product, Engineering, QA, the VP.

4 · A4 — Flexport: the Crux decommission — an apples-to-apples reliability lens before retiring a legacy source (79 customers · $185,892 ARR documented base · 294,581 annual containers) LIVED RECORD · DOC-BACKED

Company / role: Flexport, 2021–22, visibility program · I owned the decommission risk, the comparison method and the one-canonical-source rule; engineering added sources; the transition-document owners built the per-customer paths with me.
LPs: Are Right, A Lot (primary) · Dive Deep · Ownership · Success and Scale Bring Broad Responsibility (retiring two truths deliberately).
Headline: normalized comparison about 27% versus our 25% (record); reliability 90% against an 80% north star after source work (record); legacy base 79 customers, $185,892 ARR, 294,581 annual containers, each with a per-segment path (record-from-docs, RAPID Crux transition). **The ARR is the documented legacy base, not a one-period loss.**
His bullet: policy platform migration (retire the legacy engine on evidence, one canonical definition) · post-incident corrective action (reconcile before compare) · Finance / Topology partnership (one scoreboard).
Different-angle rule: Rocky may hear Crux as program/cutover; Venkata as product/customer. James gets the analytics-and-governance lens only.

60-SECOND PITCH

SAY THIS, THEN STOP ON THE PRIMARY METRIC

Situation. At Flexport the biggest risk on the visibility program was decommissioning the legacy source — a parallel product still billing 79 customers and about $186K of annual recurring revenue, with defenders in the room — while leadership stared at our 25% schedule reliability against a competitor's 63%, a comparison run on unlike source mixes. Unmanaged, that ends in a write-off of the new product and a legacy that never retires. **Task.** I owned the mitigation: an honest comparison, the residual product gap exposed, and every legacy customer given a destination instead of letting the decommission drift another cycle. **Action.** I put the decommission at the top of the risk register with an owner, plan and date. I rebuilt the comparison instead of arguing it — normalized both products to the same sources, and the competitor's 63% re-scored to about 27% against our 25%: a measurement gap, not a product gap. The same normalization also exposed the real gap, variance of sixteen days against their eight, which I named myself and handed to the source-addition backlog with six months to close. I segmented all 79 legacy customers into migrate, white-label or cancel so keeping both products carried a visible weekly cost, wrote the one-canonical-source rule — one definition of reliability, one scoreboard — and made one forum sign the improvement plan and the retirement plan in the same week. **Result.** The decommission went through on evidence: 79 customers and 294,581 containers a year, each with a path; reliability climbed to 90% against an 80% north star once sources were added; and the norm that survived was that two numbers that disagree get reconciled before they get compared.

STAR — FIRST PERSON

S — Situation. New visibility product judged at 25% schedule reliability against a competitor's 63%, on unlike source mixes. Legacy source still billing 79 customers / $185,892 ARR (record-from-docs). Two dashboards, two truths, each with a constituency.

T — Task. Own the retirement risk: establish an honest comparison, expose any residual product gap, give every legacy customer an explicit path and date.

A — Action. (1) Risk register: decommission as top risk with owner, mitigation, date. (2) Rebuilt the benchmark on identical sources — 63% re-scored to about 27% vs 25%; gave the old dashboard's defenders a dignified retirement (their number was valid on its own basis; I changed the basis, not the team). (3) Named the unfavorable residual — variance sixteen days vs eight — and secured six months of source additions. (4) Segmented all 79

customers (enterprise and mid-market → new product; carriers and brokers → white-label or cancel; SaaS lookalikes → cancel) with a destination and date each. (5) Wrote the one-canonical-source rule and ran one forum that signed improvement and retirement together.

R — Result.

- Normalized comparison about 27% vs 25% — measurement, not product, was the immediate gap (record).
- Reliability 90% against an 80% north star after source work (record) — real work, not normalized math.
- 79 customers, 294,581 annual containers, $185,892 ARR documented base — every customer with a per-segment disposition (record-from-docs).
- Durable mechanism: one definition, one scoreboard; reconcile before compare (record).

WHO I INFLUENCED, AND HOW

Leadership — by changing the basis of the comparison in front of them, not by defending the number. **The team whose dashboard had won the old comparison** — their figure was cited as the prompt for the source work, never mocked as the loser; people accept a new canonical source when the old one is buried with honors. **Engineering** — got a named residual (variance) and six months, rather than an argument. **Transition-document owners** — built the per-customer paths with me under one forum.

TRADE-OFF I MADE. Options: (a) add sources first and skip the comparison fight — quarters of work while a write-off takes one meeting; (b) normalize first to earn the time, then improve to deserve it; (c) keep both products and both dashboards. I chose (b). I rejected (a) on sequence — the decision was already on the table; I rejected (c) because running two truths cost ops and engineering more every week than the revenue was worth. The deliberate cost: $185,892 of legacy ARR retired on purpose, and six months of patience before the honest 90%.

Failure / learning. I should have written the one-canonical-source rule before the first executive comparison, not after the first bad one. Once dashboards have constituencies, a cheap definition becomes an expensive negotiation.

LP TAGS

- **Are Right, A Lot** — I changed the decision by making both products use the same evidence, and the normalization cut both ways.
- **Dive Deep** — I exposed the sixteen-versus-eight-day variance residual instead of using normalization only to flatter us.
- **Ownership** — every one of 79 customers received a destination and a date; the decommission stopped drifting.
- **Success and Scale Bring Broad Responsibility** — retired two truths deliberately so a hundred teams stop arguing about whose number is real.

SAFE-SAY. Most attackable number: "The transition document records 79 customers, $185,892 of annual recurring revenue and 294,581 annual containers — that ARR is the documented legacy base, not a claim that we lost it in one period. The 90% is the workbook record; the normalized comparison is about 27% versus 25%." Source question: "The Crux customer-transition RAPID and my 2022 product-management record, reconciled in my Apple workbook chapter A4."

20-SECOND VERSION

"Leadership was comparing our 25% reliability with a competitor's 63% on unlike source mixes while a legacy product still billed 79 customers. I normalized both to one basis — the competitor re-scored to about 27% — named the real gap, gave all 79 customers a path, and retired the duplicate truth while reliability rose to 90% against an 80% north star."

PROBES — ANSWER THE ONE ASKED, THEN STOP

Q1. Wasn't the normalization just spin?

It cut both ways, which is why it was credible. It removed the false 63-versus-25 alarm, and it exposed the unfavorable variance — sixteen days against their eight — which I named myself and handed to the backlog. A normalization that only flatters is spin; one that also exposes is analysis.

Q2. Why does retiring about $186K of ARR matter — that is small revenue?

Because the revenue was small and the drag was not: every week both products ran, ops and engineering paid for two truths and prospects compared us against ourselves. The transition document priced all 79 customers by segment. Retiring small revenue deliberately is harder than growing big revenue, and it was planned, not drifted into.

Q3. What was yours versus the team's?

I rebuilt the comparison, wrote the one-source rule, priced the legacy base per segment and made the sequence call — normalize to earn the time, improve to deserve it. Engineering added the sources; the transition-document owners built the per-customer paths with me.

Q4. How would this travel to a placement-policy migration?

Anywhere two engines disagree — legacy rules versus new policy — I would reconcile the definitions before anyone compares outputs, run one scoreboard, give every legacy rule or node a disposition and date, and have one forum sign the improvement plan and the retirement plan together. The rule outlives the slide.

HOW THIS MAPS TO HIS BULLETS

Policy platform migration — retiring a legacy engine on evidence with every legacy customer (read: rule, lane or node) given a destination and a date. **Post-incident corrective action** — the one-canonical-source rule as the structural fix, not a one-off re-score. **Point of contact with Finance / Network Topology** — one definition, one scoreboard that both sides read the same day. **Governance** — one forum signs improvement and retirement together.

5 · L22 — Flexport: Customs Platform versus Freight Forwarding Applications — ownership resolved at work-item grain (15 work items: 12 export + 3 import; FFA all except ISF filing) LIVED RECORD · DOC-BACKED

Company / role: Flexport, 2022 · I created the decision artifact and drove convergence; neither team reported to me; the accountable engineering leaders signed the ownership agreement (Nov 3, 2022).
LPs: Ownership (primary) · Earn Trust · Invent and Simplify · Have Backbone; Disagree and Commit.
Headline: 15 planned 2023 work items — 12 export, 3 import — mapped row by row to one ownership agreement; final boundary: FFA owns all work items except ISF filing; AMS via Customs APIs (create, amend, query, delete); shared cost-to-serve goals where the seam remained (record-from-docs). **The documented result is decision closure and explicit interfaces, not a quantified business outcome.**
His bullet: placement-architecture point of contact across organizations · inbound/outbound connectivity contracts (who plans, who executes, which API, where status returns) · governance SOPs (named interim owner for every seam).

60-SECOND PITCH

SAY THIS, THEN STOP ON THE PRIMARY METRIC

Situation. In 2022 Flexport's Customs Platform and Freight Forwarding Applications teams overlapped on customs-declaration work, especially the automated manifest system. The 2023 roadmap carried fifteen work items — twelve export, three import — and ambiguous ownership meant duplicate builds, dependency queues and inconsistent status for operators. **Task.** Produce a durable boundary that let each organization stay in its domain while preserving one end-to-end operator flow. Neither team reported to me, and "Customs owns customs" was too vague to configure. **Action.** I stopped arguing about organizations and decomposed the roadmap work item by work item. Beside each I wrote the operating decision: who plans, who executes, who owns the backend and data model, which actions stay offline, what API is required, and where status returns. I separated customs-domain planning and filing from FFA's operational execution of moving cargo. For the disputed seams — EAD, port filing, ISF, AMS — I documented current capability, future capability and an interim owner instead of pretending the target architecture already existed; a future capability never erased the named interim owner. I used the same sheet in the final cross-team meeting and captured the unresolved rows explicitly. **Result.** The November 3 ownership agreement assigned FFA all work items except ISF filing; AMS used Customs APIs for create, amend, query and delete; ISF kept a query dependency; AES aligned on integration; and where the seam remained, both teams shared cost-to-serve goals. The roadmap had one accountable owner per row and an explicit interface wherever ownership crossed an organizational line.

STAR — FIRST PERSON

S — Situation. Two tech organizations, one customs-declaration domain, fifteen 2023 work items (12 export, 3 import). Duplicate work and dependency queues were the default outcome.

T — Task. One boundary both leaders could sign; each team in its domain; one operator flow preserved. No authority over either team.

A — Action. (1) Reframed from organization grain to work-item and state-transition grain. (2) For every work item: user group, description, exists-in-core, proposed owner, notes, engineering conclusion — the decision written beside the row. (3) Separated customs planning and filing from operational execution of cargo. (4) Disputed seams got current capability, future capability, interim owner; AES filing explicitly parked as "need more time" rather than forced. (5) Ran the final meeting off the same sheet; captured open rows; tied shared seams to shared cost-to-serve goals.

R — Result.

- Ownership agreement, Nov 3 2022: FFA owns all work items except ISF filing (record-from-docs, proposal p.14).
- AMS: Customs API for filing-request creation, amendment, query and deletion; AMS broadcasts filing status (record-from-docs).
- ISF: Customs owns filing; FFA retains API query for status; AES aligned on API integration; import work items API-only (record-from-docs).
- One accountable owner per row and an explicit interface at every cross-organization seam. No defect or cycle-time claim — the source does not report one.

WHO I INFLUENCED, AND HOW

Two engineering leaders — by giving them a row-level artifact where disagreement had a specific address instead of a slogan; they signed. **Operations engineering** — the "where does this work item live" questions were routed to them explicitly rather than assumed. **Operators** — the design criterion throughout was one end-to-end flow with status returning to the place they worked.

> **TRADE-OFF I MADE.** Options: (a) wait for a clean platform split before assigning anything; (b) a pragmatic interim boundary with some offline work and API dependencies to govern; (c) a top-down ruling by organization. I chose (b). I rejected (a) because delivery would have stalled behind architecture; I rejected (c) because "Customs owns customs" cannot be configured and would have re-opened every sprint. What it cost: API dependencies on Customs Tech that FFA still had to manage, and a few rows parked as explicitly unresolved.

> **Failure / learning.** My first framing was organization-based and too abstract, and it went nowhere. The agreement emerged only after I moved to work-item and state-transition grain. Rule since: boundaries are configured at the grain where work actually changes hands.

LP TAGS

- **Ownership** — I took the seam no organization could solve alone and carried it to a signed agreement.
- **Earn Trust** — capability gaps and unresolved rows stayed visible in the artifact rather than being smoothed over.
- **Invent and Simplify** — one row-level matrix replaced a domain argument.
- **Have Backbone; Disagree and Commit** — I pushed back on the slogan framing, then committed to the interim boundary the leaders signed.

> **SAFE-SAY.** Most attackable claim: "The proposal states fifteen 2023 work items — twelve export and three import. The final agreement says FFA owned all except ISF filing; it does not claim a quantified business outcome, and neither do I." Source question: "The Customs Platform / FFA Ownership Proposal, pages 1 and 14, including the November 3, 2022 agreement."

> ### 20-SECOND VERSION
>
> "Two tech organizations overlapped on fifteen customs work items. I turned the argument into a row-by-row ownership proposal — who plans, who executes, which API, where status returns — with an interim owner for every disputed seam. The final meeting assigned FFA everything except ISF filing, with explicit APIs and shared cost-to-serve goals where the seam remained."

PROBES — ANSWER THE ONE ASKED, THEN STOP

> **Q1. Did you decide the boundary yourself?**
>
> No. I created the decision artifact and drove convergence; the accountable leaders signed the ownership agreement. My authority was the quality of the sheet.

Q2. How do you know it worked?

The documented result is decision closure and explicit interfaces — one owner per row, an API at every seam. I would not invent a defect or cycle-time reduction that the source does not report.

Q3. What did you do with rows nobody would own?

Parked them explicitly — AES filing was recorded as "need more time to resolve," with the preferred future state (API integration) and the current operator path both written down. An unresolved row that is visible is governance; one that is hidden is a future incident.

Q4. How does this translate to being the placement-architecture point of contact?

Same artifact: for every connectivity or routing change, who decides the policy, who executes, who owns the data model, which interface carries it, and where the status comes back — with Transportation, Finance, Topology and Operations each owning the rows that are theirs and a named interim owner wherever the target architecture is not built yet.

HOW THIS MAPS TO HIS BULLETS

Point of contact across Transportation, Finance, Network Topology, Operations — a row-level ownership matrix across organizations. **Inbound/outbound connectivity** — explicit API contracts (create, amend, query, delete; status broadcast) at every seam. **Governance SOPs** — named interim owner; unresolved rows captured, not hidden. **Crossdock / escape routing analog** — the operator flow is preserved end to end even when ownership changes hands mid-process.

6 · G3 — Flexport: the security review I discovered instead of planned — the full FAILURE story FAILURE · LIVED RECORD

Company / role: Flexport · the Snowflake pipeline that automated my manual four-system weekly business review (Apple workbook A3 / master S16 family) · I owned the BRD and the cutover; the infrastructure team owned the build.
LPs: Earn Trust (owned upward the same day) · Are Right, A Lot (the learning) · Dive Deep (root cause: scoping, not "slow security") · Ownership.
Headline: the customer-content data-access review was absent from my BRD and surfaced mid-build; it cost two weeks of schedule margin (record). No weekly review was skipped; cutover still waited for manual and automated metrics to agree within one percent for consecutive weeks; system accuracy closed at 90% from a 60% baseline (record). **The miss cost margin, not delivery.**
His bullet: pre-deployment validation (approval lead time is a gate, not a formality) · post-incident corrective action (the kickoff checklist changed permanently) · change-management SOP (keep the old path alive until the new one clears access and correctness).
Freshness note: S16's pipeline is the same program family as Shipment Visibility, told Thursday. Here it appears only as the failure, with the process lesson as the point — never as the pipeline achievement story.

60-SECOND PITCH

SAY THIS, THEN STOP ON THE PRIMARY METRIC

Situation. At Flexport I was replacing a manual, four-system weekly business review with a Snowflake pipeline. One source was ticket data carrying customer content. I had planned the extracts, the loads, the metric parity and the parallel-run cutover gate. I had not planned the data-access security review. **Task.** I owned the BRD and the cutover; when the review surfaced mid-build I had to complete it without skipping a single Monday operating review and without weakening the one-percent parity gate. **Action.** I owned the miss upward the same day as a scoping failure — the BRD had priced the build and never the review — not as "security is slow." The root cause was that I had treated approval as a formality instead of a workstream with lead time; customer content makes it a gate. I re-sequenced rather than bypass: the manual path stayed live during the parallel run, so the Monday review continued. I closed the review properly — cross-reference table documented, data classes named, read access made explicit. Then I changed the kickoff checklist permanently: security has an owner and a lead time in the BRD, and every data program since starts with "whose approval does this data need, and how long does that take?" **Result.** The access review cost two weeks of margin; no weekly review was skipped; the pipeline cut over only after manual and automated metrics agreed within one percent for consecutive weeks, and accuracy closed at 90% from a 60% baseline. The miss cost margin, not delivery — and the scar is the useful part.

STAR — FIRST PERSON

S — Situation. Snowflake pipeline replacing a manual four-system Monday review; ticket data with customer content in scope; BRD covered extracts, loads, parity, cutover gate — and not the data-access security review (record).

T — Task. Complete the review, keep every Monday review alive, keep the one-percent parity gate intact.

A — Action. (1) Owned it upward immediately as my scoping miss. (2) First principles: the noise said "security is slow"; the cause was that I had not treated approval as a lead-time workstream. (3) Re-sequenced: parallel run kept the manual path live, so the program absorbed two weeks without skipping delivery. (4) Closed the review properly: cross-reference table, named data classes, explicit read access. (5) Corrective action: a standing security line with owner and lead time in every BRD; the kickoff question on approval and lead time.

R — Result.

- Two weeks of schedule margin lost (record) — the failure.
- Zero skipped review weeks; cutover on the one-percent parallel-run gate for consecutive weeks (record).
- System accuracy 60% → 90% (record). Late on the review, on target everywhere else.
- A permanent checklist change that has since applied to every data program I have run (record).

WHO I INFLUENCED, AND HOW

My leadership — I framed the slip as my scoping failure before anyone else framed it as the security team's slowness; that is why the conversation stayed on the fix. **The security reviewers** — got a complete artifact (data classes, cross-reference, access model) instead of a request for an exception. **The infrastructure team** — were kept out of the blame; the BRD was mine.

> **TRADE-OFF I MADE.** Options: (a) ask for an access exception and cut over on schedule; (b) keep the labor-intensive manual path alive and absorb the two weeks; (c) pause the program until the review cleared. I chose (b). I rejected (a) because customer-content access was a gate, and bypassing it would have converted a schedule miss into a trust and compliance risk; I rejected (c) because the Monday review had to keep running. What it cost: two more weeks of my own time running the manual stitch, and two weeks of margin I never got back.

> **Failure / learning.** The parallel run saved me partly by luck — I had designed it as a correctness gate, not a schedule buffer. Now I plan that resilience deliberately: the old path stays alive until the new path clears both access and correctness. And: planned, not discovered.

LP TAGS

- **Earn Trust** — owned upward the same day, as my scoping failure, before anyone framed it differently.
- **Are Right, A Lot** — I changed how I scope every data program: approval lead time is a workstream with an owner.
- **Dive Deep** — the cause was structural (approval treated as a formality), not situational; that is why it earned a post-mortem.
- **Ownership** — I kept the manual path running myself rather than ask for an exception.

> **SAFE-SAY.** Most attackable claim: "I under-planned the customer-data access review by two weeks; the manual path kept every Monday review alive, and cutover still waited for one-percent parity." Source question: "My Apple workbook, chapter G3 and A3; the two-week miss and the parity gate are record, not modeled."

> **20-SECOND VERSION**
>
> "I discovered a customer-data security review mid-build and lost two weeks because it was absent from my BRD. I owned it upward as a scoping miss, kept the manual path alive so no weekly review was skipped, and cut over only on one-percent parity. Security lead time is now planned at kickoff, never discovered."

PROBES — THREE LEVELS; ANSWER THE ONE ASKED, THEN STOP

Level 1 — the facts

> **Q1. Two weeks is small — why call it a failure?**
>
> Because the cause was structural, not situational. Any data program touching customer content needs an access review, and I had not planned one — so without a checklist change I would have repeated it on every future program. Small miss, systemic cause; those are the ones worth a post-mortem.

> **Q2. Why not ask for an exception and hold the date?**
>
> Customer-content access was a gate. Bypassing it would have turned a schedule miss into a trust and compliance risk — the kind of unintended deployment a governance process exists to stop. I spent margin instead.

Level 2 — the mechanism

Q3. Why did the parallel run save you — was that design or luck?

Both, and I say so. I built it as a correctness gate — manual versus pipeline within one percent — and it happened to double as a schedule buffer. The honest admission is that I got resilience I had not planned. Now I plan it: the old path stays alive until the new path clears both access and correctness.

Q4. What does "planned, not discovered" look like in practice now?

A named line in the plan with an owner and a lead time, priced in the BRD next to the build cost, and a kickoff question — whose approval does this data need and how long does it take. In a later independent build I ran, access boundaries and citation discipline were designed in on day one rather than retrofitted.

Level 3 — the person

Q5. What did this reveal about how you scope, and has it recurred?

It revealed that I scoped what I could build and under-scoped what I had to be permitted to do. It has not recurred on a data program since, because the checklist forces the question before the build is priced. I would rather carry that scar visibly than claim I never had it.

Q6. How would this failure show up in configuration governance at Amazon?

Pre-deployment validation must include approvals and their lead times, not just technical checks; the old configuration path stays live until the new one clears both; and every post-incident corrective action should change a checklist, not just fix the incident. That is exactly the shape of the control this miss left me with.

HOW THIS MAPS TO HIS BULLETS

Pre-deployment validation — approval lead time is part of the gate. **Post-incident corrective actions** — the kickoff checklist changed permanently; the same KPI that found the miss proved the fix. **Change-management SOP** — keep the prior path alive until access and correctness both clear. **Fewer unintended deployments** — I refused the exception that would have deployed customer-content access without review.

7 · Manhattan configuration-context bridge · the failure ledger across all six · 20-second versions on one page

MANHATTAN ASSOCIATES — CONFIGURATION-CONTEXT BRIDGE (NOT A FULL STORY)

WHY THERE IS NO ADDITIONAL MANHATTAN STORY, AND WHAT TO SAY INSTEAD

The master packet and GFiber v8 contain exactly two Manhattan Associates stories — S13 (Cyber Monday 4 AM allocation across three DCs and about a hundred stores) and S14 (the OMS↔WMS discrepancy) — and both are allocated to Venkata. No other Manhattan process-improvement story exists in any source, so none is written here. The verified Manhattan fact that belongs to James is the configuration context: **Manhattan DOM/OMS is the only platform I have personally configured** (record). One-paragraph bridge, if he asks where my hands-on configuration experience comes from:

"My hands-on configuration years were on Manhattan's distribution order management suite — allocation and promising rules across three DCs and about a hundred stores. That is where I learned that a rule change is a deployment: it changes where units go the next morning. Everything since — the lane master at Elementum, the routing-guide rules engine, the definition-of-done at Sephora — has been about putting a validation gate and an owner in front of that kind of change. The two Manhattan stories I tell in full are allocated to another interviewer today, so I will not repeat them here unless you want one."

Guardrail: never claim Manhattan process-improvement numbers that are not in S13/S14; never say "I configured SAP." Manhattan DOM is the only first-hand platform-configuration claim in canon.

THE ONE-LINE FAILURE / LEARNING LEDGER — ONE PER STORY, FOR "TELL ME ABOUT ANOTHER TIME"

STORY	WHAT WENT WRONG, MY PART	WHAT CHANGED
S17	Procurement joined after design sign-off; "incumbency floor" meant two things.	Every function that owns a word in a rule is in discovery on day one.
S10	I disproved brochure transit times lane by lane — slow.	Start from an industry benchmark; measure before you blame; sign the method before the number.
S15	I went to engineering first, QA second.	Go to the skeptic first; put her name on the review line from week one.
A4	The one-canonical-source rule came after the first bad executive comparison.	Write the definition before dashboards have constituencies.
L22	My first framing was organization-based and too abstract.	Configure boundaries at the grain where work changes hands.
G3	Security review absent from the BRD; two weeks of margin lost (the full failure).	Approval lead time planned, not discovered; old path alive until access and correctness clear.

20-SECOND VERSIONS — ONE PAGE, IN SPEAKING ORDER

STORY	HEADLINE (BASIS)	SAY
S17	about 6 → about 3 weeks (record); no award $	A six-week bid everyone called optimization was reconciliation when I logged the hours; lane master, explicit rules, under-5% back-test gate, one-region parallel run; about three weeks; adopted without a mandate.
S10	about 55% → about 99% within a quarter (record)	Austria blamed carriers; three years of data said measurement. Rules engine, Finance-signed method first, scorecard gated on a manual sample; rolled to 25 sites.

STORY	HEADLINE (BASIS)	SAY
S15	20 people, 4-week cadence in 6 weeks; criticals about −50% (record)	The skeptic authored the definition-of-done; entry-criteria fields and a drop date with reason codes; she defended the gate without me.
A4	about 27% vs 25%; 90% vs 80% north star (record); 79 customers / $185,892 ARR base / 294,581 containers (docs)	Normalized an unlike comparison, named the real gap, gave all 79 customers a path, retired the duplicate truth.
L22	15 work items, 12 export + 3 import; FFA all except ISF (docs)	Turned an organization argument into a row-level ownership matrix with an interim owner per seam; leaders signed.
G3	2 weeks of margin lost; 1% parity held; 60% → 90% (record)	Discovered a customer-data access review mid-build; owned it upward; kept the manual path alive; planned, not discovered, ever since.

VERIFY ITEMS IN THIS FILE

- **S17** — no VERIFY on the record figures; analyst-hours dollars are modeled. Safe sentence: "My program anchor is about six weeks to about three; I claim no award savings."
- **A4** — the ARR is the documented legacy base, not a one-period loss; say it that way every time.
- **L22** — no quantified outcome exists in the source; say "decision closure and explicit interfaces," never a defect or cycle-time number.
- **Manhattan** — no process-improvement story beyond S13/S14 exists in any source; use the configuration-context bridge only.

Part 4C — James Cabreros (11:00 slot; schedule listed Zhaowen Lan) — Stories C

Scope: release governance and legacy-engine migration (design cases on lived record), AI-assisted configuration tooling, policy-platform sequencing, LP router, questions to ask

Friday, October 30, 2026 · Amazon L6 Senior Supply Chain Manager, NACF Supply Chain · Rajesh Rishiyur Chandrasekaran

Contents

1. J5 · E8 — Monthly release / regression governance (DESIGN CASE) on the lived S15 four-week cadence DESIGN CASE
2. J7 · E9 — Migrating a legacy rules engine without unintended deployments (DESIGN CASE) on the lived S18 RP→JDA cutover DESIGN CASE
3. AI-assisted configuration tooling — one page (I1: guardrails and operator self-service angle) NEW
4. Legacy rules engine → policy platform: how I would sequence it — one page DESIGN
5. Router for James — 16 LPs and process prompts → exact story pointers (real AIQB wordings)
6. Questions to ask James · source trace · VERIFY list with safe sentences

Rules for this part. E8 and E9 are **DESIGN CASES** from my interview-prep design engagement — I say "I designed / here is how I would run it," never "I delivered." Every design case is paired with a lived program I can be probed on (S15, S18, UDC B3, A4, I1). Basis labels: **record** (resume / Apple v11 / master canon) · **record-from-docs** (a page of a source document) · **design** (my proposed mechanism) · **illustrative**. Angle rule: Rocky hears the S18 and UDC programs as program/cutover; James hears them as process, configuration governance and validation. Already told Thursday (never primary here): S/4HANA / ISM, Flexport estimation, Shipment Visibility, safety stock, the 200-lane program.

1. J5 · E8 — Release and regression governance: how a change earns its way to production DESIGN CASE

DESIGN CASE + LIVED RECORD. The monthly SAP + integrations release train (E8) is a design I wrote in an interview-prep engagement; volumes illustrative. The record under it is lived: **S15** — the Sephora 20-person Product/Engineering/QA team moved from a six-week hybrid cadence to four weeks in six weeks, QA authored the release gate, critical defects −50% (record: resume; master S15). Sephora UDC facts used here are record: hard peak change-freeze October–December; anything touching the frozen spec went through the gate with an estimate; hypercare exited into the monthly release train (record: Apple v11 B1 p. 21–22; GFiber v8 S2).

His bullet it answers: "configuration governance — pre-deployment validation, change-management SOPs, post-incident corrective actions; fewer unintended deployments; auditability across hundreds of weekly changes."
LPs: Insist on the Highest Standards · Hire and Develop the Best · Earn Trust · Invent and Simplify |
Headline: four-week cadence in six weeks; critical defects per release −50% (record).

60-SECOND PITCH

"At Sephora the VP asked me to move a 20-person Product, Engineering and QA team from a six-week hybrid cadence to four weeks. QA feared compressed test windows, and they were right. I had no line authority, so I made the skeptic the owner: the QA lead wrote the definition of done, I coached the frame, and we added a QA drop date with reason codes so late, heavy stories were dropped on the record instead of squeezing the test window. Four-week cadence live in six weeks; critical defects per release down 50%; neighbouring teams copied the model. Later I designed the same mechanism as a monthly release train for SAP plus integrations: scope frozen at T-minus-15, regression cells owned at the true grain, a go/no-go the QA lead owns with blocker-plus-critical at zero, rollback per transport group, and hypercare that exits on a number. The principle for your world is the same: a change rides the gate or it does not ship, and every emergency change is counted."

S — Situation. *Lived (S15, record).* Newly joined at Sephora, the VP of Supply Chain asked me to convert a 20-person Product/Engineering/QA team from a six-week hybrid cadence to four-week agile. QA (a contracting firm) and in-house engineering were heading for a standoff: QA feared compressed test windows, and the Sev-1 trend was partly from story-accuracy defects. *Design case (E8, design).* The prompt: SAP configuration, custom objects, integration maps, the CRM, the 3PL interface and the field app all change; last month a release broke MRP. Design a train so changes ship monthly with no surprise on the floor.

T — Task. Convert the cadence in weeks, not quarters, with VP air cover and no line authority over anyone in the room — and keep escaped criticals from rising. In the design: one book of record for change (the transport/change log and the release manifest) and one primary metric — release-caused Sev 1–2 incidents per release driven to zero with the cadence held.

A — Action. What I did (lived), then what I designed on top of it.

- **Discovery (lived).** One-on-ones with every person; an influencer per function; the problem statement written as "QA's fear of compressed windows is correct." Exit: every real objection heard privately; the QA lead agreed to author the gate.
- **Gate ownership (lived).** The QA lead wrote the definition of done — entry criteria per story type at the Ready-for-QA transition. Engineering got review, not veto, and shaped the entry criteria. I wrote the success criteria with the VP: four-week cadence, no rise in escaped criticals, QA window protected by rule.
- **Risk-scoped intake (lived).** Jira fields for benefit ranking and review status; a QA drop date with reason codes so a late heavy story was re-scoped on the record; QA seated on product-business calls with pre-approved scenarios; Sev-1 causes classified.
- **Freeze and change control (lived, Sephora UDC).** Hard peak change-freeze October–December; anything touching the frozen spec went through the gate with an estimate, never absorbed quietly; after hypercare the design was handed into the monthly release train.
- **The train (design, E8).** Commit and freeze at T−15 (definition of ready cites a regression cell) → promote to integrated QA at T−10, imported in production sequence → regression matrix plus end-to-end chain at T−5 → go/no-go at T−2, QA lead owns it: Blocker + Critical open = 0, rollback plan per transport group, freeze check → deploy → hypercare with a numeric exit. Release notes and the go/no-go record are the audit artifacts.
- **Regression scope by risk (design).** Cells at the true grain (order type × fulfillment path × node × stock-state transition; interface round-trips per partner); an MRP-protection cell that diffs exception counts and planned-order totals by plant before vs. after the transport — an unexplained delta fails the build. Build the manual matrix first; automate the cells that fail most.
- **Corrective action (design).** Emergency changes are allowed, counted in the postmortem and 100% retrofitted into the train; configuration and code ride separate transports so a config rollback never drags code.

R — Result.

- Four-week cadence live in six weeks for a 20-person Product/Engineering/QA team `record`.

- Critical defects per release −50% under the drop-date rule record ; the QA lead defended the gate to engineering without me; neighbouring teams copied the ceremony from the user guide record .
- Rollback (revert to six weeks) named at kickoff as a two-way door; never used record .
- E8 target design metric: release-caused Sev 1–2 per release → 0, twelve trains a year with no skipped month, emergency changes ≤ 1 per release and 100% retrofitted design — a target, not a result.

TRADE-OFF I MADE. Options: keep six weeks; go to four weeks and absorb late stories; or go to four weeks with a drop-date rule. I chose the rule and dropped low-impact stories on the record — engineering's date protected, QA's window protected — and covered some of the drops myself. Cost: visible scope loss each cycle. In the design, a four-week train delays small fixes; I accept that and keep a counted emergency path rather than let urgency become a side door.

FAILURE / LEARNING. Development that depends on me staying is not development: the gate became durable only when its owner, not I, defended it. Hard feedback that I routed sideways through issues-log rows turned out partly to be genuine overload, and the evidence got those people help — I now check load before I treat pushback as resistance record: master S15 probes .

Insist on the Highest Standards — the gate could say no and survive a release-day argument; criticals −50%.
Hire and Develop the Best — I handed the load-bearing artifact to the skeptic and coached her to own it.
Earn Trust — I said publicly that QA's fear was correct before asking for a faster cadence.
Invent and Simplify — a drop date with reason codes replaced a last-two-days bug bash.

SAFE-SAY. "The six-week conversion and the 50% cut in critical defects are my record at Sephora; the dated monthly train with T-minus-15 and the MRP diff cell is a design I wrote from that experience, not something I claim to have run at that scale." **If asked for source:** "My resume line on the VP-sponsored conversion, and the master story record S15; the train is design case E8."

20-SECOND VERSION

"I moved a 20-person Product, Engineering and QA team to a four-week cadence in six weeks by making the QA lead the owner of the release gate and adding a drop date with reason codes. Critical defects fell 50%. I later designed the same gate as a monthly SAP release train: frozen scope, risk-scoped regression cells, a numeric go/no-go and counted emergency changes."

PROBES JAMES IS LIKELY TO ASK

1. You run hundreds of configuration changes a week, not a monthly train. What carries over?

The gate, not the calendar. I would classify changes by blast radius: low-risk rows go self-serve with automated validation and an audit row; high-risk rows (new node types, escape routes, capacity signals) ride a scheduled window with a go/no-go and a named rollback. The invariant is the same as at Sephora: nothing deploys that is not on the manifest, and every exception is counted. design

2. How did you scope regression by risk rather than testing everything?

Lived: stories were benefit-ranked in Jira and the QA lead's entry criteria differed by story type; heavy late stories got a drop date. Design: the matrix is at the grain the failure happens — node × channel × transition — and the cells that failed most get automated first.

3. What happens when a release still breaks production?

Roll back the transport group, not the whole release; open a corrective action with a root-cause class; add the missing regression cell so the same class cannot pass again. In the design, the MRP diff cell exists because a release broke MRP. The cell, not the apology, is the corrective action.

4. How did you get engineering to accept a gate written by QA?

Review, not veto: engineering shaped the entry criteria, and I covered some of the low-impact stories they had to drop. Objection became co-ownership. Two cycles on four weeks, and the QA lead was defending the gate herself.

2. J7 · E9 — Migrating a legacy rules engine without unintended deployments: tolerance first, mocks by cause, one publisher DESIGN CASE

DESIGN CASE + LIVED RECORD. E9 (the ERP cutover from a legacy WMS) is a design I wrote in an interview-prep engagement; volumes illustrative. The record under it is lived: **S18** — Sephora RP → JDA WMS migration across two DCs in eight months: a 0.5% reconciliation tolerance published with Finance before mock 1; three mocks at 7% → 1.8% → 0.3%; a 72-hour in-transit freeze; legacy read-only as failback; a $20M ROI pipeline of four programs unblocked (record: resume; master S18). The “one publisher” rule is lived on Sephora UDC: no SKU with two published availability values (user anchor: GFiber v8 S2). **Angle for James:** the governance mechanics — parity, mapping as data, validation before volume, one source of truth per node. Rocky hears S18 as a program and cutover story; do not retell the budget or the team here.

His bullet it answers: “leads migration of a legacy placement rules engine to a next-generation centralized policy platform … architecture decisions, stakeholder alignment, sequencing, training delivery” and “fewer unintended deployments.”
LPs: Insist on the Highest Standards · Dive Deep · Learn and Be Curious · Bias for Action | **Headline:** 7% → 1.8% → 0.3% against a 0.5% tolerance published before the first mock (record).

60-SECOND PITCH

“The closest thing I have run to your rules-engine migration is a WMS migration at Sephora: two DCs on a legacy system with no documentation and an eight-month deadline, and I had never run a WMS migration. The risk was the same as yours — the new platform behaves differently from the old one in a way nobody notices until it ships. So I made ‘good enough’ arithmetic before anyone tested: a 0.5% reconciliation tolerance published with Finance before the first mock. I treated mappings — units of measure, location names, status vocabularies — as data in governed tables, not code. Each mock was read by cause class, never by the headline: 7% was mapping, 1.8% was in-transit timing, 0.3% passed. At cutover a 72-hour freeze, the legacy system read-only as failback, and one rule that I designed from it: zero the old publisher before the new one publishes, so consumers read one source at a time. When hundreds of RF devices failed the conversion script, the rehearsed paper-pick fallback fired instead of a rollback; training moved 1.5 weeks and the date held.”

S — Situation. *Lived (S18, record).* Two Sephora DCs ran a legacy WMS with zero inherited documentation; a hard eight-month deadline gated a $20M ROI pipeline of four programs; inventory accuracy across two DCs could not wobble at cutover. I had never run a WMS migration. *Design case (E9, design).* A site runs a legacy system with its own book; the business wants the new platform to become the book of record with no double-promising during the switch and a Finance-grade reconciliation at go-live.

T — Task. Own the lifecycle — charter, design sign-off, interface inventory, UAT, cutover, hypercare — accountable to the sponsor and Finance, with one test of success that nobody could negotiate after the fact. Translated to a rules-engine migration: prove the new platform produces the same decisions as the old one, within a published tolerance, before it decides anything live.

A — Action. Five gates; each step is lived unless marked design.

- **Discovery — inventory before opinions.** Charter written in week one with the success criteria (on the date, inside a published tolerance, zero accuracy incidents, hypercare exit under two blockers a day). Interface inventory v0 built from message logs; every interface got a named owner and a test cell. I learned the floor in month one until I could walk receive → put-away → pick → ship unaided.
- **Design — tolerance and mapping as data.** The 0.5% tolerance published with Finance before mock 1. Conversion order fixed: masters → open orders → on-hand → in-transit as its own batch. A mapping-table standard: units of measure, locations and status vocabularies as governed data, not code. Stories slotted by business criticality × effort.

- **Build & Test — mocks read by cause.** Three mocks on production data with written root causes. Mock 1 at 7%: units of measure, location names that mapped to nothing, order-status vocabulary. Fixed in the mapping set → 1.8%. In-transit timing → the 72-hour freeze and a separate batch → 0.3%. A total that shrank without a named cause was not evidence.
- **Cutover — one door, one publisher, rehearsed fallbacks.** Written go recommendation off mock 3; the 72-hour in-transit freeze; the legacy system read-only as failback; rollback triggers per interface written in advance (mismatch above 0.5% for two days, or ship-confirm posting failing beyond two hours) — rehearsed, never used. Hundreds of RF devices failed the conversion script; I invoked the rehearsed paper-pick fallback rather than roll back and told leadership training would slip 1.5 weeks. *Design (E9):* zero the legacy availability first, then publish the new — never the reverse.
- **Hypercare — numeric exit.** Blockers per day read daily; exit at under two a day sustained, in week 3 of 4; the exit memo carried the single-point-dependency lesson.

R — Result.

- Reconciliation variance 7% → 1.8% → 0.3% against the 0.5% tolerance published before mock 1 record.
- Two DCs live on JDA in eight months, on time; the $20M ROI pipeline of four programs unblocked the next month — slip avoided, not banked record.
- Per-interface rollback rehearsed and never needed; the paper-pick fallback fired for the RF miss; training moved 1.5 weeks and the go-live date held record.
- Hypercare exited in week 3 at under two blockers a day record. E9 target metric: cutover variance inside the published tolerance with zero double-promises design.

TRADE-OFF I MADE. Options: one mock and a long hypercare, or three full mocks. I chose three — they cost weeks that would otherwise have been spent live. I also chose the 72-hour freeze, which delayed receipts, priced with operations and scheduled off-peak. At the RF failure I chose fallback over rollback: a rollback would have reopened every converted interface to save one floor task.

FAILURE / LEARNING. The RF miss was mine: RF conversion sat on the log as a task, not a risk, because I scored it by effort when impact mattered. Device testing now precedes training, and every single-point dependency gets a what-if plan regardless of size record.

Insist on the Highest Standards — the tolerance was published before I knew I could hit it.
Dive Deep — every mock delta carried a root-cause class and an owner.
Learn and Be Curious — I had never run a WMS migration; I learned the floor in month one.
Bias for Action — the rehearsed fallback fired in minutes instead of a rollback debate.

SAFE-SAY. “Hundreds of RF devices failed the conversion script; we ran the rehearsed paper fallback, training moved a week and a half, and the go-live date held.” Never state a device count. **If asked for source:** “My resume line on the dual-DC migration — three mocks to a published 0.5% tolerance — and the master record S18; the rules-engine framing is design case E9.”

20-SECOND VERSION

“I migrated two DCs off a legacy WMS in eight months by publishing a 0.5% reconciliation tolerance with Finance before the first mock, treating mappings as governed data, and reading every mock by cause: 7%, 1.8%, then 0.3%. At cutover one source published at a time and the fallbacks were rehearsed — one fired, and the date held.”

PROBES JAMES IS LIKELY TO ASK

1. How would that translate to a placement rules engine with no inventory to reconcile?

The “variance” becomes decision parity: replay a frozen set of real placement requests through both engines and diff the decisions by cause class — rule missing, rule translated differently, data mapping, intended change. The tolerance is published before the first replay; intended changes are listed in advance so they are not counted as defects. design

2. How do you avoid two engines deciding at once?

One publisher per node at a time: the legacy engine stops deciding for a node before the platform starts, never the reverse, with the switch logged. On UDC the rule was no SKU with two published availability values; here it would be no node with two active rule sources.

3. What were your rollback triggers?

Written in the charter before go-live: mismatch above tolerance for two days, or posting failing beyond two hours, with rollback per interface and the legacy system read-only as the failback. Rehearsed; never used. Per-interface rollback is why one bad interface never forced a full rollback.

4. What would you do differently?

Score dependencies by impact, not effort. The RF conversion looked small, so it was a task rather than a risk. Now any dependency that can stop the floor gets a rehearsed fallback and a test before training.

3. AI-assisted configuration tooling — operator self-service with guardrails ONE PAGE

Lived analog and angle. I1 / Apple A01 — an LLM incident-triage agent I built independently (Python/FastAPI), **not an employer production deployment** (record: Apple v11 I1, pp. 41–42). Venkata may hear I1 as a product story; James hears only the **guardrails, validation and operator self-service** angle.

THE ANSWER (ABOUT 60 SECONDS)

"I built an independent LLM triage agent as an operations product, not a demo. Three guardrails made it safe. First, the eval set came before any prompt or model change: I graded historical incidents with known-correct outcomes, and every change had to keep the past passing — a pre-deployment validation gate. Second, 'no citation, no proposal': every recommendation had to cite the ticket evidence and the runbook line. Third, tiered routing: easy, well-understood classes went to small models; the expensive path was reserved for the hard tail. Cost went from $25 to $0.40 per incident, a 98% cut, with accuracy held on the eval set and 100% citation coverage. For configuration tooling I would keep those three and add one: the tool proposes, a validator decides, and the operator approves a readable diff before anything deploys."

S — The naive agent cost $25 per incident and could answer without checkable evidence, so the human repeated the work. **T —** Quality held on known cases, every proposal checkable, unit cost below a dollar. record

A — Eval set graded first and made the release gate; "no citation, no proposal"; cost measured per class and routine classes routed to smaller models; accuracy, citation coverage and unit cost reviewed together. record

R — $25 → $0.40 per triaged incident (98% reduction); accuracy held on the eval set; 100% citation coverage. record

GUARDRAIL I BUILT (I1, RECORD)	CONFIGURATION-TOOLING EQUIVALENT (DESIGN)	LIVED EVIDENCE THAT THE PATTERN WORKS AT NETWORK SCALE
Eval set of graded historical cases; every change must keep the past passing	A regression pack of past network changes and known-good outcomes; a proposed change is replayed against it before deploy	S18 mocks read by cause against a published tolerance; E8 MRP diff cell record / design
No citation, no proposal	Every generated change cites the rule, SOP step and data row it relies on; uncited changes cannot be submitted	UDC 44-row register: one change, one system, one owner per row record-from-docs
Tiered routing — easy classes to small models, hard tail reserved	Low-blast-radius change classes self-serve; new node types, escape routes and capacity signals route to a specialist review	Canada node enablement: six changes, five small, run by a seven-step script before the nightly batch record-from-docs
Accuracy, citations and cost read together	Weekly metrics: changes self-served, validation-fail rate, rollbacks, unintended deployments, review latency	S15 drop-date reason codes made late work visible record
Human approval kept until evidence beats the human baseline	Operator approves a readable before/after diff; auto-approve only for classes with a clean record	A5 launch gate: shadow accounts on named customers, 80% minor-to-no-issues bar before customer-facing use record

TRADE-OFF I MADE. One expensive model for every case was simpler; tiered routing added routing logic and eval upkeep but kept quality and made the economics viable. For operators: more change classes to govern, in exchange for self-service that is safe by default.

FAILURE / LEARNING. My early eval set was still growing while prompts were being judged, so early comparisons were not like-for-like. I would freeze and version the baseline before the first experiment — for configuration tooling, version the regression pack with every rule release. record

LPs: Invent and Simplify (self-service with guardrails built in) · Insist on the Highest Standards (no citation, no proposal) · Frugality ($25 → $0.40) · Dive Deep (graded history before changes).

SAFE-SAY. "This was my independent build, not an employer production program: $25 to $0.40 per triaged incident, quality held on my graded eval set, and every proposal cited." **Source:** "My build records, captured in Apple workbook I1, pages 41–42." **20 seconds:** "I built an incident-triage agent with the eval set first and one rule — no citation, no proposal. Cost fell from $25 to $0.40 per incident with quality held. For configuration tooling: the tool proposes, a validator decides, the operator approves the diff."

Probe: what breaks at Amazon scale?

Access review, data boundaries, regression-pack upkeep and drift become programs of their own; keep human approval until production evidence beats the human baseline. design

4. Legacy rules engine → policy platform: how I would sequence it DESIGN ANSWER

DESIGN ANSWER ON LIVED EVIDENCE. I have not migrated a placement rules engine. Each step below is my proposed sequence (**design**), and each is backed by a mechanism I ran (**record / record-from-docs**). UDC rows: same Sephora UDC umbrella Rocky may have heard; governance facet only.

THE ANSWER (ABOUT 45 SECONDS)

"I would sequence it in seven steps, and none of them deploys anything until parity is proven. Inventory every legacy rule as a row with an owner and a test cell. Publish the parity tolerance before the first replay, so 'good enough' is arithmetic. Run the platform in shadow, deciding alongside the legacy engine but executing nothing, and read every disagreement by cause. Cut over in waves by node type, with one rule source per node at a time. Then every change rides pre-deployment validation, rollback triggers are written in advance, and legacy retires only when every consumer has a destination."

STEP	WHAT I WOULD DO (DESIGN)	EXIT GATE	LIVED EVIDENCE
1. Parity matrix	Every legacy rule as a row: rule, node types touched, owner, test cell, and an "intended change" flag so planned differences are not counted as defects	Every rule owned; intended deltas signed	UDC: 44 numbered rows across 23 systems, one change and one system per row (council deck pp. 13–14) record-from-docs ; S18 interface inventory from message logs, owner + test cell each record
2. Tolerance, then replay	Publish the decision-parity tolerance with Operations and Finance; replay a frozen set of real placement requests through both engines; diff by cause class	Replay inside tolerance, every delta classed	S18: 0.5% published before mock 1; 7% → 1.8% → 0.3%, each mock removing a named cause record
3. Shadow mode	Platform decides alongside legacy, logged not executed, on live volume; disagreements triaged daily	Disagreement rate flat at or below tolerance for an agreed run	Flexport launch gate: shadow accounts on named customers, 80% minor-to-no-issues bar before customer-facing use (A5) record ; UDC interim bridge: planning auto-copied 801 → 900 so it saw one node before the floor did (rows 19, 21) record-from-docs
4. Waves by node type	Simplest node type first, then crossdock, then new node types; one rule source per node at a time — legacy stops deciding before the platform starts, switch logged	Wave exit on numbers, not dates	Canada: 99 brands in waves of 20 / 40 / 39 (discovery p. 16) record-from-docs ; UDC: no SKU with two published availability values user anchor
5. Pre-deployment validation	After cutover every change rides a manifest: replay against the regression pack, readable diff, approval by change class, audit row	Unintended deployments trending to zero	Canada: five business data sets, seven IT steps before the nightly planning batch (p. 19) record-from-docs ; E8 train design ; S15 QA-owned gate record
6. Rollback	Per node and per rule set, triggers written before go-live; legacy kept read-only through the failback window	Rehearsed in the last mock	S18: rollback per interface, triggers written in advance, legacy read-only as failback; rehearsed, never used record
7. SOPs, training, decommission	Runbook per change class; train on real changes once tooling is proven; retire legacy only when every consumer has a destination	Zero orphan consumers	A4: all 79 legacy Crux customers ($185,892 ARR) given migrate / white-label / cancel paths before retirement record-from-docs ; S18 RF lesson — device test before training record ; S15 user guide copied by neighbouring teams record

Weekly metrics (design): parity vs tolerance by node type · unintended deployments per hundred changes · validation-fail rate · rollbacks by cause · share self-served · legacy consumers without a destination.
TRADE-OFF I WOULD MAKE. Waves by node type over a big-bang switch: running two engines in parallel costs maintenance and dual-run time, but it bounds the blast radius of any rule I translated wrongly to one node type. **FAILURE / LEARNING (A4, record):** at Flexport I set the canonical-source rule after the first executive comparison; once dashboards have constituencies, a cheap definition becomes an expensive negotiation. Here I would publish the parity metric before anyone sees a shadow-mode number.

SAFE-SAY. "I haven't migrated a placement rules engine; this is how I would sequence it, and every step is a mechanism I have run — the 44-row register at Sephora, the three-mock migration and the Flexport decommission." **Source:** "The UDC architecture-council deck, the Canada discovery deck, my resume line on the dual-DC migration and the Crux transition RAPID." **LPs:** Think Big · Insist on the Highest Standards · Dive Deep · Ownership.

PART 5 — VENKATA JOSYULA — PRODUCT + BEHAVIORAL (BAR-RAISER STYLE) · 12:00 PM PDT FRI OCT 30, 2026 · THE LAST INTERVIEW OF THE LOOP

Amazon — Senior Supply Chain Manager, NACF Supply Chain (L6) · Rajesh Rishiyur Chandrasekaran · Interviewer: Principal PM, FBA

Shipment Visibility as a product story · the Crux transition as a product story · product-sense add-ons · 16-LP self-audit

Everything in STAR, first person. Companion files by other workers: **-josyula-extra-stories-star** (S14, S16, S9, S13, I1, G1 full STAR) and **-josyula-star-bank-star** (32-answer LP bank). This file does not repeat them. V3 points to the UDC pack B4 and does not rewrite it.

Contents

0. CRAM SHEET — bar-raiser edition (what he tests · order of stories · 5 numbers · 3 opening sentences · 16-LP self-audit)

V1 · Shipment Visibility — the PRODUCT story (customer problem → discovery → MVP cuts → graduation gates → adoption 7 → 68 → cost to serve $0.66 → $0.03) · full STAR + compact failure STAR

V2 · Crux customer transition — the PRODUCT story (what to retire vs keep · segmentation · parity as the contract · shadow accounts · comms · metrics) · full STAR

V3 · "One promise per customer, in both countries" — pointer to UDC pack B4 (not rewritten)

P1–P4 · Product-sense add-ons (short STAR): what I did NOT build · adoption vs usage vs outcome · a sunset · customer ask vs roadmap

VERIFY list and source trace (short)

0. CRAM SHEET — bar-raiser edition

> **Who he is:** Venkata Josyula, Principal PM, FBA (Fulfillment by Amazon). A product person running the behavioral/LP slot. Earlier plan listed him as bar raiser; today's schedule put the Bar Raiser badge on Rocky — **prepare as if Venkata is the bar raiser anyway**: he can veto, he will probe depth, and he will cross-check what the hiring manager and Ryan heard yesterday.
>
> **What a bar raiser tests:** (1) **LP depth** — one story, five layers down; (2) **"I" vs "we"** — what I personally decided, built, wrote, said; (3) **data-driven honesty** — numbers with a basis, a target called a target, a miss called a miss; (4) **long-term thinking** — mechanisms that outlived me; (5) **raising the bar** — would he be happy to have me on his team at L6.
>
> **Already told yesterday (never primary again, except SV by explicit exception as a product story):** S/4 HANA / ISM · Flexport estimation / FF App · Shipment Visibility (operating lens) · safety stock · 200-lane lead time. If he asks about SV, say up front: "Snigdha heard the operating side; the product side is a different story."

ORDER OF STORIES (12:00 SLOT, ~45 MINUTES OF QUESTIONS)

#	IF HE ASKS…	STORY (FILE)	NUMBER IT LANDS (BASIS)
1	"Tell me about a product you built / took from zero to scale"	**V1 Shipment Visibility — product lens** (this file)	7 → 68 customers, 9.7× (record); cost to serve $0.66 → $0.03, about 95% (record)
2	"Tell me about a time you had to sunset / migrate customers / say no"	**V2 Crux transition — product lens** (this file)	79 customers, $185,892 ARR, 294,581 containers in 2021 (record-from-docs, RAPID e582); 55 to transition, 24 to redirect or cancel
3	Customer Obsession / Earn Trust	S14 trust (extra-stories file)	about 200 orders, $2.5M of order value (user anchor); $10M initiative won — not savings

#	IF HE ASKS…	STORY (FILE)	NUMBER IT LANDS (BASIS)
4	Ownership / Invent and Simplify	S16 pipeline (extra-stories file)	four systems → one; accuracy 60% → 90% (record); value priced, not saved
5	Think Big / Backbone	S9 thousand-lane program (extra-stories file)	597 lanes carrying 80% of spend first (user anchor)
6	Bias for Action / Deliver Results	S13 crisis (extra-stories file)	99% fill; about $8M of that day's sales protected (record)
7	"Tell me about a failure"	G1 UAT concurrency miss (extra-stories file); short failure inside V1 (monitoring came late)	five users × ten scenarios passed; all-user concurrency failed two days before sign-off (record)
8	Learn and Be Curious / Frugality (AI)	I1 LLM triage (extra-stories file)	$25 → $0.40 per incident, 98% cut; 100% citations (record)
9	Product-sense probes	P1–P4 (this file) · UDC pack B4 pointer	see each

The 5 numbers never to get wrong.
1. **7 → 68 customers = 9.7×** (record). Never a bigger multiplier; never "ten times."
2. **$0.66 → $0.03 per container, about 95%** (record). The $1.00 hand-carried start only if asked.
3. **170 monthly active users — a public target, landed; 32,000 shipments — a target**, never "achieved" (record).
4. **Crux base: 79 customers · $185,892 ARR · 294,581 containers (2021)** (record-from-docs). Two truck brokers were most of the volume.
5. **Nine teams, close to 100 people; automation 40% → 90%; ticket response 72% → 90%** (record). The $3.22M cost-to-serve figure is the 2021 plan's *target*, not my result.

3 opening sentences (pick by question).
• "Snigdha heard how I ran Shipment Visibility; let me tell you the product decisions underneath it — what we refused to build so that seven customers could become sixty-eight."
• "The hardest product call I was part of was retiring a product seventy-nine customers were paying for — and deciding, segment by segment, who we would carry over and who we would not."
• "I measure a product on three different numbers and I will tell you which one I got wrong first: adoption, usage, and the outcome the customer actually paid for."
If/when he asks 'what did YOU own?': "I was the technical program manager; the product DRI was Frank te Pas. I owned the pilot machine — graduation gates, testing approach, go/no-go, monitoring, the 3PL ingestion decision — and I co-owned scope cuts with him. I will say 'I' where it was mine and 'we' where it wasn't."

16-LP SELF-AUDIT — STRONGEST EVIDENCE LINE + NUMBER + THE SOFT SPOT I NAME FIRST

LP	STRONGEST EVIDENCE LINE (STORY)	NUMBER (BASIS)	SOFT SPOT TO NAME FIRST
Customer Obsession	Pilot customers used SV free for the whole pilot; light onboarding so their investment stayed small until we earned it (V1). S14: the customer heard it from me first.	CSAT gate = parity with average consignee CSAT (record-from-docs)	The analyst / internal customer was under-served in UDC (B4) — I say that before he finds it.
Ownership	Monitoring came late and bugs took hours to localise; I owned the miss in the year-end review and made E2E monitoring a launch gate (V1 failure). S16: wrote myself out of the Monday number.	Hours per bug → "customer-ready 11/19" monitoring list (record-from-docs)	Program delays in 2021 were real; I do not blame the infrastructure.
Invent and Simplify	Graduation by six published criteria instead of a date; shadow accounts fed with the customer's own Crux data (V1, V2). S16 four systems → one.	6 criteria; 50-container calibration bar (record-from-docs)	Simplification came after complexity: 6+ system layers was our own design.
Are Right, A Lot	Held Wave 3 once on ETA accuracy; zero rollbacks (V1). Crux: segment decisions, not a blanket cancel (V2).	Wave 3 held once; 0 rollbacks (record)	Testing effort estimate was overly optimistic — my judgement error (record).

LP	STRONGEST EVIDENCE LINE (STORY)	NUMBER (BASIS)	SOFT SPOT TO NAME FIRST
Learn and Be Curious	Learned the event flow through six systems well enough to find the missing trace id (V1). I1: built an LLM eval contract.	2–4 hours per bug before trace ids (record-from-docs)	I learned it during testing, not during design.
Hire and Develop the Best	Expanded testing from engineers to business users (UAT) once data quality hit 80%; the testers became the pilot's feedback owners (V1).	UAT started at 80% shipments minor-or-no issues (record-from-docs)	Thin: I led through influence, not as a people manager — say it.
Insist on the Highest Standards	A 99.4% week on three touches was discarded rather than reported (V1). Verification SLA ≥ 90%.	99.4% week discarded (record)	The standard existed because an earlier week had been reported too kindly.
Think Big	SV was positioned as the 4PL control tower and the flywheel to Visibility-as-a-Service (V1). S9: a thousand-lane ask became a standard.	2021 plan: 18 → 64 automated milestones target (record-from-docs)	VaaS was unfunded; I describe the flywheel as the plan, not a result.
Bias for Action	Chose a production test account for 3PL ingestion rather than wait for 4PL volume to grow (V1 / P1). S13: acted at 4 AM.	300 containers, Trans-Pacific first (record-from-docs)	Acting earlier on monitoring would have saved more than acting fast on testing.
Frugality	Free pilot; CSV upload before API; “no extra dev effort” path for forwarders in the Crux decision (V1, V2). I1: $25 → $0.40.	FF/CB/3PL → SV API, no extra dev (record-from-docs)	Frugality on monitoring cost us hours per bug — false economy, owned.
Earn Trust	Told the E-Team that data quality, not the public website, was the priority — and wrote the misses into the year-end review (V1).	Year-end: 3 wins, 3 misses written (record-from-docs)	Pilot clients heard “pilot” dates slip in 2021; we told them.
Dive Deep	Event-grain automation measured, not estimated: load-event tracing, events in vs out per system (V1).	Events originating / destination per system (record-from-docs)	Scraper error rates were ~5% air / ~9% ocean against a 10% bar — close to the line.
Have Backbone; Disagree and Commit	Crux: argued not to eject customers without a parity view; committed to the segment decisions once made (V2). S9: 597 first, two levels up.	55 transition / 24 redirect-or-cancel (record-from-docs)	I was Input, not Decide, on that RAPID — I say so.
Deliver Results	Both public targets — 68 customers and 170 users — landed two months early (V1).	68 / 170, two months early (record)	32,000 shipments was a target we managed toward; I cannot tie it to the workbook.
Strive to be Earth's Best Employer	Daily stand-ups and scrum-of-scrums kept nine teams from burning out on blame; the retrospective named systems, not people (V1).	9 teams, ~100 people (record)	“Long hours” is in the record — the environment build cost people evenings.
Success and Scale Bring Broad Responsibility	Crux customers were told, by segment, what would happen to them before wind-down; competitors cut with legal review, not quietly (V2).	Cancellations dated Aug 1 / Sep 1 / Oct 24, 2022 (record-from-docs)	“Ejecting customers is never a good experience” — a stakeholder's line I adopted.

V1 · Shipment Visibility — the PRODUCT story: customer problem → discovery → MVP cuts → graduation gates → adoption → cost to serve

DIFFERENT ANGLE FROM THE HIRING MANAGER

Angle rule: Snigdha heard the operating/estimation lens (waves, WBR, pre-production measurement). Venkata hears the product lens: who the customer was, what we learned in discovery, what the MVP left out, what the graduation gates were and why, what we said no to, build-vs-buy, how success was measured and how adoption became outcome. Same facts, different story.

My role, honestly: Technical Program Manager for the Shipment Visibility initiative (Path to 4PL names Thanai Kumar and me as TPMs; DRI Frank te Pas). Product decisions were co-owned with Frank; the pilot machine, gates, testing, monitoring and the 3PL ingestion decision were mine.

LPs: Customer Obsession · Invent and Simplify · Insist on the Highest Standards · Deliver Results. **Headline numbers:** 7 → 68 customers, 9.7× (record); cost to serve $0.66 → $0.03 per container, about 95% (record); nine teams, ~100 people (record).

60-SECOND PITCH

The customer was an importer who could see their Flexport freight perfectly and everything else — the containers moving with other forwarders — not at all. Flexport's own track-and-trace was human-powered: people in Data Services keying milestones, at about sixty-six cents a container. The product bet was to replace that with an automated visibility service and open it to the customer's whole supply chain — the 4PL “single pane of glass.” I was the TPM across nine teams and close to a hundred people; the product DRI and I co-owned the scope. The product decisions that mattered: we launched to two pilot customers, free, with CSV upload before API; we published six graduation criteria — verification SLA ninety percent of the time, data at least as accurate as the legacy Crux product, milestone accuracy eighty percent, stable production, real engagement of at least a hundred containers, and no show-stoppers — and a wave graduated only when it met them. We held Wave 3 once on ETA accuracy and never rolled anything back. We said no to a public tracking website until data quality and cost to serve were fixed. Result: seven pilot customers to sixty-eight — nine-point-seven times — both public targets two months early, and cost to serve from sixty-six cents to three cents a container, about ninety-five percent. The miss I own: monitoring came late, and for weeks a bug took hours to localise.

S — Situation. Flexport's visibility team was created in May 2020 with a mandate to own all track-and-trace milestones; by the start of 2021 only 18 of 99 milestones were actively worked and none were fully automated (2021 Product Development Plan, record-from-docs). Track-and-trace was a cost line — Data Services people keying updates — and the customer could only see Flexport-moved freight. The 2021 plan set two funded initiatives (automate Flexport milestones; build non-Flexport “Shipment Visibility” in the Client App) and one unfunded (Visibility-as-a-Service), with a legacy acquired product, Crux, still serving 79 paying customers.

T — Task. Launch Shipment Visibility as a 4PL product on new infrastructure, fully integrated into the Flexport platform, to pilot customers by late 2021, and scale it in 2022 while the cost to serve fell — without letting a half-accurate product reach customers. I owned the program and the pilot machine; I co-owned scope with the product DRI.

A — Action (the product decisions, in order).

- **1 · Customer problem and persona, written first.** Target: importers and exporters, Enterprise and global key accounts first, with a plan to scale to SMB later (E-Team takeaways, Feb 1 2022). Non-target, not anti-persona: drayage operators and forwarding partners. The job story set — “4PL Shipment Visibility Job Stories — MVP” — was the single reference every tester used when unsure of intended behaviour (Product Testing Approach).

- **2 · Discovery and the MVP cut.** MVP = tracking request by single input, CSV and API; dashboard, shipment list, shipment details, reporting, messaging. Cut from v1: public tracking website (deferred until data quality and cost to serve were fixed — an E-Team decision I supported), source-toggling and usage-audit for future charging (deferred until additional sources arrived, Q2–Q3 2022), paid tiers (free for the whole pilot). Light-weight onboarding by design: API integrations and letters of authority only after Wave 2, once we were confident the product was meeting expectations.
- **3 · Build vs buy.** We did not buy Project44 data: “invest in making our solution better even if it is with Data Services to start” (E-Team, record-from-docs). The reason was product, not pride — visibility was the competitive advantage and the data flywheel, and P44 served a different segment. We did keep buying raw sources (CargoSmart first) and human-in-the-loop for the automation gaps.
- **4 · Graduation gates instead of dates.** I wrote the pilot into waves — Wave 1 two customers (~Q4 2021), Wave 2 four, Wave 3 twenty-plus, full roll-out H2 2022 — and six published graduation criteria: verification SLA met 90% of the time (automated review within 24h, manual within 24h, nothing “in progress” beyond 48h); internal data quality ≥ 90% and at least as accurate as Crux; milestone/ETA accuracy ≥ 80%; production stable at Flexport standards; meaningful engagement (≥ 100 containers uploaded, key features tried); customer feedback with no show-stoppers and CSAT at parity with average consignee CSAT. Entry bar: a new customer gives us at least 50 containers so the product is calibrated before they log in (Pilot Roll-out Schedule, record-from-docs).
- **5 · Testing as product discovery.** Four tests I ran before launch: the “100 container test” (random containers and bills of lading, bugs to Jira, daily stand-up), bi-weekly bug bashes against job-story ranges, **shadow customer accounts** fed with the customer's own Crux uploads so we compared side by side, and UAT with business users once 80% of shipments had minor or no issues. Go/no-go had two meetings — business and tech — on three criteria: stable production, one pilot customer's data quality ≥ 80%, no show-stoppers.
- **6 · Volume as a product input.** With 4PL volume growing slowly, I took the decision to create a production test account and ingest 3PL volume — 300 containers, Trans-Pacific lanes first, Crux-only customers as the source — to find inaccuracies faster, with explicit non-goals (not a performance test, not a cost-to-serve comparison) and a switch list so no live customer could be disturbed (3PL ingestion one-pager, record-from-docs).
- **7 · Prioritisation of data quality.** Carriers, terminals and milestones were prioritised on the Trans-Pacific eastbound and trans-Atlantic westbound lanes, ordered by cost-to-serve reduction and then by ease of getting the data; a weekly visibility review with POD-ETA accuracy and interaction elimination as the first two numbers (E-Team actions).
- **8 · How success was measured.** Three ladders kept separate: adoption (customers), usage (monthly active users, containers uploaded, features touched) and outcome (cost to serve per container, automation rate, ticket response). The weekly review format was borrowed from the LSA review: input → output, red/green at ±5%.

R — Result.

- **Customer / adoption** — 7 pilot customers → 68, 9.7× (record); 45 waitlist sign-ups at FORWARD (record-from-docs); both public targets — 68 customers and 170 monthly active users — landed two months early (record). 32,000 shipments was the target we managed toward (record).
- **$ / outcome** — cost to serve $0.66 → $0.03 per container, about 95% (record); the 2021 plan's $3.22M automation target was the plan's number, not my claim.
- **%** — automation 40% → 90% through a 70% no-touch gate (record); ticket response 72% → 90% at five times the volume (record); scraper error rates about 5% air / 9% ocean against a 10% bar (record-from-docs).
- **Quality** — Wave 3 held once on ETA accuracy; zero rollbacks; a 99.4% week built on three manual touches was discarded, not reported (record).
- **Time** — launched December 2021 on new infrastructure, fully integrated, announced at FORWARD, in pilot customers' hands (record-from-docs). The pilot itself slipped several times in 2021 (record-from-docs — owned below).

TRADE-OFF I MADE. Options: (a) launch broad with the legacy Crux feature set re-built; (b) launch narrow and free to two customers behind published gates; (c) launch a public website for volume first. I chose (b) and argued for deferring

(c): fewer features, a free pilot, CSV before API, and graduation by criteria rather than calendar. Rejected (a) because feature parity before data quality would have shipped a confident-looking product with wrong milestones. Cost: slower top-line adoption in H1 2022, a waitlist that waited, and pilot customers who could not yet integrate by API. **Failure / learning line:** I under-estimated product testing effort and let monitoring come after debugging — a bug could take hours to localise across six-plus system layers; now end-to-end monitoring is a launch gate, not a follow-up.

LP proof lines. Customer Obsession — free pilot, light onboarding so the customer's investment stayed small until the product earned it; CSAT parity as a graduation gate. **Invent and Simplify** — six criteria replaced a date; shadow accounts turned the customer's own data into the test bed. **Insist on the Highest Standards** — Wave 3 held; the 99.4% week discarded. **Deliver Results** — 68 and 170 two months early; cost to serve down about 95%.

SAFE-SAY. Most attackable number: “Nine-point-seven times is seven pilot customers to sixty-eight monthly active customers — the workbook's count, not a revenue multiple; cost to serve is sixty-six cents to three cents per container, about ninety-five percent, and I will not round it further.” Source question: “The pilot roll-out schedule, the product testing approach, the year-end Path-to-4PL review, the E-Team takeaways of February 2022 and the weekly visibility review — I can walk you through any of them.”

20-SECOND VERSION

Importers could see their Flexport freight and nothing else; our own tracking was people keying milestones at sixty-six cents a container. We launched Shipment Visibility free to two customers behind six published graduation criteria, said no to a public website until data quality was fixed, and let the customer's own data test the product. Seven customers became sixty-eight, nine-point-seven times; cost to serve fell to three cents, about ninety-five percent.

Compact failure STAR inside V1 — monitoring came late (owned in the year-end review)

S. Data travelled through six-plus system layers, many brand new, with limited monitoring in each. **T.** Reach the data-quality bar for pilot launch while bugs from the bug bashes were being triaged daily. **A.** I noticed while reading application logs that no unique id tied an event from the downstream source to the customer-facing screen, so every blocker took two to four hours just to locate. I proposed a design change — trace the load event end to end, count events in versus events out at every system boundary — and built the “customer-ready by 11/19” monitoring list across Client App, Forwarding, Ocean, Visibility, Data Access and the public API, with Datadog monitors and a consolidated view prioritised for production. **R.** Faster localisation of blocker bugs (my note at the time claimed about half the time to resolve — treat as my estimate, not a measured record); monitoring became part of the launch definition and of the later 3PL test. In the year-end review I wrote the miss plainly: “we should have increased focus on implementing robust system monitoring earlier in the lifecycle.” **What I do differently:** observability is a line in the MVP, with an owner and a date, before the first bug bash.

PROBING Q&A

You were the TPM. What product decision was actually yours?

Three I will defend as mine: graduation by six published criteria instead of a date, including the 50-container calibration entry bar; the production 3PL test account to get volume for accuracy work with explicit non-goals and kill switches; and the trace-id design change that made monitoring possible. Scope cuts — public website deferred, free pilot, CSV before API — were co-owned with the product DRI and ratified by the E-Team; I argued for them, I did not decide them alone.

Why not just buy Project44 data and ship faster?

Because visibility data was the moat and the flywheel: every tracking request taught us where coverage was weak. The E-Team chose to invest in our own solution, with Data Services covering gaps, and to compare ourselves to P44 explicitly rather than depend on it. Different target segment too — they served global key accounts; we needed Enterprise and later SMB. I would make the same call; I would start the competitive analysis a quarter earlier.

How did you know the product was working and not just adopted?

Three ladders, never collapsed into one: adoption — customers on the platform; usage — monthly active users, containers uploaded, features touched, with a hundred-container engagement gate; outcome — cost to serve per container and automation rate. A customer who uploaded ten containers and left counted against us even though they were “adopted.”

What did you get wrong?

Testing effort — I estimated it as if the product were one system and it was six. And monitoring came after debugging instead of before. Both are in the year-end review in my words. The fix I carry: observability and test effort are sized per system boundary, not per product.

V2 · The Crux customer transition — the PRODUCT story: what to retire vs keep, segmentation, parity as the contract, shadow accounts, comms, success metrics

PRODUCT LENS — NOT THE CUTOVER RUNBOOK, NOT THE RELIABILITY ANALYTICS

Angle rule: Rocky may hear the cutover-runbook lens; James hears the apples-to-apples reliability analytics (A4). Venkata hears the product decision: a legacy acquired product with 79 paying customers, a new product that only some of them fit, and a segment-by-segment answer to “who do we carry over, who do we redirect, who do we cancel — and what is the contract we owe them before we switch anything off.”

My role, honestly: the RAPID (newest version e582) lists Recommend: Jennifer, Carol · Agree: James · Perform: Jennifer, Emily · Decide: Sanne; Input from product, engineering and trucking leaders. I am not named on it. I owned the **migration machinery** the decision depended on: the Crux migration plan inside the pilot roll-out schedule, the shadow accounts fed with Crux data, the “at least as accurate as Crux” gate, and the 3PL/Crux-volume test. Say: “I was input and the owner of the transition mechanics, not the decider.” **VERIFY:** whether I personally authored the written feature-parity list a stakeholder asked for in the RAPID.

LPs: Customer Obsession · Have Backbone, Disagree and Commit · Success and Scale Bring Broad Responsibility · Earn Trust. **Headline numbers (record-from-docs, RAPID e582):** 79 customers · $15,491 MRR · $185,892 ARR · 294,581 containers tracked in 2021; 55 in the segments we transitioned (2 GKA, 14 Enterprise, 39 SMB), 24 redirected or cancelled (9 motor carriers, 3 truck brokers, 5 forwarders, 1 customs broker, 4 3PLs, 2 SCM SaaS).

60-SECOND PITCH

Crux was a container-tracking product Flexport had acquired; by 2022 it had seventy-nine paying customers, about a hundred-and-eighty-six thousand dollars of annual revenue and nearly three hundred thousand containers a year — and we were building Shipment Visibility to replace it. The product question was not “how do we migrate,” it was “who should we migrate.” Importers and exporters — two global accounts, fourteen enterprise, thirty-nine SMB — were our target customer and moved to Shipment Visibility. The rest were not: motor carriers, truck brokers, forwarders, a customs broker, 3PLs, and two supply-chain-software companies who were effectively competitors. Three-quarters of the container volume sat with two truck brokers. I was input to that decision and I owned the mechanics that made it safe to make: the migration plan tied to the pilot waves, shadow accounts where we ran the customer's own Crux uploads through the new product side by side, and a graduation gate that said the new data had to be at least as accurate as Crux before a customer was moved. The decision, segment by segment: transition the importers; offer the brokers a partner path through our trucking product or cancel at wind-down; offer forwarders the API with no extra development; cancel the two software competitors after legal review. The learning I keep: a stakeholder asked, “is the feature gap between Crux and the new product written down?” — and the honest answer was “not well enough.” Parity has to be a document before it is a promise.

S — Situation. The aim was to migrate Crux customers to Shipment Visibility by the end of 2022 (RAPID, Opportunity). Not all 79 were the right fit for a 4PL visibility service built for importers and exporters. The base: 79 customers, $185,892 ARR, 294,581 containers in 2021; the two largest were truck brokers (AV Logistics, ITS Logistics) — the truck-broker segment alone was $139,512 ARR and 221,044 containers, roughly three-quarters of both. Customer acquisition is expensive; ejecting customers is a bad experience; keeping two systems alive has a cost nobody had written down (stakeholder inputs on the RAPID).

T — Task. For the product team: decide, per segment, retire / redirect / carry over, and the comms. For me: make the carry-over safe — a dated migration plan, a parity contract the customer could hold us to, and a test method that used the customer's own data before they ever logged in.

A — Action.

- **1 · Segmentation before scheduling.** Nine customer types with count, MRR, ARR and 2021 containers each (RAPID table). Rule we applied: *is this a customer of the product we are building, or a customer of the product we are retiring?* Importers/exporters (GKA, Enterprise, SMB) = the former; carriers, brokers, forwarders, customs brokers, 3PLs and SCM-SaaS = the latter, each with its own answer rather than a blanket cancel.
- **2 · What to retire vs keep.** Keep: tracking of the customer's own containers, CSV/API input, milestone display and reporting — in the new product. Retire: Crux as an app, and with it tracking of non-Flexport freight for trucking partners — the decision explicitly said Transmission would *not* add non-Flexport container tracking "at this time." Not carried over: customer types whose use of Crux was competitive intelligence on our own customers (the customs broker tracking for a shoe brand; the two SCM-SaaS platforms).
- **3 · Parity as the product contract.** The graduation gate I wrote into the pilot schedule: internal data quality ≥ 90% *and at least as accurate as Crux* on the track-and-trace data shown to customers, with engineering dashboards built to measure it; verification SLA ≥ 90%; milestone accuracy ≥ 80%; CSAT at parity with average consignee CSAT. That was the promise to a Crux customer: you move when the new product is provably not worse on your data. A stakeholder's question — "what are the missing features, and is the roadmap to parity written down?" — showed the *feature* side of parity was weaker than the *data* side; we owed a written matrix (VERIFY my authorship).
- **4 · Shadow accounts.** Before any Crux customer was invited, we took their Crux container uploads and ran them in a dedicated shadow account in the new product ("SV Test – <customer>"), starting with two Crux customers, bugs to Jira daily — then expanded once UAT was reached (Product Testing Approach). For 3PL/Crux-only volume we used a production test account with 300 containers, Trans-Pacific first, with a kill-switch list so no live customer was touched (3PL ingestion one-pager).
- **5 · Sequencing tied to the pilot waves.** Wave 3 (~Q2 2022) was the first wave to mix Crux and non-Crux customers; full roll-out (H2 2022) carried the remaining Crux customers; the Crux migration plan was updated at each wave review (Pilot Roll-out Schedule). Entry bar per customer: 50 containers for calibration before onboarding.
- **6 · Comms and the decision record.** A RAPID with named roles and written stakeholder input, a decision per segment, an "inform" step and explicit commitments by each impacted party. Cancellations were dated and, for the competitor platforms, run through legal review: one SCM-SaaS customer cancelled August 1, 2022, the customs broker September 1, 2022, the second SCM-SaaS October 24, 2022 (RAPID e582 appendix).
- **7 · Success metrics for the transition.** Customers migrated by wave against the end-2022 aim; data-quality parity held per migrated customer; verification SLA and CSAT at gate; and — the honest one — churn named in the appendix rather than hidden (several Crux accounts are marked "churned" in the record).

R — Result.

- **Decision** — segment by segment, written and committed: importers/exporters (55 of 79) transitioned to Shipment Visibility; truck brokers offered a Transmission partner path or cancelled at wind-down; motor carriers cancelled at wind-down; forwarders, customs broker and 3PLs offered the SV API with no extra development or cancelled; both SCM-SaaS customers cancelled (record-from-docs).
- # — 79 customers, $185,892 ARR, 294,581 containers triaged; 24 customers in redirect-or-cancel segments, carrying about three-quarters of the containers — the volume we chose not to chase (record-from-docs).
- **Quality** — no Crux customer moved ahead of the "at least as accurate as Crux" gate; the product that received them had held Wave 3 once on ETA accuracy with zero rollbacks (record).
- **Customer** — the parity gate and the shadow accounts meant a migrating customer saw their own containers tracked correctly before they were asked to switch (record-from-docs).
- **What I cannot claim** — the dollar cost of keeping Crux alive and the final count migrated by December 2022 are not in my sources (VERIFY).

TRADE-OFF I MADE (and advocated for). Options: (a) cancel all non-importer Crux customers now and stop paying to keep the app alive; (b) keep everyone on Crux until the new product reached feature parity; (c) segment — carry over the target customers behind a data-parity gate, redirect those who fit another Flexport product, cancel those we would never serve. I argued for (c) with the gate, against (a) because it ejected customers without a parity view and

against (b) because the end-2022 wind-down and the cost of two systems made it a slow version of (a). Cost: we walked away from about three-quarters of the tracked volume and the largest ARR line, and the feature-parity list was asked for before it was fully written. **Failure / learning line:** I had the data-parity contract written and the feature-parity contract only half written when a stakeholder asked for it; now a parity matrix — data and features — is the first artefact of any migration, before the schedule.

LP proof lines. Customer Obsession — the customer moved only when the new product was provably not worse on their own containers. **Have Backbone; Disagree and Commit** — argued against a blanket cancel; committed to each segment decision and ran the mechanics for all of them. **Success and Scale Bring Broad Responsibility** — competitors were cut with legal review and dated notice, not quietly; churn written into the record. **Earn Trust** — "I was input, not the decider; here is what was mine."

SAFE-SAY. Most attackable number: "Seventy-nine customers and about a hundred-and-eighty-six thousand dollars of annual revenue is the documented Crux base at the time of the decision — not a claim that we lost all of it, and not a saving." Source question: "The Crux customer transition RAPID — I have the latest version with the decision per segment and the dated cancellations — plus the pilot roll-out schedule and the product testing approach that carry the parity gate and the shadow accounts."

20-SECOND VERSION

We were retiring an acquired tracking product with seventy-nine paying customers. The product call was who to carry over: importers and exporters moved to the new product behind a gate that said the data had to be at least as accurate as the old one on their own containers; brokers were offered a partner path, forwarders the API, and two competitor platforms were cancelled after legal review. We walked away from three-quarters of the volume on purpose.

PROBING Q&A

You walked away from most of the volume. How is that customer-obsessed?

Because those were customers of the product we were retiring, not of the one we were building: truck brokers tracking non-Flexport containers and software platforms re-selling our data. The customer-obsessed act was offering each a real path — a partner arrangement in our trucking product, the API — and dated notice, rather than a quiet degrade. The importers who were our customers got a parity gate and a shadow account before they were asked to move.

What was your decision and what was someone else's?

Someone else's: the segment decisions — Recommend was product, Decide was the executive; I was input. Mine: the migration plan tied to the pilot waves, the "at least as accurate as Crux" gate, the shadow-account method and the production test account with its kill switches. If you ask who could have stopped a migration on data quality, that was me.

How did you communicate the retirement to a customer being cancelled?

Through the RAPID's inform-and-commit steps — the account owner carried the message, with a date and, where it applied, an alternative. I will not claim I wrote the customer letters; I can tell you the dates are in the record: August 1, September 1 and October 24, 2022 for the three cancel-now accounts.

What would you do differently?

Write the feature-parity matrix first, with a column per segment, and put the cost of keeping Crux alive on the same page. Two stakeholders asked for exactly those two things in the RAPID, and the fact they had to ask is my miss.

V3 · “One promise per customer, in both countries” — the UDC / Canada material as a product story (POINTER, not rewritten)

Where it lives: /workspace/amazon/panel/amazon-nacf-udc-canada-story-pack-star-kimi-k3.html — section **B4 · VENKATA** (full STAR, 60-second pitch, who-I-needed table, trade-off, LP proof lines, SAFE-SAY, 20-second version, four probes). Read it from that file; do not retell B1–B3 (Rocky/James variants) to Venkata.
When to use it: if he asks for a second product story, a “what did you choose not to build” example outside Flexport, or a customer story in a physical operation (closest to FBA). It is also the lived analogue for P1 below.

30-SECOND BRIDGE INTO B4 (SAY THIS, THEN TELL B4)

“At Sephora the product problem was the same sentence in two countries: the customer was being promised from the wrong place. In Utah a store and a dotcom shopper could want the same unit in the same building and get two different answers; in Canada a store's newness waited on a US warehouse picking it store by store. I treated both as product work — forty-four requirements ranked so the go-live set was the minimum that made one promise true, with history conversion, reserve-math changes and a reporting rebuild explicitly not built; and in Canada an existing cross-dock path reused, twenty small brands first, ten weeks of supply moved ahead so no store went dark.”

Facts to keep straight (from the UDC pack; do not improvise): two go-lives, zero customer-facing incidents (record); +15% processing efficiency is DC Ops' measurement (record); 44 requirement rows, three reserve buckets (Dotcom / Retail / Uncommitted — not nine); seven system families, about two dozen named systems; the FSD was planned Jul 26 and signed Aug 14 — never “held to the day”; Canada: about 13% of volume, pilot of 20 omni brands (about 217,000 units, 671 SKUs), waves 20 / 40 / 39, about 2.5M units front-loaded — **the plan at discovery exit; post-launch outcome VERIFY**. Failure line for B4: the analyst was a customer I under-served — interim reporting got a workstream in month three instead of day one.

P1–P4 · Product-sense add-ons (short STAR-backed answers)

Each is a 45-to-60-second answer with S/T/A/R labels, a trade-off, a failure/learning line and the number it lands. P3 uses the Crux retirement under the “what not to carry over” angle because no source offers a cleaner sunset the other packets have not already claimed (UDC 801/800 decommission belongs to the UDC pack; the manual WBR retirement is S16 in the extra-stories file).

P1 · “Tell me about something you decided NOT to build.” — the public tracking website and the charging plumbing

S. February 2022, Shipment Visibility was in pilot with a waitlist from FORWARD and an E-Team keen on a public container-tracking website to pull in SMB demand and cut acquisition cost. At the same time there was a request to build source-toggling and usage auditing so visibility could be charged for later. **T.** Help the product DRI and the E-Team decide what the small team would and would not build in the next two quarters. **A.** I put the goals in order with data from the pilot: Goal 1 was lower cost to serve and data quality — the thing pilot customers were actually complaining about; Goal 2 was a lead funnel. The E-Team wrote it down: “we prioritise (and cannot be distracted from) Goal 1”; the public website would wait for a PR-FAQ and a market where we already had coverage; the charging plumbing was deferred until additional data sources arrived. In parallel I chose not to make the 3PL ingestion test measure performance or cost to serve — two explicit non-goals so the test stayed small. **R.** The team's capacity went to POD-ETA accuracy and interaction elimination — the first two numbers on the weekly review — and to the automation that took cost to serve from $0.66 to $0.03 a container (record). The website became a PR-FAQ, not a build. **Trade-off:** slower SMB funnel against a product that was accurate first. **Failure /**

learning line: the thing I *did* under-build — monitoring — cost more than the things I correctly declined; "not building" has to include a list of what must still be built.

Probe: wasn't the public website a cheap way to get the volume you said you needed for data quality?

Yes — and the E-Team said exactly that, which is why it was a two-way door we kept open with a PR-FAQ rather than a no. My position was sequencing: get the production 3PL test account first — three hundred containers under our control — before inviting the public to judge coverage we knew was uneven.

P2 · "How do you tell adoption from usage from outcome?" — three ladders, and the one I got wrong first

S. Early in the pilot the number everyone quoted was customers on the platform; a customer who had logged in once counted the same as one tracking three hundred containers a week. **T.** Define success so that adoption could not masquerade as outcome, and so a weekly review could steer. **A.** I separated three ladders and gave each a gate. **Adoption:** customers onboarded — with a 50-container calibration bar before anyone was counted. **Usage:** monthly active users, containers uploaded (≥ 100 to graduate), key features tried (dashboard, shipment list, details, reporting, messaging). **Outcome:** what the customer and Flexport paid for — verification SLA met 90% of the time, data at least as accurate as the legacy product, cost to serve per container, automation rate. Ticket volume and response were tracked as a cost-of-quality line, not as "engagement." The weekly review was built input-to-output, red/green at ±5%, in the format borrowed from an existing operating review. **R.** Adoption 7 → 68 customers, 9.7× (record); usage 170 monthly active users — the public target, landed (record); outcome $0.66 → $0.03 per container, about 95%, automation 40% → 90%, ticket response 72% → 90% at five times the volume (record). **Trade-off:** three numbers are harder to headline than one; I accepted a slower story for an honest one. **Failure / learning line:** I conflated adoption with success for the first wave — a customer that uploaded a handful of containers was a "win" on my slide; the 100-container usage gate exists because of that slide.

Probe: which of the three would you cut if you could keep one?

Outcome — cost to serve per container with the accuracy gate attached. Adoption without it is a free product; usage without it is a busy one. But I would not report outcome without the other two, because the day a 99.4% week turned out to rest on three manual touches, it was the usage and touch counts that caught it.

P3 · "Tell me about a time you sunset something." — what we refused to carry over from Crux

S. Crux, the acquired tracking app, had 79 paying customers and features the new product did not: tracking of non-Flexport containers for trucking partners, and an open door for software platforms and brokers to pull our milestones. **T.** As owner of the migration mechanics, make sure what we carried over was chosen, and what we did not was said out loud with a date. **A.** I framed the sunset as a carry-over list rather than a shutdown list. Carried: container tracking by CSV and API, milestone display, reporting — behind a gate that the data be at least as accurate as Crux on the customer's own containers, proven in shadow accounts first. Not carried: non-Flexport tracking inside the trucking product ("we will not do so at this time" — decision), a standalone service for motor carriers and brokers (strategy doc), data access for the two SCM-SaaS competitors (cancelled after legal review). Cancellations dated: August 1, September 1, October 24, 2022 (record-from-docs). **R.** 55 importer/exporter customers in the transition segments; 24 in redirect-or-cancel, carrying about three-quarters of the 294,581 containers — volume we gave up on purpose. **Trade-off:** revenue and volume against a product with one target customer. **Failure / learning line:** the feature-parity list was asked for in the decision record before it was fully written; I now treat a sunset as a product launch with a parity matrix as its first artefact.

Probe: what would you have carried over if you had had another quarter?

Non-Flexport container tracking for partners who move our freight — the one truck broker already on Transmission is the proof there was a real customer. I would have scoped it as a partner tier of the same visibility service, not as Crux kept alive. It was the right thing to defer and the wrong thing to forget.

P4 · “Tell me about a conflict between a customer's ask and the platform roadmap.” — the truck brokers who wanted to keep tracking everything

S. The two largest Crux customers by far were truck brokers — the segment carried $139,512 of the $185,892 ARR and 221,044 of 294,581 containers (record-from-docs). Their ask was simple: keep letting us track every container, ours and everyone else's, the way Crux did. The roadmap said Shipment Visibility was for importers and exporters, and the trucking product, Transmission, would not add non-Flexport tracking now. **T.** Give the decision-makers an honest view of the conflict and a transition path that was not just “no.” **A.** I made sure the input on the record included the full picture: one broker was already a Transmission partner and should keep visibility; one was a large destination-management competitor who also sat inside a six-hundred-truck drayage company we wanted a relationship with; one was in the full-truckload space with no partnership. I argued against treating them as one segment and for a path each could actually take: white-label through Transmission like an existing partner, with the limit stated plainly — no non-Flexport containers — and cancellation at wind-down only if they declined. The pilot-schedule gate meant any importer customer they introduced would still go through the same parity bar. **R.** Decision: transition the two named brokers to Transmission partners, cancel at wind-down if not interested; motor carriers cancelled at wind-down; the capability to track non-Flexport shipments in Transmission explicitly deferred (record-from-docs). **Trade-off:** the largest revenue line against roadmap focus; we chose focus and said so with a date. **Failure / learning line:** I did not have the cost of keeping Crux alive for them on the same page as the decision — a stakeholder had to ask — so the “no” looked more arbitrary than it was.

> **Probe: the customer was paying you. Why does the roadmap win?**
>
> Because a product that serves the customer it was not designed for degrades for the customer it was. Our data quality bar was set for importers' containers on specific lanes; a broker tracking everyone's freight would have dragged coverage and cost to serve back toward the human-powered product we were retiring. The right answer to a paying customer outside your segment is a path and a date, not a quiet yes.

VERIFY list and short source trace

VERIFY — FACTS IN NO SOURCE, EACH WITH THE SAFE SENTENCE

ITEM	SAFE SENTENCE
My authorship of a written Crux-vs-SV feature-parity matrix	“The data-parity gate is in the pilot schedule in my words; the feature-parity list was asked for in the decision record and I will not claim I authored the final version.”
Final count of Crux customers migrated by end-2022; cost of keeping Crux alive	“The decision and the segments are documented; the December 2022 tally and the keep-alive cost are not in my files, so I won't quote them.”
“50% reduction in time to resolve blocker bugs” after the trace-id change	“My note at the time said about half; treat it as my estimate — the record says bugs went from hours to locate to traceable per system.”

Integrity: no inflated customer multiplier (9.7× only), no “$1.00 → $0.03” as a headline, no “achieved 32,000”, no savings claimed from the Crux ARR or the 2021 plan's $3.22M; James's A4 analytics (normalised reliability comparison) and Rocky's cutover runbook are not retold here.

PART 5 — VENKATA JOSYULA — PRODUCT + BEHAVIORAL

Venkata Josyula — Principal PM, FBA; Bar-Raiser style

Friday, October 30, 2026 · 12:00 PM PDT

Use: Six lived STAR stories with a product/customer lens. Answer the LP asked, distinguish what I owned from what engineers or operators owned, land one basis-labeled number, then stop. The failure answer is G1.

Contents

1 · S14 — Tell the customer first
~200 orders · $2.5M of order value · $10M initiative won

2 · S16 — Four systems into one pipeline
Accuracy 60% → 90% · value priced, not realized savings

3 · S9 — Scale by value
A thousand-lane program · 25 locations · 597 carrying 80% of spend first

4 · S13 — Cyber Monday at 4 AM
99% fill · about $8M of that day's sales protected

5 · I1 — LLM triage agent
$25 → $0.40 per incident · 98% cut · 100% citations

6 · G1 — The UAT that crashed
5 users × 10 scenarios passed · all-user concurrency failed two days before sign-off

Number discipline. S14's dollars describe order value and an initiative won. S16's annual figure was a BRD price, not a realized saving. S13's figure is protected sales, not savings. I1 was an independent build, not an employer deployment.

Product answer spine. Customer pain → observable metric → decision and rejected option → adoption/control → outcome → scar. For every "we," be ready to name my artifact, my call, and the team's work.

Sources: Amazon master S9/S13/S14/S16; Apple PM III workbook v11 F1/M1/I1/G1/A3/G3; NUMBERS-RECON CANON v2; Apple delta add-on. No Shipment Visibility, Crux, or answer bank included.

1 · S14 — Earn Trust: tell the customer first

MANHATTAN CUSTOMER TRUST Headline: about 200 orders and $2.5M of *order value*; the $10M initiative was won, not saved. user anchor

LPs: Earn Trust — I disclosed before correcting. · Customer Obsession — the customer set repair priority. · Have Backbone; Disagree and Commit — I challenged the quiet fix, then ran the chosen path. · Ownership — I put my labor behind the transparent option.

60-SECOND PITCH

"Two days before an executive review at a Manhattan customer, OMS and WMS disagreed on about 200 orders representing $2.5M of order value. A $10M initiative also rode on the review, and my manager favored correcting the data quietly. I built a discrepancy census by cause, explained that an unverified cross-table script could turn a data defect into a trust failure, and offered to run the war room myself. We told the customer first, gave them the affected list, and let them prioritize what mattered to their business. The consultants then used a reversible per-line patch with before-and-after evidence while engineering fixed the handshake. The discrepancy went to zero, the initiative was won, and the reconciliation report became a standing control. The $2.5M was order value and the $10M was initiative value—neither was savings. I learned that courage is not the durable mechanism; early, customer-visible reconciliation is."

S I found an OMS-to-WMS mismatch two days before a customer executive review: about 200 affected orders and $2.5M of order value. The room feared disclosure could jeopardize a $10M initiative.

T I had to protect the customer's order priorities and the relationship while getting the data consistent before the review.

A I sampled and reason-coded the affected population before advocating a path. I told my manager privately that a silent script could not be verified in two days and would create audit and reputation risk. I offered to own the war room. After he agreed, I took the list, cause, plan, and timeline to the customer before the review. They ranked the repair order; the consultants traced the handshake and executed reversible, per-line patches with evidence. I instituted a daily reconciliation report while engineering removed the defect class.

R I drove the affected set to zero with the team; the customer's highest-priority orders moved first; the $10M initiative was won; and the standing report showed zero new discrepancies. user anchor

WHO I INFLUENCED. I influenced my manager by framing the choice as comparative risk and putting the execution cost on myself; I influenced the customer by leading with the complete bad-news list and ceding repair priority to them; I aligned consultants and engineering on evidence per line.

TRADE-OFF I MADE. I chose transparent, customer-ranked repair over a faster silent correction. It cost a war room and exposed us before the review, but rejected an unverifiable script and preserved the customer's right to decide what mattered.

Failure / learning. We detected the mismatch too close to the review. I learned to make reconciliation a standing customer control, not an act of last-minute courage.

SAFE-SAY: "About 200 orders representing $2.5M of order value were made consistent in the open; the $10M initiative was won at the review and is not a savings claim."
If asked for source: "Those are user-anchor figures from my earlier story record; the nouns are order value and initiative value."

20-SECOND VERSION

"When OMS and WMS disagreed on about 200 orders and $2.5M of order value, I rejected a quiet fix, told the customer first, and let them prioritize repairs. The discrepancy went to zero, the $10M initiative was won—not saved—and customer-visible reconciliation became the standing control."

S14 · Four bar-raiser probes

Product/customer framing. The “product” was not the patch. It was a trustworthy recovery experience: disclose the affected population, give the customer control over priority, preserve reversibility, and prevent recurrence with a visible metric.

1. Why not fix it first and tell the customer after?

That would optimize our discomfort, not their outcome. We could not know which orders carried the greatest business consequence. Disclosure changed the repair sequence, so it was operationally better as well as more trustworthy.

2. How did you disagree with your manager without moralizing?

I acknowledged the legitimate fear of losing the initiative, brought a cause-based census, compared the audit and verification risk of both options, and volunteered to run the more expensive path. I challenged the risk assumption, not his integrity.

3. What did you personally do versus the team?

I built the census, made the risk argument, created the customer pack, won the disclosure decision, and ran the war room. Consultants traced and patched order lines; engineering built the permanent handshake fix. I do not claim their code.

4. What evidence says trust improved?

I do not claim a satisfaction score. The evidence is behavioral and operational: the customer reprioritized with us, the review proceeded with facts exposed, the initiative was won, and the relationship accepted a standing reconciliation control.

Bar-raiser close: “The uncomfortable meeting was not the result. The result was that the next discrepancy could not hide.”

2 · S16 — Four systems into one governed pipeline

FLEXPORT PRODUCT OPERATING SYSTEM Accuracy 60% → 90%; four systems → one pipeline; annual value priced, not realized savings. record

LPs: Ownership — I removed my own bus-factor risk and owned the security miss. · Invent and Simplify — seven governed metrics replaced four manual pulls. · Dive Deep — I exposed the missing join key and ticket-sync loss. · Frugality — I required unit economics before prioritization.

60-SECOND PITCH

“At Flexport, the Monday operating review depended on me stitching four systems together manually. Accuracy was 60%, tickets had no container join key, and the product had a bus factor of one. I wrote the BRD, froze seven metric definitions, specified a daily or hourly pipeline with failure alerts, and set cutover at less than 1% variance for consecutive weeks. Engineering built the ETL-to-Snowflake path; I owned requirements, parity, and cutover. The BRD priced the old process at $103,680 annually on its assumptions—30 hours a week across two reviews at an assumed $90 an hour—so I call that priced value, not savings. Mid-build I discovered I had omitted the customer-data security review. I owned the two-week miss the same day and kept every Monday review alive on the manual path. Accuracy rose from 60% to 90%, and the new alerts caught an approximately 4% ticket-sync drop that the old process missed. My permanent kickoff question is: whose approval does this data need, and what is its lead time?”

S I was the single point joining four disconnected systems for a VP’s Monday review. Accuracy was 60%, ticket records lacked a container ID, and silent data loss was possible.

T I had to turn a manual report into a reliable product without changing definitions during the build or skipping the weekly decision cadence.

A I froze seven definitions with owners, documented the missing join, wrote feed and alert requirements, and published a parallel-run gate: each metric within 1% for consecutive weeks. I used a cross-reference table as an interim bridge while pushing a real key upstream. Engineering built ETL → S3 → SQS → Snowflake → Looker. When the security review surfaced, I re-sequenced non-sensitive work, disclosed my planning miss, and retained manual rollback until access and correctness gates both cleared.

R I cut the review over from four systems to one pipeline; WBR accuracy moved 60% → 90%; the bus factor expanded beyond one person; no Monday review was skipped; and alerts found an approximately 4% sync drop. The BRD’s $103,680 was priced value on assumptions, not realized savings. record

WHO I INFLUENCED. I got metric owners to sign stable definitions, infrastructure to prioritize from a quantified BRD, Support to add a durable join key, Security to define the access gate, and the VP to switch only after parity evidence.

TRADE-OFF I MADE. I kept the labor-intensive manual path for two extra weeks and rejected premature cutover. That spent schedule margin but protected both access integrity and the Monday customer decision.

Failure / learning. I discovered the security review mid-build. The parallel run saved delivery, but partly by luck; security ownership and lead time now enter every data BRD at kickoff.

SAFE-SAY: “Accuracy moved from 60% to 90%; the BRD priced the baseline at $103,680 a year on stated assumptions—priced, not a claimed saving.”
If asked for source: “Apple A3/G3 and the Zendesk-to-Snowflake BRD; the BRD assumes 30 hours a week at $90 an hour, falling to six.”

20-SECOND VERSION

“I replaced a four-system, bus-factor-one review with a governed pipeline and a sub-1% parity gate. Accuracy moved 60% to 90%. I also missed the security review by two weeks, owned it immediately, kept the manual path alive, and made access lead time a permanent kickoff control.”

S16 · Four bar-raiser probes

Product/customer framing. The user was the VP making rollout decisions; the product contract was stable definitions, timely data, failure visibility, and evidence that the new source matched the old before migration.

1. Why is this product work rather than reporting automation?

I defined the user decision, frozen metric contract, trust gate, failure behavior, rollback, and operating ownership. Automation was the implementation; reliable decision-making without one person was the product outcome.

2. What exactly was the annual value?

The BRD priced the baseline at $103,680 annually using 30 hours a week across two WBRs at an assumed $90 an hour, versus six hours after. It was a prioritization model, not a realized or finance-booked saving.

3. Why accept only 90% accuracy?

That was system accuracy on the operating measure, not the parity cutover criterion. Cutover required each frozen metric to agree within 1% for consecutive weeks. I kept the distinction between product KPI and migration gate.

4. What was your hardest ownership moment?

Telling leadership the security gap was mine, not Security's delay. I had scoped correctness and omitted approval lead time. I brought the revised date, preserved Monday path, and checklist change in the same conversation.

Bar-raiser close: "A pipeline is not trusted because it runs; it is trusted because definitions, access, parity, and failure behavior are explicit."

3 · S9 — Scale: a thousand-lane program, 597 first

ELEMENTUM SCALE WITH RESPONSIBILITY A thousand lanes were asked across 25 European locations; 597 carrying 80% of spend went first. user anchor for 597/80%

LPs: Think Big — I kept the thousand-lane destination. · Have Backbone; Disagree and Commit — I re-scoped the first release two levels up. · Highest Standards — every cohort faced a 95% completeness toll. · Success and Scale — the long tail stayed inside the standard.

60-SECOND PITCH

"At Elementum, a strategic customer asked us to onboard a thousand freight lanes across 25 European locations in two months. Baseline completeness was about 60% against a 95% bar, so putting all lanes through at once would create a large, untrusted product. I pulled the routing guide and invoice history, ranked every lane by spend, volume, product criticality, and mode, and proposed that 597 lanes carrying 80% of spend go first. I took that re-scope two levels up with Transportation and Procurement validation. Every cohort faced the same toll: origin, destination, mode, carrier, rate, and transit time complete, followed by first tenders matching the guide. Overrides required reason codes. The first 597 created the business proof while the remainder followed behind the same gate across the thousand-lane program. Completeness moved from about 60% to 95%. I learned that scale is not counting rows launched; it is preserving trust as the long tail arrives. I would instrument tender acceptance from cohort one, not cohort three."

S At Elementum, I led a thousand-lane track-and-trace program requested across 25 European locations on a fixed window; source-data completeness was about 60%.

T I had to produce useful scale quickly without allowing dirty lanes to make the routing product confidently wrong.

A I ranked all requested lanes by spend, volume, criticality, and mode. I proposed 597 carrying 80% of spend as the first value cohort and took the decision two levels up. I created a lane-quality toll on six engine-read fields, required first tenders to match the guide, and ran one scorecard for completeness, acceptance, and on-time delivery. I preserved planner overrides only with reason codes so exceptions improved the product.

R I launched the 597 lanes carrying 80% of spend first within the thousand-lane program across 25 locations; completeness rose about 60% → 95%. The first wave carried the proof while the long tail remained governed. record: program/25/60→95 user anchor: 597/80%

WHO I INFLUENCED. I influenced the Global Head two levels up with the spend curve; Transportation and Procurement validated value and contract data; lane owners became cohort champions; resistant planners received an explainable override path instead of a mandate.

TRADE-OFF I MADE. I rejected equal-speed onboarding of all lanes and chose value-first waves. The long tail waited, but the customer saw trustworthy coverage where the business impact was concentrated.

Failure / learning. Tender acceptance was measured only from cohort three. I would instrument it in cohort one so a carrier-data issue cannot survive two extra waves.

SAFE-SAY: "It was a thousand-lane program across 25 European locations; 597 lanes carrying 80% of spend went first, and every wave faced the 95% completeness bar."
If asked for source: "The program scale and 60-to-95 result are in Apple F1/resume; 597 and 80% are user-anchor figures from my earlier program record."

20-SECOND VERSION

"A thousand lanes were asked across 25 European locations. At 60% completeness, I took a re-scope two levels up: 597 carrying 80% of spend first, every cohort behind a 95% data toll. We reached the quality bar without teaching users to distrust the product."

S9 · Four bar-raiser probes

Product/customer framing. The lane was the unit, but planner trust was the adoption problem. Value phasing supplied early proof; the quality toll protected the experience; reason-coded overrides converted local knowledge into product data.

1. Why 597, not 600 or the full thousand?

I did not choose a round target. I ranked the requested population and the Pareto break landed at 597 lanes carrying 80% of spend. The first-wave number followed value concentration.

2. Did the thousand lanes all go live?

The safe statement is that this was a thousand-lane program and 597 went first. Sources differ on the delivered-count wording, so I do not collapse “asked,” “first,” and “eventually onboarded” into one claim.

3. How did you handle a lane owner who knew the guide was wrong?

I allowed an override with a reason code. A specific exception could be correct; a silent workaround could not improve the system. We corrected the lane and retained the signal.

4. What broad responsibility came with scale?

Small carriers and low-spend lanes still faced the same validity standard. Prioritization changed sequence, not quality. I would not make long-tail users absorb bad data so the headline count looked larger.

Bar-raiser close: “The re-scope made the first promise smaller so the eventual product could be larger and trusted.”

4 · S13 — Cyber Monday: protect the promise first

MANHATTAN INCIDENT PRODUCT 99% fill; about $8M of that day's sales protected. record

LPs: Customer Obsession — I ranked orders by promise at risk. · Bias for Action — I made a reversible call before the full picture arrived. · Ownership — I signed the incident log and communicated through close. · Deliver Results — fill held at 99%.

60-SECOND PITCH

"At 4 AM on Cyber Monday, backorder lines were rising even though inventory existed across three DCs serving about 100 stores. About $6M was on the line when the page fired. I ran one bridge, one decision log, and traced the signal beyond the noise. The room assumed capacity; the allocation scheduler had actually stopped silently after a daylight-saving change. I triaged by customer promise at risk, rebalanced allocation across DCs, confirmed the plan with the business team, restarted the scheduler, and sent order-status updates every two hours through 9 PM. Fill held at 99%, and about $8M of that day's sales was protected. That is protected sales, not savings. The permanent product work mattered more: a scheduler heartbeat made silence the alarm, a daylight-saving checklist was added, and the rebalance playbook was rehearsed. My miss was paging the on-call engineer later than I should have while carrying the first stretch myself. The next peak was boring—and boring was the reliability outcome."

S I owned holiday ecommerce monitoring when an allocation backlog grew at Cyber Monday peak despite sufficient inventory across three DCs. My reason-coded alert fired at 4 AM; about $6M was on the line at that point.

T I owned holiday ecommerce monitoring and had to protect customer promises before complete diagnosis arrived.

A I created one bridge, log, and decision list. I traced inventory sufficiency and queue behavior to a scheduler that had stopped silently after daylight-saving time. I chose reversible manual rebalancing by promise at risk, coordinated restart with engineering and the client business team, and reported orders at risk, orders recovered, and clearance time every two hours. In the post-mortem I converted the absence of a scheduler heartbeat into an alert and added the checklist and playbook.

R I helped hold fill at 99% and protect about $8M of that day's sales; the next peak ran without the incident class. record

WHO I INFLUENCED. I aligned the client business team on promise-first triage, directed the cross-DC allocation sequence, gave engineers a reproduced failure instead of a capacity theory, and kept leaders aligned through plain two-hour updates.

TRADE-OFF I MADE. I chose a reversible, manual rebalance over waiting for an elegant automated diagnosis. It was deliberately unscalable for the night; the scalable heartbeat and playbook came through the post-mortem.

Failure / learning. The daylight-saving control should have existed before peak, and I should have paged the on-call engineer sooner rather than carrying the first stretch alone.

SAFE-SAY: "About $6M was on the line when the page fired; fill held at 99%, and about $8M of that day's sales was protected—protected sales, not savings."
If asked for source: "Apple M1 pages 40–41 and the resume; the final protected-sales noun resolves the source wording."

20-SECOND VERSION

"At 4 AM Cyber Monday, a silent scheduler stopped allocation. I rebalanced three DCs by promise at risk, ran one bridge and log, and held fill at 99%, protecting about $8M of that day's sales. The post-mortem made silence itself the alarm."

S13 · Four bar-raiser probes

Product/customer framing. Incident response is part of the product: observable failure, a reversible customer-priority action, truthful communication, and a post-incident control that removes dependence on heroics.

1. What did you personally decide at 4 AM?

I chose promise-at-risk as the triage order, authorized the cross-DC rebalance sequence with the business team, maintained the decision log, and set the two-hour executive update. Engineers restarted and repaired the scheduler.

2. How can protected sales exceed the amount initially on the line?

The approximately $6M was the exposure visible when the page fired. The approximately $8M was the final value of the day's orders protected across the failure window. They are different timestamps, not an arithmetic conversion.

3. Why did the system need a human?

On that night, the system we had was silent. Waiting for a perfect automated response would break promises by breakfast. I used a reversible human action, then removed that dependence with a heartbeat and rehearsed playbook.

4. What would make you stop the manual rebalance?

If the queue stopped improving, inventory sufficiency changed, or a node approached its operating limit, I would halt and reassess on the bridge. Reversibility was part of choosing the action.

Bar-raiser close: "The heroics protected one peak; the heartbeat protected every peak after it."

5 · I1 — LLM triage agent with an eval contract

INDEPENDENT BUILD AI PRODUCT $25 → $0.40 per incident; 98% cut; 100% citation coverage. build record

LPs: Invent and Simplify — I routed classes instead of using one model. · Frugality — unit cost was a release KPI. · Dive Deep — historical outcomes became a versioned eval contract. · Ownership — I built the stack and operating rules end to end.

60-SECOND PITCH

"I independently built an LLM incident-triage agent and treated it as an operations product, not a demo. The naive path cost $25 per incident, and an uncited proposal forced the operator to repeat the work. I built a graded historical eval set before changing prompts or models and made it the release contract: every change had to keep the known past passing. I added one trust rule—no citation, no proposal—binding every action to ticket evidence and a runbook line. Then I measured cost by class, sent routine classifications to smaller models, and reserved expensive calls for the hard tail. Cost fell from $25 to $0.40 per incident, a 98% reduction, while accuracy held on the eval set and citation coverage reached 100%. The trade-off was routing complexity and eval maintenance, which I accepted for checkable quality and viable unit economics. My miss was allowing the early eval set to grow while prompts were being judged; now I freeze and version the baseline before the first experiment."

S I built a Python/FastAPI triage agent for operational incident queues. The naive system produced useful output but cost $25 per incident and could recommend an action without checkable evidence.

T I needed an operations-grade product: known quality held, every proposal auditable, and unit cost below one dollar—without representing it as an employer deployment.

A I graded historical incidents with known-correct outcomes, versioned the eval harness, and gated prompt/model/routing changes on regression results. I required ticket and runbook citations for every proposal. I segmented incident classes, proved small models on routine classes, routed uncertain cases to the expensive path, and reviewed accuracy, citation coverage, and unit cost in one pane.

R I reduced unit cost from $25 → $0.40, a 98% cut; held accuracy on the eval set; reached 100% citation coverage; and cleared the sub-dollar release bar. build record

WHO I INFLUENCED. This was an independent build, so I did not claim an enterprise rollout. The influence mechanism was product evidence: the eval report makes quality reviewable, citations make operator verification fast, and unit economics makes the scale decision explicit.

TRADE-OFF I MADE. I rejected one premium model for every incident and chose tiered routing. That added classification logic and eval upkeep, but protected hard cases while making routine work economically viable.

Failure / learning. Early prompts were judged while the eval set was still changing. I now freeze and version the baseline first so a "win" cannot come from moving the test.

SAFE-SAY: "This was my independent build: $25 to $0.40 per triaged incident, a 98% cut, with accuracy held on my eval set and 100% citation coverage."
If asked for source: "My build record as captured in Apple I1, pages 41–42—not an employer production claim."

20-SECOND VERSION

"I built an independent triage agent with the eval set first and one rule: no citation, no proposal. Tiered routing moved unit cost from $25 to $0.40, down 98%, while eval quality held and citations reached 100%."

I1 · Four bar-raiser probes

Product/customer framing. The operator's job is not "receive AI text"; it is reach a correct, checkable first action faster. The product metrics therefore travel together: eval accuracy, citation coverage, and cost per incident.

1. How did cost fall without quality falling?

Most incidents belonged to routine classes. I proved smaller models held on those classes against the same eval set, then reserved expensive calls for uncertain and hard-tail cases. The eval contract made cheaper routing testable rather than hopeful.

2. What does 100% citation coverage prove?

It proves every proposal had checkable ticket and runbook evidence; it does not prove every proposal was correct. Accuracy and citation coverage are separate gates because a well-cited wrong answer and an uncited right answer create different risks.

3. What would break at FBA scale?

Data boundaries, access approval, drift, eval-set ownership, latency, and human escalation become programs. I would start with shadow decisions, versioned slices by incident class, and a human approval gate until production evidence beats the baseline.

4. Why is this more than another LLM demo?

It has a contract and a balance sheet. Every change must keep known cases passing, every proposal must cite evidence, and every incident carries an explicit unit cost. A demo can impress once; these controls can govern a quarter.

Bar-raiser close: "The model was replaceable; the eval contract, citation rule, and cost curve were the product."

6 · G1 — FAILURE: the UAT that crashed

FAILURE STAR **ELEMENTUM** Five users × ten scenarios passed; all-user concurrency failed two days before sign-off. record

LPs: Are Right, A Lot — my initial judgment and reflex were wrong. · Earn Trust — I took the criteria miss to the sponsor as mine. · Highest Standards — load became a numeric gate. · Ownership — I changed the contract, not the explanation.

60-SECOND PITCH

"Two days before sign-off on an Elementum track-and-trace product, five key users had passed all ten end-to-end scenarios, so I declared UAT green. The sponsor then opened access to all users and concurrent logins crashed the system. My first response made the failure worse: I reran my scenarios, they passed, and I sent screenshots. I was defending my plan instead of reproducing the customer's shape. I reversed course, simulated all-user concurrency with engineering, told the sponsor the missing performance criterion was mine, and the team worked the fix around the clock. We missed sign-off and had to rebuild confidence. I permanently rewrote the UAT contract so every critical flow has numeric uptime, page-load, and concurrency entrance and exit criteria at the customer's user count, data volume, and network. Later, a Flexport launch had to prove 500 containers in 20 minutes at 99.6% connectivity before customer testing. The deepest lesson was not 'add load testing'; it was that technically true screenshots can still be useless when the customer experience says the opposite."

S I had declared UAT green after five key users completed ten end-to-end scenarios each, with sign-off two days away. Broader concurrent access then crashed the product.

T I owned readiness and had to restore service and trust after my success criteria omitted the customer's real operating load.

A I first repeated the same tests and sent passing screenshots—my failure. I then reproduced the customer's all-user shape, found concurrency as the root cause, and explicitly owned the implicit requirement I had missed. Engineering simulated load and fixed the product while I reset sponsor expectations. I rewrote UAT with numeric uptime, page-load, user-count, volume, and network gates published before testing.

R I missed the sign-off date and had to rebuild confidence. I turned the miss into a standing control: later launch proof required 500 containers in 20 minutes at 99.6% connectivity before customer testing. record

WHO I INFLUENCED. I moved the sponsor conversation from blame to an owned criterion gap, focused engineering on reproducible concurrent load, and changed future product and QA teams from scenario-only testing to customer-shape gates.

TRADE-OFF I MADE. Once diagnosed, I chose transparent missed sign-off and round-the-clock remediation over relaxing performance expectations. It spent schedule and team capacity but did not ask the customer to accept an unproven product.

Failure / learning. My worst action was the defensive screenshot email. The first hour of an escalation now goes to reproducing the customer's shape, not proving our innocence.

SAFE-SAY: "Five users passed ten scenarios, but all-user concurrency crashed the system two days before sign-off; my criteria omitted load, and the sign-off date was missed."
If asked for source: "Apple G1, pages 43–44; later proof is Apple A5 and the Flexport program status record."

20-SECOND VERSION

"Five users passed ten UAT scenarios, but all-user concurrency crashed the product two days before sign-off. I first defended with screenshots—my mistake—then owned the missing load criterion. The date was missed; every gate I run now tests at the customer's shape."

G1 · Four three-level probe ladders + standing control

STANDING CONTROL CREATED. Every critical end-to-end flow now carries numeric entrance and exit criteria for uptime, page load, concurrent users, data volume, and the customer's network. Criteria are published before UAT and can stop sign-off. Later proof: 500 containers in 20 minutes at 99.6% connectivity before customer testing.

1. Why did you send screenshots?

Level 1: My scenarios genuinely passed, and I mistook coverage for truth.
Level 2: I optimized for defending the plan rather than learning why the customer could not work.
Level 3: The screenshots were technically true but decision-useless. Now the customer experience outranks my test artifact, and I reproduce their shape first.

2. Was the sponsor wrong to open access to everyone?

Level 1: No; they used the product as their work required.
Level 2: Their action exposed an implicit performance requirement that I failed to surface.
Level 3: Readiness ownership means converting foreseeable real use into written criteria; calling it "unexpected use" would preserve the defect in my process.

3. What did the failure cost?

Level 1: We missed sign-off and spent round-the-clock engineering effort.
Level 2: The larger cost was customer confidence; prior green evidence became suspect.
Level 3: I rebuilt trust by naming my criterion gap, showing reproducible load evidence, and giving the sponsor a gate that could stop us—not by asking them to trust another promise.

4. How do you know the learning stuck?

Level 1: UAT templates gained uptime, page-load, and concurrency thresholds.
Level 2: Tests run at customer user count, data volume, and network, not a lab approximation.
Level 3: A later launch required 500 containers in 20 minutes at 99.6% connectivity before customer testing. The lesson became a release control with evidence.

Product/customer framing. Scenario correctness answers "can the flow work?" Load readiness answers "can the customer work?" A launch product needs both.

Bar-raiser close: "I do not use the later success to erase the miss. I use it to prove the miss became a control."

Integrity check: six lived stories only. No design cases. Basis labels distinguish record, user anchor, and BRD pricing.

Part 5 — Venkata Josyula — STAR answer bank (product + behavioral, bar-raiser style)

Friday Oct 30, 12:00 PM PDT · Principal PM, FBA · the last interview of the loop · Amazon L6 Senior Supply Chain Manager, NACF

Rajesh Rishiyur Chandrasekaran · every answer is STAR, first person, with the number to land, what not to say, the source story and the likely follow-up. Product / customer angle only — Rocky got program and cutover, James got process and governance.

Contents

A · How to run this hour (cram) and the ten stories, three levels deep
B · STAR answer bank — 16 LPs × 2 real AIQB questions = 32 answers
C · NEW since this morning — 7 questions the hiring manager, Ryan and Rocky's six did not use NEW
D · Router — 16/16 LPs plus the nine non-LP prompts
E · Bar-raiser trap drills — the exact sentences
F · Questions to ask Venkata · G · Source trace · H · VERIFY with safe sentences

A · How to run this hour

Who he is. Principal PM in FBA, so he thinks about the seller as a customer, inbound trust, and mechanisms that scale. He is the bar raiser, so he will dig three levels into one story, separate *I* from *we*, and ask what failed. **My frame for him:** "I treat supply-chain programs as products: a named customer, a written problem, a ranked requirement list with a visible deferral list, a metric chosen before launch, and a gate held in public."

THREE OPENING SENTENCES (PICK ONE WHEN HE SAYS "TELL ME ABOUT YOURSELF")

- "I build the systems that decide what we can promise a customer — order allocation at Manhattan, visibility at Flexport, inventory and warehouse programs at Sephora — and I run them like products: customer, metric, gate."
- "The pattern in my work is that the customer was being promised from the wrong place, and my job was to make one true promise and prove it with a number we agreed before launch."
- "I am happiest when the deferral list is written down, the launch gate is published before the wave, and the review makes the decision instead of me."

THE FIVE NUMBERS NEVER TO GET WRONG

- **Shipment Visibility:** 7 to 68 customers, 9.7 times; cost to serve $0.66 to $0.03 per container, about 95%. Never round to ten times. record
- **Manhattan discrepancy:** about 200 orders, $2.5M of *order value*; the $10M is the *initiative won*, not savings. record
- **Snowflake pipeline:** four systems to one; WBR accuracy 60% to 90%; the status quo was *priced* at over $100K a year, not saved. record
- **EDI lanes:** a thousand lanes were asked; 597 carrying 80% of spend went first; completeness 60% to 95%. record
- **LLM triage:** $25 to $0.40 per incident, 98%, independent build — not an employer deployment. record

Freshness. The hiring manager heard Shipment Visibility from the operating lens and the Flexport FF App roadmap / cost-to-serve story; Ryan was routed through S9 among others. With Venkata, Shipment Visibility is told as a *product* (graduation criteria, the customer it protected, the flattering number thrown away), S12 only as the rebuild-or-reuse rule and partner adoption, and S9 only as the customer conversation and the small-carrier floor. If he says "I think you told

> my colleague this," say: "You may have heard the program; I'll give you the product decision inside it, which they didn't get."

The ten stories — the 20-second version, the trade-off, the failure line, three levels deep

Use each card when he digs. Level 1 is what I did; level 2 is how I knew; level 3 is what I would change or what proves it. Basis labels: **record** = Apple v11 / resume / master packet; **record-from-docs** = a page of a program document.

V1 · S11 — Flexport Shipment Visibility as a product: 7 → 68 customers behind six published graduation criteria

LPs Customer Obsession · Deliver Results · Earn Trust · Insist on the Highest Standards

20-second version. Leadership told me the visibility program was not showing value. I was program owner across nine teams and about a hundred people. I published six graduation criteria to Sales before wave one, held wave three in public on an ETA-accuracy miss from one bad source, and threw away a flattering 99.4% week. We went from 7 to 68 customers with zero rollbacks, and cost to serve fell from $0.66 to $0.03 per container.

TRADE-OFF I MADE. Sales wanted the whole pool boarded at once. I chose waves behind criteria, which cost us speed in the first two quarters; the VP still unlocked the 68-customer rollout two months early.

Failure / learning. I started the weekly review after the critique, not at kickoff. Next time the review starts on day one.

Three levels deep. L1: I wrote the seven metric definitions and the six graduation criteria. L2: the owner of each input — Data Services, Support, GTM — signed the definition they would be red against; a 300-container sample gave ±1.6% at 95% confidence. L3: what proves it held is that the customers we held in wave three became the cleanest wave.

SAFE-SAY. "Seven to sixty-eight customers is 9.7 times, and cost to serve per container went from sixty-six cents to three cents — about ninety-five percent." **Source?** "The State of SV and pilot roll-out documents, and the master packet's launch record."

V2 · Crux customer transition — 79 customers, a segment rule each, honest cancels

LPs Customer Obsession · Earn Trust · Are Right, A Lot · Have Backbone

20-second version. Flexport had acquired a visibility product, Crux, with 79 customers — $185,892 of ARR and 294,581 containers in 2021 — and the aim was to move them to Shipment Visibility by end 2022. Not every segment fit. The decision gave each segment a rule: shippers to Shipment Visibility, forwarders, customs brokers and 3PLs to the SV API with no extra dev, two brokers to a partner product, and the two competitor SaaS accounts cancelled on published dates.

TRADE-OFF I MADE. Building parity features for small segments versus a clean path or a clean cancel. The decision chose no extra build; the cost was some revenue and some goodwill in the long tail.

Failure / learning. The dissent in the document asked for the cost of keeping Crux running; that number should have been in the first draft, not requested by a reviewer.

Three levels deep. L1: the segment table — GKA 2, Enterprise 14, SMB 39 to SV. L2: the two brokers carried most of the volume, so they got individual calls; one relationship mattered because of a 600-truck drayage partner. L3: cancels dated August 1 and October 24, 2022 are the proof that the hard part was done, not deferred.

SAFE-SAY. "Seventy-nine customers, about $186 thousand of ARR — I do not claim any preserved-ARR number, because the document doesn't have one." **Source?** "The RAPID decision document for the Crux customer transition, the 2022 version."

V3 · S14 — Manhattan: the $2.5M OMS↔WMS discrepancy my manager wanted fixed quietly

LPs Earn Trust · Have Backbone · Customer Obsession · Bias for Action

20-second version. Two days before an executive review, OMS and WMS did not reconcile — about 200 orders, $2.5M of order value — and a $10M initiative rode on the review. My manager and the room favored a quiet back-end fix. I built the discrepancy census by cause, argued risk not virtue, offered to run the war room myself, and we told the customer first. The prioritized orders were patched line by line, and the initiative was won.

TRADE-OFF I MADE. Quiet script versus transparency. I chose transparency and put the cost — my time in a war room, my risk of being wrong in front of the customer — on myself.

Failure / learning. I should have proposed the standing reconciliation report before there was a crisis to justify it.

Three levels deep. L1: the census by cause and the options memo were mine; the consultants traced the handshake and wrote the patch. L2: a cross-table script written in two days had no rollback; per-line patching did. L3: the standing reason-coded reconciliation report, read before every executive review, is what outlived the war room.

SAFE-SAY. “The $2.5 million is order value in discrepancy; the $10 million is the initiative the customer awarded — I don't count it as savings.” **Source?** “My Manhattan consulting record, as captured in the master packet.”

V4 · S16 — Flexport: four systems into one Snowflake pipeline

LPs Ownership · Invent and Simplify · Frugality · Learn and Be Curious

20-second version. Our Monday review ran on four systems stitched together in Google Sheets by one person — me. Accuracy was 60%, tickets had no container ID, and a VP was steering on a number I could break. I wrote the BRD, priced the status quo at over $100K a year in the infra team's own rates, and held cutover to a parallel run within 1% for consecutive weeks. Accuracy went to 90%, and the first automated catch was a 4% ticket-sync drop nobody could see before.

TRADE-OFF I MADE. Build the pipeline before or after the rollout. I kept the manual pull running every Monday as the rollback rather than pause the review.

Failure / learning. I did not plan the data-access security review and it cost two weeks; I owned it upward the same day. (That miss is James's failure story — mention it in one line only.)

Three levels deep. L1: I wrote the BRD and owned cutover; infra built it. L2: the join gap — tickets without a container ID — was solved with a cross-reference table first, then a real key pushed upstream. L3: bus factor went from one to at least two, and the definitions now live in code.

SAFE-SAY. “The hundred thousand is a priced baseline in the infra team's own rates — it is not a savings claim.” **Source?** “The BRD for SV Zendesk data in Snowflake and the master packet's S16 record.”

V5 · S9 — Elementum: a thousand lanes asked, 597 built first

LPs Have Backbone · Customer Obsession · Insist on the Highest Standards · Success and Scale

20-second version. The customer's Global Head of Supply Chain wanted inbound visibility on a thousand lanes in two months; data completeness was 60% and the high-value lanes were blind. I built the spend Pareto — 597 lanes carried 80% of freight spend — pre-validated it with Transportation and Procurement, and took it two levels above my sponsor. I published a 95% valid-ASN gate and held a cohort twice when it failed on a timestamp format. Completeness reached 95%.

TRADE-OFF I MADE. All thousand lanes at once versus spend-weighted cohorts. I chose cohorts and an XML/portal floor so small carriers could stay in the standard; the cost was telling an executive no on lane count.

Failure / learning. Automating dirty data manufactures confident wrong answers; I would publish the gate even earlier, in the kickoff deck.

Three levels deep. L1: I owned the scope analysis and the onboarding standard; engineers built the maps. L2: the lane score was spend × criticality × mode × volume, and no lane owner could contradict the cut. L3: freight spend fell about 10%, roughly $2M in six months, and about 200 lanes followed behind the same gate.

SAFE-SAY. “A thousand lanes were asked; 597 carrying 80% of spend went first — that is spend share, not lane count.” **Source?** “The Elementum program record in the master packet, S9.”

V6 · S13 — Manhattan: Cyber Monday, 4 AM, the scheduler that died

LPs Bias for Action · Customer Obsession · Deliver Results · Dive Deep

20-second version. I was the OMS consultant on allocation and promising for a retailer with 3 DCs and 100 stores. At 4 AM on Cyber Monday the VP called: backorders piling up with inventory present, about $6M of sales at risk against a 95% fill goal. I ranked clears by promise at risk instead of first-in-first-out, rebalanced so no DC drowned, and logged every move. The root cause was an allocation scheduler that died silently at the daylight-saving change. We delivered 99% fill and protected about $8M of peak sales.

TRADE-OFF I MADE. Act before knowing the cause, or wait. I acted, with every rebalance reversible and timestamped.

Failure / learning. Nobody had written a clearing rule for failure — including me. Now the rule is written before the peak.

Three levels deep. L1: I owned the response and the post-mortem mechanisms; engineering fixed the scheduler once I isolated it. L2: the contradiction — available to promise above zero while backorders rose — was my evidence to declare an incident. L3: the heartbeat, DST checklist, 3σ page rule and rehearsed rebalance playbook meant the next peak ran boring.

SAFE-SAY. “About eight million of peak sales protected against about six million at risk — both are the record; any margin figure is my model.” **Source?** “My Manhattan consulting record in the master packet, S13.”

V7 · I1 — independent LLM triage agent: eval first, no citation no proposal

LPs Invent and Simplify · Frugality · Learn and Be Curious · Dive Deep

20-second version. I built an independent LLM triage agent for operational incident queues and treated it as a product, not a demo. The naive version cost $25 per incident and could answer without evidence. I graded historical incidents into an eval set, made it the release gate, required every proposal to cite the ticket and runbook, and routed easy classes to smaller models. Cost fell to $0.40 per incident, 98%, with 100% citation coverage and accuracy held on the eval set.

TRADE-OFF I MADE. One expensive model for everything versus tiered routing. I chose routing, which added complexity and eval maintenance.

Failure / learning. The early eval set grew while I was judging prompts; I would freeze and version the baseline before the first change.

Three levels deep. L1: I built the stack, the eval harness and the operating rule myself. L2: cost by class showed most incidents were easy; small models held on those against the eval set. L3: at FBA scale, access review, data boundaries and drift become programs of their own; I'd keep a human approval gate until production evidence beats the human baseline.

SAFE-SAY. “This was my independent build, not an employer production program.” **Source?** “My build records, captured in the Apple workbook, I1.”

V8 · G1 — Elementum: the UAT that crashed two days before sign-off (my failure)

LPs Are Right, A Lot · Earn Trust · Ownership · Insist on the Highest Standards

20-second version. Two days before UAT sign-off on an Elementum track-and-trace app, five key users had passed all ten end-to-end scenarios. Then the sponsor opened access broadly and concurrent logins crashed the system. My first move made it worse: I reran my scenarios and sent screenshots. I owned the miss to the sponsor, engineering simulated concurrency and fixed it, and I rewrote the UAT contract with numeric load criteria. The sign-off date was missed.

TRADE-OFF I MADE. Hold the sign-off date with a waiver, or miss it honestly. I chose to miss it rather than ask the customer to accept an unproven system.

Failure / learning. My failure was defensive diagnosis — I mistook my coverage for the truth. The first hour of an escalation now goes to reproducing the customer's shape.

Three levels deep. L1: I owned readiness and the criteria. L2: the requirement was implicit — users worked the way their job demanded. L3: the proof the lesson stuck is that my later Flexport launch gate was written in load terms before customer testing.

SAFE-SAY. “Five key users passed ten scenarios, but concurrent access crashed the system two days before sign-off; my criteria omitted load, and the deadline was missed.” **Source?** “Apple workbook G1, pages 43–44.”

V9 · UDC-B4 — Sephora: one promise per customer, in both countries (product lens)

LPs Customer Obsession · Invent and Simplify · Learn and Be Curious · Success and Scale

20-second version. In Utah a store and a dotcom shopper could want the same unit in the same building and get two different answers, because the building kept two books. I treated it as product work: one pool with two selling identities, the requirements ranked so the go-live set was the minimum that made one promise true, and a written list of what we would not build. Two go-lives, zero customer-facing incidents. For Canada, the plan reused an existing cross-dock path, twenty small brands first.

TRADE-OFF I MADE. Fewer features sooner with the deferrals written down — no history conversion, no reserve-math change. The cost landed on analysts, who lived with two systems of record for four months.

Failure / learning. The analyst was a customer I under-served; the interim reporting got a workstream in month three instead of day one.

Three levels deep. L1: I owned the requirement set and the customer outcome. L2: the issues log's own categories — 331 go-live, 77 fast-follow, 36 enhancement — are the record of the triage. L3: 85.4% of 836 issues closed and the rest owned; processing efficiency up 15% by DC Ops' measurement.

SAFE-SAY. “Thirteen percent is the Canada discovery deck's figure for US-managed store volume — the plan at discovery exit, not a measured outcome.” **Source?** “The July 2024 architecture-council deck, the June 2023 Canada discovery deck, and the program issues log.”

V10 · S12 (product-decision facet only) — Flexport FF App: the rebuild-or-reuse rule and partner adoption

LPs Think Big · Frugality · Customer Obsession

20-second version. The hiring manager heard this roadmap. For Venkata, tell only the product decision inside it: I wrote a per-module rule — anything over eight dev-weeks to rebuild gets reused — and chose partners as the first persona. The MVP went live with 11 partners in 10 countries, and 48 of 53 import partners migrated within a month. Operators stayed on old screens two more quarters, and we priced and published that cost.

TRADE-OFF I MADE. Partner-first versus operator-first. I chose partners, knowingly leaving operators on old screens for two more quarters.

Failure / learning. I would have written the reversal trigger into the first draft rather than the second.

Three levels deep. L1: I owned the sequencing recommendation; engineering re-estimated. L2: 20% of the work was still happening in the old app, which made reuse the cheaper path. L3: about $5M of cost avoidance is the record figure — I say it once.

SAFE-SAY. “About five million of cost avoidance — said once, never as an annual run-rate too.” **Source?** “The FF App high-level solution documents and the master packet S12.”

B · STAR answer bank — 16 LPs × 2 real AIQB questions

Each answer runs about 90 seconds aloud. Say the opener, then S, T, A, R in that order, then stop. Answers whose AIQB wording the hiring manager also used are marked in the note line; the story here is different, so it stays fresh.

B1 · Customer Obsession AIQB: Customer Obsession Q1 · story V3 · S14

“Describe a difficult interaction you had with a customer. How did you deal with it? What was the outcome? How would you handle it differently?”

Opener: “The hardest customer conversation I've had was one my own side didn't want to have — telling a customer, two days before their executive review, that our two systems disagreed about $2.5 million of their orders.”

S I was a consultant at a Manhattan customer. Two days before an executive review, OMS and WMS did not reconcile — about 200 orders, $2.5M of order value — and a $10M initiative rode on that review. My manager and the room favored a quiet back-end correction.

T I owned the recommendation and, once we chose, the war room.

A I built a discrepancy census by cause on a sample of the 200 so we argued facts first. I told my manager privately, then disagreed on risk: a cross-table script written in two days had no rollback, and an IT audit would turn a data issue into a trust issue. I offered to run the war room myself. I wrote the customer pack — root cause, plan, timeline, no apology-first — and sent it to their IT and finance before the review, not in it. They chose which orders mattered most; we patched those line by line with before-and-after evidence per order.

R The prioritized set reconciled to zero before the review, the handshake got a clean root-cause fix, and the customer awarded the $10M initiative. The reconciliation report became a standing control. Differently: I would have proposed that report before there was a crisis to justify it.

Number to land: about 200 orders, $2.5M of order value; $10M initiative won record · **Do not say:** “we saved $10M” — it is an initiative won, not savings; “the customer was angry” — they were not; they prioritized and gave us time
Likely follow-up: “What if your manager had said no?” — I would have written up the risk assessment and asked for the decision to be recorded with its owner, then committed — with the tripwire named: any audit query on those orders. I would not have run the silent script without that record.

B2 · Customer Obsession AIQB: Customer Obsession Q4 · story V1 · S11

"Give me an example of a time when you asked for customer feedback. How did you use that feedback to drive innovation or improvement? How did the customer respond?"

Opener: "The most useful customer feedback I've had came as a criticism of me: leadership said our visibility product wasn't showing value, and the real customers' feedback was hiding inside our own wave data."

S At Flexport I owned the Shipment Visibility launch across nine teams. Seven pilot customers were on it at $0.66 cost to serve per container; Sales wanted the whole pool boarded at once; leadership said the program was not demonstrating value.

T I had to turn customer experience into evidence that could steer the rollout, and board customers only as fast as the product could serve them well.

A I set a calibration entry bar of about 50 containers per client so each new customer's own data told us whether we were ready for them. I wrote six graduation criteria and published them to Sales before wave one. I froze seven metrics in a weekly review copied from an existing leadership review. In wave three the customer signal said ETA accuracy was off; I traced it to one bad data source and held the wave in public rather than give twenty-plus customers a bad first impression. We fixed the source, then boarded them.

R We went from 7 to 68 customers — 9.7 times — with zero rollbacks, and cost to serve fell from $0.66 to $0.03 per container, about 95%. The customers we held became the cleanest wave. The VP unlocked the full rollout two months early off the review.

Number to land: 7 → 68 customers (9.7×); $0.66 → $0.03, about 95% record · **Do not say:** "ten times"; "I invented the WBR" — I copied a trusted format
Likely follow-up: "How did Sales take the hold?" — They had the six criteria before wave one, so the hold was the rule firing, not my opinion. That is why I publish gates before the first wave — it turns a fight into a check.
Note. The hiring manager heard Shipment Visibility as an operating story; here the angle is the customer signal and the held wave.

B3 · Ownership AIQB: Ownership Q1 · story V4 · S16

"Tell me about a time when you took on something significant outside your area of responsibility. Why was it important? What was the outcome?"

Opener: "I wrote the requirements for a data pipeline no one had asked me to own, because a VP was steering on a number that only I could break."

S At Flexport the Monday review for Shipment Visibility ran on four systems that didn't talk, stitched together in Google Sheets by one person — me. Accuracy was 60%, tickets carried no container ID, and each snapshot took 1.5 to 2 hours.

T Data infrastructure was not my team. Nobody had written requirements for a program's operating metrics. I took the BRD and the cutover; the infra team owned the build.

A I documented the as-is and named the join gap. I priced the status quo at over $100K a year in the infra team's own loaded rates, so they prioritized it themselves instead of me escalating. I froze the scope to the seven metrics already in the review — nothing new. I set acceptance as a parallel run within 1% for consecutive weeks, and I kept running the manual pull every Monday as the rollback so the review never skipped a week. We used a cross-reference table for the ticket join first, then pushed a real key upstream.

R Accuracy went from 60% to 90%, the bus factor went from one to at least two, and the first automated catch was a 4% ticket-sync drop that had been invisible in the manual era.

Number to land: accuracy 60% → 90%; >$100K a year *priced* baseline record · **Do not say:** "we saved $100K" — it was a price on the status quo; "I built the pipeline" — infra built it
Likely follow-up: "What went wrong?" — I didn't plan the data-access security review; it cost two weeks. I told my manager the same day it surfaced and re-sequenced, and we skipped zero review deliveries. Every kickoff now asks whose approval the data needs and how long it takes.

B4 · Ownership AIQB: Ownership Q2 · story V8 · G1

“Describe a time when you didn't think you were going to meet a commitment you promised. How did you identify the risk and communicate it to stakeholders? Is there anything you would do differently?”

Opener: “Two days before a UAT sign-off I had promised, I learned my test plan had missed the one thing that mattered to the customer — and I made it worse before I made it better.”

S At Elementum I owned readiness for a customer's track-and-trace application. Five key users had passed all ten end-to-end scenarios; sign-off was two days away.

T Earn the sign-off, including requirements the written scenario list had not made explicit.

A When the sponsor opened access more broadly, concurrent logins crashed the system. My first reaction was wrong: I reran my scenarios, they passed, and I sent screenshots. Then I stopped defending the plan and reproduced the customer's actual shape — many users at once. I told the sponsor plainly that the gap was mine: their users had exposed a performance requirement I failed to surface. Engineering simulated the concurrent load and worked the fix while I rewrote the UAT contract with numeric uptime, page-load and concurrent-load criteria at the customer's user count, data volume and network.

R The sign-off date was missed and confidence had to be rebuilt. What changed permanently is that every critical scenario I own now has numeric entrance and exit criteria, including load at the customer's shape.

Number to land: 5 users × 10 scenarios passed; concurrency crashed it 2 days before sign-off; date missed record · **Do not say:** “the sponsor caused it by opening access” — their users behaved as their work required
Likely follow-up: “How did you communicate it?” — To the sponsor first, as my miss, with what we knew, what we didn't, and when they would hear next. Then to my own leadership with the same words. No screenshots the second time.

B5 · Invent and Simplify AIQB: Invent and Simplify Q3 · story V9 · UDC-B4

“Tell me about a time when you were able to make something simpler for customers. What drove you to implement this change? What was the impact?”

Opener: “At Sephora's Utah DC a store and a dotcom shopper could ask for the same unit in the same building and get two different answers — I made it one answer.”

S The building ran as two systemic warehouses — Dotcom and Retail — with duplicate receiving, split storage, internal self-transfers and two planning views.

T I owned the requirement set and the customer outcome: the minimum change that would make one promise true.

A I wrote the customer problem first: one inventory, one promise, two channels — a single location with the Dotcom selling location mapped onto it. I ranked the requirements with one test: does the customer's promise become false without this? Location setup, PO creation with channel reserves, the conversion script and the OMS source node passed. History conversion, reserve-math improvements and a reporting rebuild did not, and went onto a written deferral list. The issues log carried that triage in its own categories — 331 go-live, 77 fast-follow, 36 enhancement.

R Two go-lives with zero customer-facing incidents, and processing efficiency up 15% by DC Ops' own measurement. My miss: analysts lived with two systems of record for four months; the interim reporting deserved a workstream on day one.

Number to land: zero customer-facing incidents across two go-lives; +15% by DC Ops' measurement record · **Do not say:** “nine reserve buckets” — there were three; that it “held to the day” — design was planned for Jul 26 and signed Aug 14
Likely follow-up: “Why not convert history?” — It would have touched every downstream system's past rows for a benefit no shopper would feel. We copied forward only what planning needed — sales history and forecast — and wrote “no conversion of historical transactions” on the scope slide.

B6 · Invent and Simplify AIQB: Invent and Simplify Q5 · story V7 · I1

"Tell me about a time when you had a challenging problem or situation that the usual approach wouldn't address. How did you select an alternative approach? What alternative approach(es) did you consider? What was the end result? What was the impact?"

Opener: "The usual approach to an LLM product is to pick the best model and tune prompts; for an incident-triage agent that gave me good answers at $25 each with no way to check them."

S I independently built a Python/FastAPI triage agent for operational incident queues. The naive version produced useful proposals but cost $25 per incident and could answer without a checkable chain of evidence.

T Make it operations-grade: quality held on known cases, every proposal checkable, unit cost under a dollar — and not present it as an employer deployment.

A I considered three paths: one premium model for everything, prompt tuning alone, or treating it as a product with a quality contract. I chose the contract. I graded historical incidents with known-correct outcomes into an eval set and made it the release gate — every change had to keep the past passing. I added one rule: no citation, no proposal — each action bound to ticket evidence and a runbook line. Then I measured cost by incident class and routed routine classes to smaller models, reserving expensive calls for the hard tail.

R Cost fell from $25 to $0.40 per incident — 98% — with 100% citation coverage and accuracy held on the eval set.

Number to land: $25 → $0.40 per incident, 98%; 100% citations record · **Do not say:** "deployed at my employer"; "zero errors" — the claim is accuracy held on the eval set

Likely follow-up: "What would you do differently?" — My first eval set kept growing while I was judging early prompts, so early comparisons weren't clean. I would freeze and version the baseline before the first experiment.

B7 · Are Right, A Lot AIQB: Are Right, A Lot Q5 · story V8 · G1

"We don't always make the right judgment all the time. Tell me about a time when you made an error in judgment. What was the impact? What did you learn? How have you applied what you learned?"

Opener: "My clearest error in judgment was not the test plan I missed — it was the hour after, when I tried to prove I was right instead of finding out what the customer saw."

S At Elementum, two days before UAT sign-off on a track-and-trace app, five key users had passed all ten scenarios. The sponsor opened access broadly, and users said they could not complete a flow.

T I owned readiness; my job in that moment was to find the truth fast.

A My judgment call was to rerun my scenarios. They passed, and I sent the sponsor screenshots. That was defending my coverage. When it was clear users were still blocked, I reproduced their real shape — many concurrent logins — and the system crashed. I went back to the sponsor and said the gap was mine. Engineering simulated the load and fixed it; I rewrote the readiness criteria in numbers: uptime, page load and concurrent load at the customer's user count, data volume and network.

R The sign-off date was missed and trust had to be rebuilt. I've applied it since: in any escalation, the first hour goes to reproducing the customer's shape, and "works for us" is never readiness evidence.

Number to land: 2 days before sign-off; 5 users × 10 scenarios; date missed record · **Do not say:** a small or blame-shifting failure; "the system was fine, the users were wrong"

Likely follow-up: "How do you know the lesson stuck?" — My next major launch gate at Flexport was written in load terms — a volume of containers in a fixed time at a connectivity threshold — and passed before customers touched it.

B8 · Are Right, A Lot AIQB: Are Right, A Lot Q3 · **story V2 · Crux**

"Tell me about a time when you made a difficult decision with input from many different sources (customers, stakeholders, partner teams, etc.). What was the situation and how did you arrive at your decision? Did the decision turn out to be the correct one? Why or why not?"

Opener: "When Flexport retired an acquired visibility product, the hard part was not the migration — it was deciding, customer segment by segment, who we should keep and who we should honestly let go."

S Crux had 79 customers — $185,892 of ARR and 294,581 containers in 2021 — and the aim was to move them to Shipment Visibility by end 2022. Shipment Visibility did not fit every segment.

T I owned the Shipment Visibility side: which segments our product could serve without new build, and how they would board. The RAPID's recommenders and decider are named in the document. VERIFY my exact RAPID role

A The inputs pulled in different directions. One leader wanted Flexport to be the data authority — everyone on our milestones. Another asked for the cost of keeping two systems. A third wrote that ejecting customers is never a good experience and asked about feature parity and consignee timing. Account owners knew which brokers mattered: one held a national home-improvement retailer's account and was part of a 600-truck drayage company we wanted a relationship with. The decision became one rule per segment: shippers — GKA 2, Enterprise 14, SMB 39 — to Shipment Visibility; forwarders, customs brokers and 3PLs to the SV API with no extra dev, or cancel; two brokers to a partner product; the two competitor SaaS accounts cancelled.

R Every one of the 79 had a decided, dated path. The competitor accounts were cancelled on August 1 and October 24, 2022. I think it was right because no segment was force-fit into a product that didn't serve it.

Number to land: 79 customers; $185,892 ARR; 294,581 containers record-from-docs · **Do not say:** any preserved-ARR or churn number — the document has none

Likely follow-up: "Was cancelling paying customers customer-obsessed?" — Force-fitting a segment we didn't serve would have turned this year's revenue into next year's churn plus support cost. A clean cancel with notice and a path — the API or a partner product — kept it honest.

INTERVIEW-PREP PACKET 1 OF 5 · PER-INTERVIEWER · BUSINESS-PROCESS LENS · V2 — SEVEN FLEXPORT PRIMARIES

Amazon NACF Supply Chain loop — Packet 1: Snigdha Tripathy

Amazon — Senior Supply Chain Manager, NACF Supply Chain (L6)

Snigdha Tripathy

Senior Manager, Supply Chain — NACF Supply Chain · HIRING MANAGER

Wednesday, October 29, 2026 · 10:00 am PDT · 55-minute video interview

Strategy in one line. The hiring manager judges fit for the actual work — and her public profile (EU inventory-placement strategy across the crossdock network; readiness for 50+ FC launches; a Kaizen / Lean trainer; teams built from scratch — public-profile inference in "Read me first") says she will test whether the mechanisms transfer to her world. Open with S11 (a boarding process behind published gates, run from a weekly input/output review) and hold S12 (a committed roadmap re-sequenced on cost-to-serve evidence). v2 adds five distinct Flexport primaries — S11-A the Monday review as an analysis, S11-B launch readiness as standard work, S11-C retiring an acquired product's book, S12-A the Asia latency investigation, S16-A the data model under the review — so every Leadership Principle has a primary and a backup from one company. Lead every answer with the mechanism left behind, the priced trade-off, and the team that grew to own it. Systems are enablers; the process redesign and its business results are the story.

LP focus — my guess, not confirmed: Deliver Results · Hire & Develop / Earth's Best Employer · Dive Deep. Amazon does not disclose the assignment; the guesses are reasoned from the interviewer's title, the JD and her public profile in "Read me first" (public-profile inference, labeled as such) and should be held loosely — Think Big / Frugality and Ownership / Earn Trust remain live alternates carried by the twist maps.

Also expect: "tell me about yourself" (75-second version, once, here) and "why Amazon" (hiring managers usually ask it); one functional question on how I would approach the NACF process space.

Canon: amazon/amazon-l6-scm-master-packet.html (§1.2 roster, §4.1 ledger). Every number below is that packet's value; every dollar carries its basis label (record · user anchor · modeled · priced).

Question bank — 28 likely questions with answer plans 101

Backup bench — S9, S19, S13 104

NUMBERS I MUST NOT GET WRONG — canon values, basis labels, never-say 113

WHAT TO SAY ABOUT MY ROLE — the I-versus-we line for each story 116

VERIFY BEFORE YOU SAY IT — the few specifics in no source, each with its safe sentence 117

SOURCE TRACE — every number: source file · page / row / sheet · match status 118

Every new story is tagged NEW and carries five labeled facets (data analysis · solution design · math & data logic · implementation · probe questions), four `Before / Fix / After / Dollars` tables, a four-question behavioral pack, three angle cards and three trap drills. Each primary opens with a SAFE-SAY box (the sentence for its most attackable number and for "what is your source for that?"). Yellow VERIFY-WITH-RAJESH tags mark only the specifics that are in none of the source files; each is repeated on the VERIFY page with the safe sentence to say instead.

5-Minute Cram Sheet — Snigdha Tripathy · Wed Oct 29 · 10:00 am PDT NEW

HER HOOKS → MY PROOF (PUBLIC-PROFILE INFERENCE)

- **EU IXD placement strategy** → S11 wave machine: a selection bar published before the first node, a ~50-container calibration per node, a public hold when a node misses; S11-C: three brokers = 75.0% of containers, so the few lanes that carry the volume get bespoke handling.
- **$80MM savings** (her number — framing only) → my discipline on dollars: ~$5M avoidance said once (S12); $0.66 → $0.03; anything priced is "priced, not saved" (S16-A).
- **50+ FC launches** → S11-B readiness: four gates, 100 containers × 7 checks, six graduation criteria, and the pilot that ran later than the first testing plan, owned.
- **Kaizen / Lean trainer** → S11-A waste = 3.67 touches and standard work; S11-B jidoka (stop the line, hold wave 3); S12-A genchi genbutsu and PDCA; S16-A poka-yoke (bridge table, parity gate).

THREE OPENING SENTENCES

- *Most significant delivery.* "Cost-to-serve on Flexport's shipment-visibility product went from sixty-six cents a container to three while customers went from seven to sixty-eight — nine point seven times — with zero rollbacks, because boarding went through six published gates, not around them."
- *Changed a committed plan.* "I re-opened my manager's eighteen-month roadmap privately, with numbers — partners first, operators on the same chassis — and value landed in month six with sixty-six percent less effort."
- *Dive into data.* "A twenty-two-fold cost drop decomposes into two levers — containers needing a human, and touches on each — and which one moved decides what you do next."

FIVE NUMBERS I MUST NOT GET WRONG

- **7 → 68 = 9.7×** — never rounded up; no other growth multiple is ever said.
- **$0.66 → $0.03, about 95%**; direct dollars ≈ $50K a year *modeled*; the ~$1.5M pre-production estimate is a user anchor, separate, never added.
- **~$5M** is avoidance, said once — never annual; run-rate ≈ $1.5M a year is a separate modeled number.
- **S11-C:** printed $185,892 = six of nine segments; nine rows = $254,952; lead with containers (294,581).
- **S12-A:** never quote 81%; like-for-like is −44.2% overall (Apr → Sep). **S16-A:** $103,680 and $100,360 are prices, not savings.

SEVEN STORIES — TELLING ORDER AND THE ONE NUMBER

1	**S11**	**7 → 68 customers (9.7×); $0.66 → $0.03**	Deliver Results · Ownership
2	**S11-B**	**100 containers × 7 checks; 41 of 59 failures at two hops**	Highest Standards · Customer Obsession
3	**S12**	**month 18 → 6; −66% effort; ~$5M avoidance (record), said once**	Think Big · Backbone · Frugality
4	**S11-A**	**22× = 6.0× (coverage) × 3.67× (touches)**	Dive Deep · Earn Trust
5	**S12-A**	**Asia 21.19 s vs US 3.3 s = 6.42× on 45.3% of views**	Dive Deep · Customer · Bias for Action
6	**S11-C**	**79 of 79 customers placed; 3 brokers = 75.0% of containers**	Customer Obsession · Broad Responsibility
7	**S16-A**	**system accuracy 60% → 90%; over $100K priced, not saved**	Invent & Simplify · Frugality

BRIDGE IN ONE BREATH (BOOKLET FRAMEWORKS)

- Inbound capacity: dock doors × hours × unload rate; utilization knee ≈ 85%; labor by UPH; cubic fill.
- Inventory health: weeks of cover — under 2 expedite, 2–4 healthy, over 6 excess; safety stock z · σ · √LT.
- Placement: distance-to-customer priced against cost per unit moved — the edge-near-demand logic of S12-A, the concentration logic of S11-C.

ROOM RULES

- Pitch, land the metric, **stop**. Name who owned what — program-lead voice.
- Every dollar with its basis word; if a number is yellow in the text, check the last page first.
- Overlaps: S16-A, S11-C, S12-A, S11-B facts are also in other packets — see "Read me first"; fall back to the router's backup if the panel flags a clash.
- Bridge in one sentence, then hand it back to her with a question.
- If challenged on a number, read the story's SAFE-SAY box; if it is yellow, read its safe sentence on the VERIFY page — never the unconfirmed specific.

Question → Story Router — 16 Leadership Principles + 11 common prompts NEW

Each Leadership Principle row quotes a **real question from the Amazon question bank (AIQB reference guide)**, then routes it: find the LP, tell the primary (the B-card is the 90-second STAR in that story's Behavioral Pack), keep the backup for "another example". One number, then stop. Never the same story twice in one loop.

LEADERSHIP PRINCIPLE · AIQB QUESTION	PRIMARY STORY · CARD	BACKUP	15-SECOND OPENER	ONE NUMBER
Customer Obsession *"Tell me about a time when you had to balance the needs of the customer with the needs of the business. What did you do? What was the result?"* AIQB: Customer Obsession Q8	S11-C · B1 — nine segments, 79 destinations	S11-B · B2 (shadow accounts) · S11 · B3	"Every one of seventy-nine customers got a destination and a date — not an end-of-life email."	**79 of 79 = 55 + 3 + 9 + 9 + 3**
Ownership *"Give me an example of an initiative you undertook because you saw that it could benefit the whole company or your customers, but wasn't within any group's individual responsibility so nothing was being done."* AIQB: Ownership Q3	S11-A · failure card — the review nobody owned, run by hand for months	S11 · B2 (the critique accepted)	"Nobody owned the measurement system, so I ran it by hand every Monday — about four hours a week at its worst — until the formulas were stable enough to automate."	**40.0% → 21.9% week, explained**
Invent and Simplify *"Give me an example of a complex problem you solved with a simple solution. What made the problem complex? How do you know your solution addressed the problem?"* AIQB: Invent and Simplify Q1	S16-A · B1 — four systems, one pipeline	S11-A · conflict card (seven metrics)	"Four systems and one person made the Monday number; I simplified it to one pipeline and seven frozen definitions."	**system accuracy 60% → 90%**
Are Right, A Lot *"Tell me about a time when you didn't have enough data to make the right decision. What did you do? What path did you take? Did the decision turn out to be the correct one?"* AIQB: Are Right, A Lot Q1	S11-A · B3 — 99.4% on three touches	S11-A · B4 (the carrier-format-change week) · S12 · failure card (Asia 21.19 s the plan did not see)	"One week printed ninety-nine point four percent — on three touches. I did not have enough data to steer on it, so I printed it as a data miss."	**N = 3 → discarded**
Learn and Be Curious *"We all have things about ourselves we'd like to improve on at work. Give me an example of something that you've worked on to improve your overall work effectiveness."* AIQB: Learn and Be Curious Q4	S11-B · B4 — the honest miss	S12-A · failure card (no regional P50 / P90)	"The pilot ran later than the first testing plan; my test estimates were optimistic and monitoring arrived late, so I size testing on hop count now."	**41 of 59 failing rows at two hops (my recount)**
Hire and Develop the Best *"Describe a time when you constructed a team to accomplish a goal. What factors did you consider in constructing the team? Did you factor diversity into your team construction?"* AIQB: Hire and Develop the Best Q9	S11 · the input owners across nine teams who sign their metric — a team-level answer; for a named person see VERIFY-WITH-RAJESH · V1	S11-A · conflict card (owners sign what they are red against)	"I grew the input owners across nine teams into people who sign and defend their own definitions; the review runs on them, not on me."	**9 teams · 7 definitions**
Insist on the Highest Standards *"Tell me about a time when you had to make a decision between standards and delivery. What tradeoffs did you have make? What was the outcome?"* AIQB: Highest Standards Q4	S11-B · B1 — UAT opens at 80%	S16-A · B4 (1% parity gate) · S11-A · B2	"UAT did not start until eighty percent of shipments showed minor-to-no issues — the gate was data quality, not the calendar."	**100 × 7 checks · 80% gate**

LEADERSHIP PRINCIPLE · AIQB QUESTION	PRIMARY STORY · CARD	BACKUP	15-SECOND OPENER	ONE NUMBER
Think Big *"Give me an example of how you have changed the direction or view of a specific function/department and helped them embrace a new way of thinking. Why was a change needed?"* AIQB: Think Big Q2	S12 · B1 — month 6 not 18	S11 · B1 (7 → 68 on the same ops team)	"The roadmap said eighteen months to first value; I re-opened it and landed value in month six, with sixty-six percent less effort."	**18 → 6 months; −66%**
Bias for Action *"Give me an example of a calculated risk that you have taken where speed was critical. What was the situation and how did you handle it?"* AIQB: Bias for Action Q1	S12-A · B3 — reversible changes first	S12 · reversal trigger written before the swing	"We started with changes that could be undone — a double CDN removed, a firewall on — and held the expensive one for the metrics."	**52-day plan; 4 of 8 rows done**
Frugality *"Give me an example of how you have helped save costs or eliminate waste within your role or organization. What was the situation? What was the impact?"* AIQB: Frugality Q1	S12 · B3 — ~$5M avoided	S16-A · B3 (priced, not saved)	"About five million dollars of cost avoidance — engineering never spent plus value pulled forward — and I say it once."	**~$5M avoidance (record), said once**
Earn Trust *"Give me an example of a tough or critical piece of feedback you received. What was it and what did you do about it?"* AIQB: Earn Trust Q2	S11 · B2 — the critique accepted	S11-A · B3 · S12 · B4 · S11-C · B4	"Leadership said the program wasn't showing value; I'd been reporting activity, not evidence — and I accepted that first."	**#3 → #14 of 16 → rollout unlocked**
Dive Deep *"Tell me about a problem you had to solve that required in-depth thought and analysis. How did you know you were focusing on the right things? What was the outcome?"* AIQB: Dive Deep Q3	S11-A · B1 — 22× = 6.0× × 3.67×	S12-A · B1 · S16-A · B2 · S11-B · B3	"A twenty-two-fold cost drop — and I can say which lever did it: six times fewer containers needing a human, times 3.7 fewer touches."	**22× = 6.0× × 3.67×**
Have Backbone; Disagree and Commit *"Tell me about a time when you strongly disagreed with your manager or peer on something you considered very important to the business. What was it and how did you handle it?"* AIQB: Have a Backbone Q1	S12 · B2 — private first, two days to break it	S11-C · B3 (the dissent on the page)	"The plan had my manager's name on it; I read it to him alone, with numbers, and gave engineering two days to break it."	**2 points argued, 1 adjusted**
Deliver Results *"Tell me about a time when you not only met a goal but considerably exceeded expectations. How were you able to do it? What challenges did you have to overcome?"* AIQB: Deliver Results Q3	S11 · B1 — both targets early	S12 (value in month 6)	"Both public targets — 68 customers and 170 monthly users — landed two months early with zero rollbacks, behind six published gates, not around them."	**7 → 68 (9.7×)**
Strive to be Earth's Best Employer *"Describe a time when you implemented a change at work aimed at improving the work experience of yourself or coworkers. What was the goal?"* AIQB: Strive to Be Earth's Best Employer Q3	S16-A · B1 — retired the Monday stitching: one engineer maintains the pipeline instead of one PM rebuilding it	S12 · B4 (operators' two quarters, priced and published)	"Every Monday I stitched four systems by hand and the hours came out of rollout time; I turned it into a pipeline so the review no longer depends on one person."	**system accuracy 60% → 90%**

LEADERSHIP PRINCIPLE · AIQB QUESTION	PRIMARY STORY · CARD	BACKUP	15-SECOND OPENER	ONE NUMBER
Success and Scale Bring Broad Responsibility *"Tell me about a time when you considered everyone who was affected by your work, not just your direct customers or people within your organization."* AIQB: Broad Responsibility Q5	S11-C · B2 — concentration	S12-A · B2 (Asia = 45.3% of views)	"Three customers were four percent of the book and three-quarters of the containers — a template would have been wrong for them."	**3.8% of customers = 75.0% of containers**

ELEVEN COMMON NON-LP PROMPTS

PROMPT	PRIMARY	BACKUP	NUMBER

Decided with incomplete data	S12-A (P95 on 316 tail views)	S11-A (N = 3)	**P99 = 63 views vs P95 = 316**
Missed a deadline	S11-B · B4	S16-A (the two-week security-review miss — one sentence only)	**later than the first testing plan**
Mentored someone	S11 — owner growth (team-level) VERIFY-WITH-RAJESH · V1	S11-A	**owners across 9 teams signing definitions**
Delivered under a tight timeline	S12-A · B3	S11 · B1 (both targets two months early)	**52-day plan**
Changed your mind because of data	S12 (adjusted 1 of 2 points)	S11-B (re-sized testing on hop count)	**1 of 2 points**

SAME STORY ASKED TWICE — SWITCH TO A DIFFERENT ANGLE CARD (LP · HEADLINE METRIC)

STORY	DATA / ANALYTICAL CARD	CONFLICT / BACKBONE CARD	HONEST-FAILURE CARD
S11	**Dive Deep** — $0.66 / $0.18 = 3.67 → 0.17 touches	**Have Backbone; Disagree and Commit** — six criteria; wave 3 held	**Learn and Be Curious** — #3 → #14 of 16
S11-A	**Dive Deep** — 22.0× = 6.0× coverage × 3.67× touch efficiency; fair split 56% / 44% (modeled)	**Insist on the Highest Standards** — seven frozen metrics, each signed by the owner who would be red against it	**Ownership** — by hand for months, about four hours a week at its worst; no longer a single point of failure once the pipeline matched within 1%
S11-B	**Dive Deep** — 41 of 59 (69.5%) at route + milestone; 3 of 105 all-seven-clean	**Ownership** — nine teams aligned on one seam; time to localize cut about 50% (secondary source)	**Learn and Be Curious** — first plan early November → launched December 2021; hours to localize a bug at six-plus layers
S11-C	**Dive Deep** — 3.8% of customers = 75.0% of containers = 54.7% of ARR	**Have Backbone; Disagree and Commit** — four dissenting inputs; one decider; each impacted party commits	**Learn and Be Curious** — 2 open questions; break-even $15,491 / month
S12	**Dive Deep** — 339.5 min × $0.45 ≈ $153; −25% vs −50%	**Have Backbone; Disagree and Commit** — two points argued; one adjusted	**Are Right, A Lot** — 21.19 s vs 3.3 s
S12-A	**Dive Deep** — 6.42× on 6.31k of 13.92k views	**Have Backbone; Disagree and Commit** — one conditional row (Q3 or later); 4 of 8 rows done	**Learn and Be Curious** — window-mismatched 81.1% — not quoted
S16-A	**Dive Deep** — 12 / 18 = 0.667 vs 12 / 10 = 1.20 (illustrative); 4% drop (record)	**Have Backbone; Disagree and Commit** — seven frozen metrics; one bridge table	**Earn Trust** — two-week security-review miss; zero Monday reviews skipped

B-cards: each story's Behavioral Pack has four separate 90-second STARs (B1–B4), each headed by the real AIQB question it answers; the three angle cards (data · conflict · honest failure) give a different opener and metric when the same story is asked twice.

Read me first

The interviewer's lens (inference from title, JD and public profile — the profile parts labeled)

Inference from the title. The hiring manager owns the team this role joins and the outcomes it is measured on. A Senior Manager of Supply Chain in NACF is accountable for network-level processes — how inventory is planned, placed, moved and recovered across fulfillment centers — and for the operating cadence (weekly business reviews, goals, mechanisms) that keeps those processes honest. She is the one interviewer who will also judge *fit for the actual work*: can this person define and run a process across teams that do not report to them, make value legible to leadership, and change a committed plan on evidence without breaking trust.

What that means for the answers. Lead with scale-with-mechanisms (S11) and roadmap judgment under unit economics (S12); v2 adds five distinct Flexport primaries (S11-A, S11-B, S11-C, S12-A, S16-A) so every Leadership Principle has a primary and a backup from one company — see the Router. All seven are Flexport stories, told as process redesigns: a boarding process behind published gates with a weekly input/output review, a launch roadmap re-sequenced on cost-to-serve, and the analysis, readiness, retirement, latency and data-model work underneath them. She will probably also ask the openers — "tell me about yourself" and "why Amazon" — and a functional question on how I would approach the NACF process space in the first 90 days. The JD's own phrase, "designing or modeling the supply chain as opposed to working in it," is the lens to speak to: I designed the boarding process and the review; I did not run the ops desk.

What her public profile adds (public-profile inference, labeled)

The profile, as pasted (public-profile inference — directional, not verified biography). 11+ years at Amazon across operations, launch and learning: EU IXD & Placement Operations Manager, Luxembourg, 2017–21 — defined the EU inventory-placement strategy for the crossdock network (distance-to-customer, speed-vs-cost) and built the team ground-up (+$50MM savings in 2020); Senior Manager EU IXD, 2021–22 — ran the EU crossdock network with a team of six plus interns ($80MM savings in 2021; IXD grown to 60% of inbound, +46% YoY); Senior Launch Program Manager, 2014–17 — readiness for 50+ FC launches including Amazon.in; FC Learning & Development Manager — Kaizen / Lean / CI training, learning curves and skill matrices, delivered an S-Team goal; Dell training background; SP Jain PGPM. **These are her numbers from her profile, quoted for framing only — they are not canon and never enter my stories.**

What that means for the answers. Three adjustments. First, lead with the *mechanism left behind* and who owns it now — she built teams and mechanisms herself (a placement strategy, a crossdock network, an L&D program), so "what still runs without you?" is her native question. Second, *price the trade-off* the way she priced distance-to-customer against speed and cost — S11's boarding pace vs automation maturity and S12's operators' two further quarters are exactly her shape of decision. Third, expect *transferability probes* — "how would this apply to a placement / network problem?" — and expect her to spot borrowed Leadership-Principle language: answer in the story's own words (gates, denominators, reversal triggers), never in recited LP slogans.

Three guessed LP focus areas, with rationale

> **Labeled guess.** Amazon assigns 2–3 Leadership Principles per interviewer and does not disclose them. These three are inferred from the title, the JD and the public profile above (public-profile inference); if the first question lands on a different LP — Think Big / Frugality for S12, Ownership / Earn Trust for the critique-and-private-first threads — the twist maps under each story carry the pivot.

GUESSED LP	WHY THIS INTERVIEWER WOULD CARRY IT	STORY TO OPEN · BACKUP
Deliver Results	The HM carries the outcome LP almost by default — she needs evidence the candidate lands public targets with the organization intact. S11's two public targets two months early with zero rollbacks is the cleanest record in the set.	S11 (open) · backup: S18 in the master packet — only if S11 is already spent
Hire & Develop / Earth's Best Employer (one of the two)	Her profile is teams built and grown: a placement team built ground-up in Luxembourg, a team of six plus interns running the EU crossdock network, and an S-Team goal delivered as an FC L&D manager on Kaizen / Lean / CI training and skill matrices (public-profile inference). She will probe who grew on my programs: S11's input owners across nine teams signing the definitions they would be red against, wave teams grown into owners; S12's delivery teams now running the burn-up, the swap rule and the re-estimation habit.	S11 (owners own their lines) · S12 (mechanisms the teams now run)
Dive Deep	She ran a crossdock network hands-on and defined placement strategy at node level (public-profile inference) — expect her to test whether my numbers survive decomposition: CTS $0.66 → $0.03 cross-walked to ≈3.7 touches at $0.18 each; S12's cost translated at the work-item grain (339.5 minutes; 2,200 interactions per departed shipment). The Ownership / Earn Trust probes she may still carry are covered in the twist maps — the critique accepted (S11) and the private-first flip (S12).	S11 (per-container cross-walk) · S12 (work-item grain)

Answer strategy — business first, systems as enablers

- **Open with the process problem and its cost, not the system.** First sentence names the broken process (Plan, Source, Make, Deliver or Return), who it hurt (customer, Finance, the floor) and the baseline number. The platform appears only as the enabler of the redesign, in one clause.
- **Use the JD's four outcome words as the results frame:** reliability (did the promise hold?), responsiveness (how much earlier did we see it?), cost efficiency ($ with its basis label), asset utilization (capital, labor-hours, capacity released).
- **Action = operating-model redesign in gated phases** — Discovery → Plan & Design → Build & Test → Cutover → Hypercare, each spoken as entry bar · what I delivered · exit bar. Say the gate that fired, not the meeting that happened.
- **Every dollar carries its basis word in the same breath** — record · user anchor · modeled · priced. A record dollar is said flat; a modeled dollar is said with its inputs. Never promote a modeled number to record.
- **Program-lead voice.** I owned definitions, rules, gates and the signature chain; engineers, SIs and vendor teams configured and built to the spec I signed. The only platform personally configured in canon is Manhattan DOM.
- **The pitch ends on the primary metric.** Then stop. Silence after the pitch is the interviewer filling their STAR worksheet; their probes are the second half of the answer.
- **For the HM specifically:** name the mechanism in Amazon's own vocabulary where it is honest — a weekly input/output review with frozen metric definitions, graduation criteria published before the wave, a reversal trigger written before the flip. Do not claim to have invented the WBR; say it was copied from a trusted review, which is the point.

- **Answer her native question — what did you leave behind, and who owns it now?** Every story lands on a mechanism that still runs without me (the Monday review and the graduation gates; the rebuild-vs-reuse rule and the scope tripwire) with a named owner. She built teams and mechanisms ground-up (public-profile inference); that is the evidence she pattern-matches.
- **Price the trade-off in her units.** She priced distance-to-customer against speed and cost for a crossdock network (public-profile inference); my versions are boarding pace vs automation maturity (S11) and partners-first vs operators' two further quarters, priced and published (S12). Say the trade and its price, not just the win.
- **Two warnings (public-profile inferences).** She tests transferability — "how would this apply to a placement / network problem?" — so practice the bridges in the twist maps before the call. And she spots borrowed LP language: never recite slogans ("I was customer-obsessed"); say the gate, the denominator, the reversal trigger in the story's own words.
- **Have the openers ready** — the 75-second "tell me about yourself" and the 60-second "why Amazon" from the master packet (newest to oldest; Sephora → Flexport → Elementum → Manhattan). Say the long version once, here.

Loop-consistency rule. One question, one story; never the same story to two interviewers — interviewers compare notes. Held for other packets (do not spend here): S1/S3 (Lan) · S2/S18 (Goforth) · S6/S8 (Hoerger) · S15/S14 (Josyula). **v2 overlap flags — confirm before the loop.** This packet deliberately tells five Flexport records that another packet also touches: **S16-A** (Snowflake data model; Josyula's primary is S16, told as Ownership and the security-review miss — here lead with grain, join and reconciliation; the S16-A failure card is that same two-week miss, so if the panel notes show Josyula tells it, give it one sentence and pivot to the data model); **S11-C** (the Crux customer transition — the loop packet's S10, "79 customers, a destination and a date each"; no other panel carries it as a primary, but Goforth's pilot bench touches the Crux shadow accounts); **S12-A** (Asia latency; Hoerger's doc bench); **S11-B** (pilot rollout schedule and testing approach; Goforth's doc bench); the audit-logs PRD and the schedules solution are Lan's bench and are not used here. If the panel notes show a clash, drop the flagged story to a one-line pointer and use its router backup. If pushed for "another example" on an LP, use the named backup in the router, the question bank or the backup bench, never a story allocated to another interviewer.

How to read the "L6 level evidence" block under each story. Amazon's L6 functional bar (user-supplied rubric): *Ambiguity* — strategy or network undefined; I select the stakeholders, set the goals, deliver independently. *Scope & influence* — team-level scope; influences one to two levels up. *Execution* — tactical and strategic; simplifies or extends; applies best practices; force-multiplies; mitigates long-term risk; makes the short-versus-long-term trade-off explicit. *Impact* — long-term team goals. *Process improvement* — operational-excellence best practices institutionalized. *Complex* — visible risks, roadblocks and constraints mitigated through expertise, judgment and influence to consensus. Overview themes the block is tuned to: designing and modeling the supply chain rather than working in it; developing new processes for others to own; root-cause mechanisms that resolve trending issues at scale; recommendations to leadership that outline competing metrics. The block sits right after Results so the evidence is on the page when the probing starts.

The stories — business-first, canon numbers

Seven Flexport primaries: two flagships (S11, S12 — deepened, with the original pages kept) and five new (S11-A, S11-B, S11-C, S12-A, S16-A). Each: 60-second pitch → SAFE-SAY box → Situation/Task → Action in gated phases → Results → L6 evidence → five labeled facets (data analysis · solution design · math & data logic · implementation · probe questions) → four-table math → sensitivity → statements → 20-second version and NACF bridge → behavioral pack → three angles → three trap drills.

S11 — Flexport — Shipment Visibility launch: a boarding process behind published graduation gates, run from a weekly input/output review (cost-to-serve $0.66 → $0.03 across 7 → 68 customers) DEEPENED

LPs this story can serve here: Deliver Results (primary) · Ownership (accepted the critique, owned the measurement) · Customer Obsession (graduation criteria per wave, CSAT in the gate) · Earn Trust (the discarded 99.4% week) · Hire & Develop (backup — wave teams grown into owners)

Process family: Deliver — customer onboarding / service-delivery process; weekly operating cadence; launch readiness and staged rollout

SAFE-SAY — TWO SENTENCES TO SAY EXACTLY

Most attackable number. “Seven to sixty-eight customers — nine point seven times — and a hundred and seventy monthly users, both landed two months early; thirty-two thousand shipments was the target I managed toward, not a result I claim.”

“What's your source for that?” “The targets and the roll-out record are in the program's own documents and my interview workbook; nine point seven is my division, sixty-eight over seven, and the cost-to-serve arc of about sixty-six cents to about three cents is the same record, rounded to about ninety-five percent.”

LEADERSHIP PRINCIPLES THIS STORY CARRIES — ONE-LINE PROOF SENTENCE EACH

Deliver Results Both public targets — 68 customers and 170 monthly active users — landed two months early with zero rollbacks (the 32,000-shipment figure was a target I managed toward, not a result), because boarding went through six published graduation criteria rather than around them.

Ownership I accepted the critique (#3 to #14 of 16) as being about evidence, not effort, and owned the measurement system myself — by hand every Monday for months — before it was handed to a pipeline.

Customer Obsession CSAT at or above the consignee average was inside the gate, every client entered on a ~50-container calibration of its own freight, and 100 real containers ran seven checks before the first paying customer.

Earn Trust A flattering 99.4% week resting on three touches was printed as a data miss, and wave 3 was held in public on an ETA-accuracy miss — trust came from numbers that survived the next Monday.

Honesty label. Program owner across nine teams / ~100 people; the WBR format was copied from an existing leadership review (the LSA review), not invented; build-week counts are illustrative; the ~$1.5M pre-production measurement saving is a separate user-anchor figure (my own estimate, not a program-document number), never merged with cost-to-serve. Nine teams built and operated; I owned the boarding process, the measurement system and the pre-prod proof.

WHAT IS SHIPMENT VISIBILITY? — THE ONE-MINUTE EXPLAINER (FROM THE PROGRAM DOCUMENTS; RECORD-FROM-DOCS)

The minute. Shipment Visibility — "SV" — is Flexport's client-facing visibility product in the Client App: one pane where a client watches container milestones across their whole book, Flexport-carried and non-Flexport-carried shipments alike, so track-and-trace stops being emails to an ops desk and becomes a product the client logs into. It also created a "visibility-only" client segment — companies that bought visibility first were a deliberate upsell path into

Flexport freight. The 2021 plan priced the problem it solved: roughly $3.92M a year of manual track-and-trace salary across the ops org against about $263K of vendor spend, with only 18 of 99 milestones automated at the time. RECORD-FROM-DOCS

The machinery behind the story. Product standards: coverage 90%+, accuracy 95%, timeliness 90%, a fail-safe switch, dashboards and alarms — under the operating rule "edits are the enemy": every human correction is an automation defect, not a fix. Rollout: a free pilot in graduated waves — wave 1 two named clients (the first two hand-carried customers) around Q4 2021, wave 2 four of a seven-client pool around Q1 2022, wave 3 twenty-plus around Q2 2022, full roll-out H2 2022 — each client entering on a ~50-container calibration and graduating on six published criteria. Testing: four gates before launch — a 100-container live test, biweekly bug bashes on the client job stories, shadow accounts fed real Crux data, and UAT gated on data quality (80% of shipments minor-to-no issues). And Crux — the acquired visibility product — was transitioned onto SV by end 2022: 79 customers, $185,892 printed ARR (six of nine segments — S11-C re-foots it), 294,581 containers. RECORD-FROM-DOCS

Doc-vs-canon footnotes: the pilot schedule phrases the SLA criterion as "90% of verifications within 24–48h"; canon says "reviewed within 24h" — canon wins, say 24h. The 95% accuracy standard is the 2021 plan's bar for milestone data, not this story's ETA-accuracy metric (60% → 90%, canon) — never mix them. The $3.92M / $263K figures are the plan's ops-org business case, a different basis from canon's per-container CTS — never merged. Wave timing and the six criteria match the master packet.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. Flexport's shipment-visibility product had public commitments — 68 monthly active customers, 170 MAU, 32K shipments — and was serving seven pilots at a cost-to-serve of $0.66 a container, most of it human touches. Sales wanted the entire pool boarded at once; leadership said the program was not demonstrating value and it was about to drop from #3 to #14 of 16 initiatives. The process problem was that boarding ran faster than the automation could carry, and nobody could see it. **Task.** As program owner across nine teams, I owned the boarding path, the measurement system and the pre-production proof. **Action.** I rebuilt boarding as a gated process: six graduation criteria published to Sales before wave one, a launch gate of 100 real containers across seven checks, and a weekly input/output review — seven frozen metric definitions, each signed by the owner who would be red against it, every input tagged to the output it moves — copied from a review leadership already trusted and run by hand every Monday for months. Waves boarded only through the criteria; wave three was held in public on an ETA-accuracy miss and became the cleanest wave. When a flattering 99.4% week turned out to rest on three touches, I printed a data miss instead. **Result.** Primary metric: cost-to-serve per container $0.66 → $0.03, about 95%, across customers 7 → 68 — 9.7× — with zero rollbacks and no added ops headcount; automation 40% → 90%, accuracy 60% → 90%, both public targets two months early. The ~$1.5M pre-production measurement saving is a separate user-anchor figure — my own estimate — and I keep it separate.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — Senior leadership told me the visibility program was not demonstrating value at the anticipated rate — it would drop from #3 to #14 of 16 initiatives. I had been reporting activity, not evidence. The critique was about evidence, not effort, and I accepted that first.

The business process underneath: customer boarding (Deliver) ran as a sales push — board the whole pool now — against an operation where most containers were still touched by hand. Cost-to-serve was $0.66 a container (≈3.7 human interactions at the record cross-walk of $0.18 per interaction); automation covered 40% of containers; ETA accuracy was 60%. The public commitments were 68 monthly active customers, 170 MAU and 32K shipments, off seven pilots.

The cost of leaving it: a bad first impression at scale with rollbacks, ops headcount growing with the customer count, and the program losing its funding slot because value was invisible.

T — Program owner across nine teams / ~100 people: own the boarding path, the measurement system and the pre-production proof — and make value legible to the leadership that decides rollout pace and funding, with zero

rollbacks and no added ops headcount.

Baselines on the table: customers 7 (target 68) · cost-to-serve $0.66/container · automation 40% · ETA accuracy 60% · public targets 68 customers / 170 MAU / 32K shipments · no instrument leadership trusted.

KEY CHALLENGES — WHAT THE PROGRAM RECORD ADDS (FROM THE PROGRAM DOCUMENTS; RECORD-FROM-DOCS)

- **Rollout sequencing under a free pilot.** Pilot clients pay nothing, so every wave spent engineering, data and ops capacity before revenue; the pool had to be sequenced 2 → 4-of-7 → 20+ against a ~50-container calibration per client and six graduation criteria, with GO/NO-GO decisions taken monthly. That is the doc-level version of "board no faster than the automation can carry." RECORD-FROM-DOCS
- **Testing gates before any launch.** Four gates stood between build and client: a 100-container live test watched end-to-end, biweekly bug bashes on the client job stories, shadow accounts (real Crux data in dedicated demo accounts), and UAT that did not start until 80% of shipments showed minor-to-no issues. The gates are why "zero rollbacks" was achievable. RECORD-FROM-DOCS
- **An acquired product's customers in the middle of the rollout.** Crux's 79 customers — $185,892 printed ARR (six of nine segments — see S11-C), 294,581 containers — had to be transitioned onto SV by end 2022, including cancel-vs-transition decisions by segment and per-customer calls for the largest accounts, while the pilot waves were still boarding. Migration risk ran in parallel with launch risk. RECORD-FROM-DOCS
- **Data quality as a product standard, not an ops task.** The 2021 plan set coverage 90%+ / accuracy 95% / timeliness 90% with a fail-safe switch, and named the enemy: human edits. "Edits are the enemy" is the sentence behind the story's automation 40% → 90%. RECORD-FROM-DOCS

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery** — wrote the honest diagnosis (activity, not evidence); inventoried what leadership actually decides on (rollout pace, funding); chose to copy the LSA review's format rather than invent one. *Exit bar:* leadership agrees the questions the review must answer weekly; ~50-container calibration entry bar per client.
- **Plan & Design** — froze seven metric definitions (coverage auto, coverage with human, tickets, tickets per active container, 4PL SLA %, 3PL SLA %, delta); input→output tagging; the ±5% week-over-week red/green rule; the 15-day active rule as the honest denominator; six graduation criteria published to Sales before wave 1 — DQ ≥ 90%, ETA ≥ 80%, SLA 90% reviewed within 24h, ≥100 containers + 5 features, stability, CSAT ≥ consignee average; launch gate 100 real containers × 7 checks; pre-prod sample size 300 containers for ±1.6% at 95% confidence. *Exit bar:* each input owner signs the definition they will be red against; first Monday deck dry-run.
- **Build & Test** — ran the review by hand every Monday (1.5–2 hrs, later ~4); pre-decomposed every red with an owner and a dated fix; enforced the data-honesty rule — a truncated week is a data miss, not a result; pre-prod ingest with per-hop monitors and kill switches; load proof 500 containers / 20 min / 99.6%. *Exit bar:* two consecutive Mondays where every red arrives with an owner and the number verifies the following week.
- **Cutover & Go-Live (waves)** — W1 (2 clients) → W2 (4 of a 7-pool) → W3 (20+) held in public on an ETA-accuracy miss traced to one bad source → full rollout. The Monday review became the forum where the rollout decision was taken. *Exit bar:* the VP unlocks the 68-client rollout two months early off the review's own numbers.
- **Hypercare / Close** — discarded a flattering 99.4% three-touch week and printed a data miss; handed the manual pull to a pipeline with the definitions in code (S16-A in this packet tells the data model; the full S16 telling belongs to Josyula's packet); left the critic steering by the numbers. *Exit bar:* automation 40 → 90%; CTS $0.66 → $0.03; same ops team at 68 customers.

Influence and ownership. Mine: the diagnosis, the frozen definitions, the review built by hand weekly, the graduation criteria, the hold decisions and the pre-prod measurement design. Nine teams built and operated; each input owner signed the definition they would be red against; the VP took the rollout decisions in the review. The Sales push to board everything now was answered with gates published before wave 1 — so when wave 3 was held, it was the rule firing, not a judgment call; the held customers became the cleanest wave.

> **Designed the process; others own it now.** I designed the review, the definitions and the graduation gates; the input owners across the nine teams run their lines and the pipeline (S16-A) carries the definitions in code — the review steers without me. **Trade-off put to leadership.** My recommendation to leadership outlined the competing metrics explicitly — boarding pace and customer count vs automation coverage and ETA accuracy — and proposed to board no faster than the automation could carry; wave 3 was the trade made in public.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY (CANON NUMBERS ONLY)

- **$** — cost-to-serve per container $0.66 → $0.03 (record; about 95%); direct CTS dollars ≈$50K/yr *modeled* on an illustrative container count — the value is scale without headcount, not the direct dollars; the ~$1.5M pre-production measurement saving is a separate user-anchor figure, never merged with CTS.
- **#** — customers 7 → 68 (9.7×) with zero rollbacks and no added ops headcount; targets 68 customers / 170 MAU / 32K shipments (record).
- **%** — CTS about 95%; automation 40% → 90%; ETA accuracy 60% → 90% (record).
- **Time** — both public targets hit two months early; the rollout unlocked two months early off the review (record); pre-prod measurement path cut rollout proof from 6 months to 1.5.
- **Customer** — six graduation criteria published to Sales before wave 1 — including CSAT ≥ consignee average; wave 3 held in public on an ETA-accuracy miss and became the cleanest wave (record).
- **Quality** — a flattering truncated 99.4% week discarded and printed as a data miss; seven metric definitions frozen and later moved into code (record).

L6 LEVEL EVIDENCE — what the interviewer pattern-matches against the Amazon L6 functional rubric; every line is this story's canon, no new numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	Leadership said the program was not demonstrating value (#3 → #14 of 16) and no measurement system existed. I wrote the diagnosis (activity, not evidence), chose the nine teams' input owners as the stakeholders, and set the goals the review had to answer weekly.
Scope & influence	Nine teams built and operated; Sales held to criteria I published; the VP took the rollout decisions inside the review I ran — influence one to two levels up, from a program seat.
Execution trade-off + mechanism others now own	Boarding speed (Sales) vs automation maturity and ETA accuracy: wave 3 held in public on the miss. Mechanism others own now: the Monday input/output review and the six graduation criteria, with the seven definitions moved into code (S16-A).
Impact (long-term)	Customers 7 → 68 (9.7×) at CTS $0.66 → $0.03 with zero rollbacks and no added ops headcount; both public targets two months early; the review became the standing rollout forum.
Process improvement (standard work institutionalized)	Seven frozen metric definitions, input→output tagging, the ±5% week-over-week red/green rule, the 15-day active denominator, and the data-honesty rule (a truncated week is a data miss, not a result).
Complexity & consensus	A critical leadership and a Sales push to board everything now — answered by gates published before wave 1, each input owner signing the definition they would be red against; the VP unlocked the 68-client rollout off the review's own numbers.
Root cause at scale	The ETA-accuracy miss traced to one bad source and fixed there; the flattering 99.4% week traced to three touches and printed as a data miss — fixed at the definition and the source, not customer by customer.

PROBING — CHALLENGE Q&A TUNED TO THIS INTERVIEWER

> **HM — Why is this your Deliver Results story and not just a metrics story?**
>
> Because the results landed behind gates, not around them: both public targets two months early, 7 → 68 customers on the same ops team, zero rollbacks. The review and the graduation criteria are the mechanism; the about-95% cut and the 9.7× are the outcome.

HM — The direct dollars on a 95% cost reduction are small. Why lead with it?

Because it is honest and because the point was never the direct dollars: at the 32K-shipment target the direct saving is ≈$50K a year, modeled on an illustrative container count. What it bought is boarding 9.7× the customers without 9.7× the ops headcount — roughly two and a half people never hired (modeled — assumptions in the deepening's dollars table; not record headcount) — and a rollout unlocked two months early. The ~$1.5M pre-prod estimate is a separate user anchor and I never add it to this.

HM — Sales wanted everyone boarded. How did you hold the line without becoming the blocker?

By publishing the six criteria to Sales before wave one, so the rule did the refusing. Wave 3 was held in public on an ETA-accuracy miss traced to one bad source; the customers we held became the cleanest wave, and Sales had seen the gate before it fired.

HM — You discarded a 99.4% week. Walk me through that decision.

Three touches is not a week — a 95% confidence interval on N = 3 is wider than the metric. Printing it would have taught the VP a number that could not survive the next Monday. I printed a data miss. A review that flatters once is not trusted twice.

HM — What would you do differently, and how does this translate to my team?

Start the review at kickoff, not after the critique. At Amazon this is a WBR story told to the company that invented the WBR — the respectful version is that I copied a trusted format, froze definitions with their owners, tagged inputs to outputs and let the review make the rollout decision. Graduation criteria are launch gates published before the wave and held in public.

HM — What was yours and what was the team's?

Mine: the diagnosis, the seven definitions, the Monday build by hand for months, the criteria, the holds, the pre-prod measurement design. The nine teams built and operated; each input owner signed their own definition; the VP decided in the room. The format came from the LSA review — I did not invent it.

HM — Why waves at all? What did the calibration actually buy?

The pilot was free, so every boarded client cost engineering, data and ops before revenue — boarding the whole pool would have spent the program's credibility on clients we could not yet serve. The ~50-container calibration per client gave the data team a verified baseline on the client's own freight before scale, and the six published criteria converted "ready" from a feeling into a rule: wave 1 two clients, wave 2 four of a seven-client pool, wave 3 twenty-plus RECORD-FROM-DOCS. The canon version: waves boarded only through the published gates, and the held wave became the cleanest.

HM — How did you test before the first paying customer touched it?

Four gates, all from the program record RECORD-FROM-DOCS: a 100-container live test watched end-to-end; biweekly bug bashes on the client job stories; shadow client accounts — real Crux data fed into dedicated demo accounts so the clients' own data exposed the defects; and UAT that did not start until 80% of shipments showed minor-to-no issues. UAT was gated on data quality, not on the calendar — the testing version of the graduation rule.

HM — You were rolling out while an acquired product's customers sat on the old platform. How did you handle that risk?

As a parallel migration with its own decision rules, not an afterthought RECORD-FROM-DOCS: 79 Crux customers, $185,892 printed ARR (six of nine segments — see S11-C) and 294,581 containers, segmented — transition where SV fit, cancel honestly where it did not (two competitor SCM-SaaS accounts were canceled on published dates), per-customer calls for the largest accounts. Internal pushback on migration cost and feature parity was priced into the decision document, not overridden. The pilot gates kept quality honest while the migration ran beside it.

THE KEY MATH — COST-TO-SERVE, THE SCALE RESULT, AND WHY THE DOLLARS STAY SEPARATE

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Cost-to-serve before	`$0.66 / $0.18 ≈ 3.7 touches per container`	record; $0.18 per interaction is the record cross-walk	$0.66 — ≈3.7 touches
2	Cost-to-serve after	`($0.03 − $0.66) / $0.66 = −95.45%, say "about 95%"; $0.03 / $0.18 = 0.17 touches`	record	$0.03 — ≈0.17 touches
3	Scale	`68 / 7 = 9.7×; zero rollbacks; no added ops headcount`	record	9.7× (never "10×")
4	Direct CTS dollars	`32,000 shipments × 1.5–4 containers = 48–128K; × $0.63 = $30–81K`	modeled (containers per shipment illustrative)	≈$50K/yr modeled
5	Pre-prod measurement path	`n = 300 → ±1.6% at 95% CI; rollout proof 1.5 vs 6 months`	user anchor — separate canonical	~$1.5M, never merged with CTS
6	Week-over-week rule	`WoW = (B − A)/A = (21.9 − 40.0)/40.0 = −45% → red`	±5% red/green (record design; values are the 17 Jan and 31 Jan 2022 prints)	root cause: a carrier format change — measurement, not operators

Automation 40 → 90% and the WBR hours (1.5–2 → ~4 by hand) are this packet's canon; the loop packet carries different values (§1.3 conflict) — do not mix them in the room.

Where this lands at Amazon. This is the JD's "define, create, implement and execute processes" line in its purest form: a boarding process with published graduation criteria, a weekly input/output review with frozen definitions, and the discipline to hold a wave in public. Reliability (zero rollbacks), responsiveness (two months early), cost efficiency (about 95% CTS), asset utilization (the same ops team at 9.7× the customers).

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE WITH S11

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Tell me about a time you delivered results under pressure / against a target.	Deliver Results	Open on the critique (dropping #3 → #14) and the public targets; close on both targets two months early, 7 → 68, zero rollbacks. The gates are the how.	Skip the four-system data-pull detail unless asked for the data model — then S16-A carries it.
Tell me about a time you had to make value legible to senior leadership.	Ownership / Earn Trust	Accepting that the critique was about evidence, not effort; copying a trusted format; signing each definition with its owner; the review becoming the decision forum.	Never say "I invented the WBR."
Tell me about a time you said no to a stakeholder (Sales).	Have Backbone / Highest Standards	Six criteria published before wave 1; wave 3 held in public; held customers became the cleanest wave.	Do not call Sales wrong — they were right to want speed; the gate did the refusing.
Tell me about a time you chose the harder, honest number.	Earn Trust	The 99.4% three-touch week printed as a data miss; the 15-day active rule as the honest denominator.	Skip the Wilson-interval math unless asked; say "three touches is not a week."

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
How did you decide the customer was ready to launch? (Customer Obsession)	Customer Obsession	CSAT ≥ consignee average inside the gate; ~50-container calibration entry bar; 100 real containers × 7 checks before the first paying customer.	Do not claim customer-satisfaction dollars; none exist in canon.
How would you run a WBR for my team?	Functional — operating cadence	Copy a trusted format, freeze 5–7 definitions with owners and honest denominators, tag inputs to outputs, pre-decompose reds, let the review take the decision.	Never "$1.00 → $0.03"; never "70% baseline"; never "10×".
How would your wave machine apply to my world — placement / inbound? (transferability probe — public-profile inference)	Functional — transfer	The wave machine is graduated onboarding behind published criteria — the same shape as onboarding inventory into an IXD / crossdock program: a selection bar published before the first node, a calibration volume per node (~50 containers per client ≈ a trial volume per node), and a public hold when a node misses. Scale follows the gate, never the ask.	Do not lecture on her network; bridge in one sentence and hand it back with a question.
Your CTS is per container — mine is per node. Does the logic survive? (transferability probe)	Functional — transfer	Identical logic, different denominator: cost-to-serve per node = touches per unit through the node × cost per touch; the fix is still automation coverage and source quality, and the honest denominator is still defined before the metric. $0.66 → $0.03 is the container-grain instance of it.	Never quote her profile's $50MM / $80MM as if it were mine — those are her numbers, quoted for framing only.

DEEPENING S11 — FIVE FACETS, FOUR-TABLE MATH, BEHAVIORAL PACK, ANGLES AND TRAP DRILLS NEW

FIVE FACETS AT A GLANCE — the labeled structure the probing section below follows

1 · Data analysis	Cost-to-serve decomposed into touches (3.67 → 0.17); the 15-day active denominator; the three-touch week; wave-3 accuracy traced to one source; the pre-production evidence (500 containers in 20 minutes at 99.6%; dry run 100% processed, 86% tracked) and my own n = 300 sample design (user anchor).
2 · Solution design	Board-all vs gated waves; copy a trusted format vs invent; criteria published before wave 1; sample vs census; headcount vs automation as the scale lever.
3 · Math & data logic	Four tables: $0.66 / $0.18 = 3.67; about 95%; 9.7×; $30,240–$80,640; 80,000 × 3.5 min ≈ 2.6 FTE; the pre-production sample design n = 300 → ±1.6% (user anchor).
4 · Implementation	Waves 2 → 4-of-7 → 20+ with monthly GO / NO-GO; the Monday review; input owners across the nine teams; kill switches; the hand-off to the pipeline.
5 · Probe questions	Seven numeric probes plus three trap drills: direct dollars, "10×" and the FTE claim, and the separate ~$1.5M.

Facet 1 — Data analysis: what each analysis decided

ANALYSIS	DATA AND GRAIN	WHAT IT SHOWED	DECISION IT DROVE
Cost-to-serve decomposition	dollars per container ÷ $0.18 per interaction (record cross-walk)	$0.66 is ≈3.67 human touches; $0.03 is ≈0.17	automation coverage, not headcount, is the scale lever

ANALYSIS	DATA AND GRAIN	WHAT IT SHOWED	DECISION IT DROVE
Active denominator	active = cumulative inflow less containers 15 days past departed terminal, by week	cumulative counts hide a slowing program	review runs on active, not cumulative
Week-over-week instrument	(B − A) / A against ±5%	(21.9 − 40.0) / 40.0 = −45% → red; root cause a carrier format change	reds are decomposed before the meeting, measurement vs operations
Three-touch week	99.4% on N = 3 touches	a 95% interval on N = 3 is wider than the metric	printed as a data miss, not a result
Wave-3 accuracy by source	ETA accuracy per data source	the miss traced to one bad source	held in public; the held customers became the cleanest wave
Pre-production sampling	n = 300 at ≈98% expected accuracy (my sample design)	±1.6% at 95% confidence	a 1.5-month proof instead of 6 — my estimate; the separate ~$1.5M pre-production figure is a user anchor, not a program-document number

Facet 2 — Solution design: options weighed

QUESTION	OPTIONS	CHOSEN	WHY
Boarding pace	Board the whole pool now (Sales) · waves behind published criteria	Waves behind six criteria, published before wave 1	A free pilot spends engineering, data and ops before revenue; the rule does the refusing.
Review format	Invent a scorecard · copy the leadership review leadership already trusted	Copy the LSA format; freeze seven metrics with owners	Inventing would have spent credibility the program did not have.
Lever for scale	Add ops headcount · raise automation coverage	Automation 40% → 90%	Cost-to-serve is a touches problem: $0.66 / $0.18 = 3.67 touches.
Pre-production proof	Census over months · calibrated sample	Sample of 300 containers, ±1.6% at 95%	Big enough to certify the gate, small enough to afford — my estimate: 1.5 months instead of 6 (user anchor).
Bad week	Print 99.4% · print a data miss	Data miss	A number that cannot survive the next Monday teaches the VP the wrong thing.

Facet 3 — Math & data logic (four tables: Before · Fix substituted · After · Dollars)

Table 1 — Before: the problem in numbers

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Cost-to-serve	`$0.66 per container off seven pilots`	record	$0.66
2	Residual human touches	`$0.66 / $0.18 = 3.67 touches per container`	record cross-walk ($0.18 per eliminated interaction)	≈ 3.7 touches
3	Automation and accuracy	`coverage 40%; ETA accuracy 60%`	record	most containers still touched by hand

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
4	Customers vs target	`7 pilots against a target of 68; the program was to drop from #3 to #14 of 16`	record	value invisible to leadership

Table 2 — The fix: gates, honest denominators and the instrument, values substituted

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Launch gate volume	`100 real containers × 7 checks = 700 check results before the first paying customer`	record design; product mine	700 checks
2	Load proof	`500 containers in 20 min = 25 a minute; 498 / 500 = 99.6%`	record (500 / 20 min / 99.6%); arithmetic mine	25 / min · 99.6%
3	Honest denominator	`a 99.4% week on N = 3: Wilson lower bound 3 / (3 + 1.96²) = 0.44`	record decision (99.4% on three touches, Apple A2); the Wilson interval is my arithmetic	0.44 → data miss
4	Week-over-week rule	`(21.9 − 40.0) / 40.0 = −45% → beyond ±5% → red`	record: the weekly prints were 40.0% on 17 Jan and 21.9% on 31 Jan 2022 (Apple A2)	−45% → red
5	Pre-production sample	`1.96 × √(0.98 × 0.02 / 300) = 0.0158 = ±1.6 points; rollout proof 6 − 1.5 = 4.5 months saved`	user anchor (my sample design; GFiber v8 only — the program documents show 500 containers in 20 minutes at 99.6%, and an 86%-tracked dry run)	±1.6% · 4.5 months

Table 3 — After: before → after

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Cost-to-serve	`1 − $0.03 / $0.66 = 0.9545 → about 95%; $0.03 / $0.18 = 0.17 touches`	record endpoints; ratio mine	about 95% · 0.17 touches
2	Touches removed	`3.67 − 0.17 = 3.5 per container — about 95% of the touches`	record cross-walk; arithmetic mine	3.5 per container
3	Automation / accuracy	`40% → 90% = +50 points; 60% → 90% = +30 points`	record	+50 / +30 points
4	Customers	`68 / 7 = 9.71; zero rollbacks; no added ops headcount; 68 customers and 170 monthly users two months early`	record	9.7× (never rounded up)

Table 4 — The dollars: every multiplication shown (record vs modeled)

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Containers at the 32,000-shipment target	`32,000 × 1.5 = 48,000; 32,000 × 2.5 = 80,000; 32,000 × 4 = 128,000`	containers per shipment illustrative (1.5–4)	48K / 80K / 128K
2	Unit saving	`$0.66 − $0.03 = $0.63`	record endpoints	$0.63
3	Direct CTS dollars	`48,000 × $0.63 = $30,240; 80,000 × $0.63 = $50,400; 128,000 × $0.63 = $80,640`	modeled	$30K · $50K · $81K
4	Headcount never hired	`80,000 × 3.5 touches = 280,000 touches; × 1 min = 4,667 h; ÷ 1,800 h per FTE = 2.6 FTE (÷ 1,920 → 2.4)`	modeled: one minute per touch and 1,800 hours per FTE-year are assumptions	≈ 2.5 people (2.4–2.6)
5	The separate user anchor	`~$1.5M pre-production measurement saving: n = 300 → 1.5 vs 6 months`	user anchor (GFiber v8 only) — a separate figure, never added to CTS or the model	~$1.5M, never merged

Facet 4 — Implementation: the wave machine and its controls

WAVE	CLIENTS (RECORD)	ENTRY	GRADUATION / DECISION	TIMING (RECORD)
1	2 named pilots	~50-container calibration	six criteria; monthly GO / NO-GO	around Q4 2021
2	4 of a 7-client pool	~50-container calibration	six criteria; monthly GO / NO-GO	around Q1 2022
3	20+	~50-container calibration	held in public on an ETA-accuracy miss; held customers became the cleanest wave	around Q2 2022
Full	the pool to 68	graduated clients	rollout unlocked two months early off the review	H2 2022

Controls. Nine input owners each sign the definition they will be red against; reds are pre-decomposed with an owner and a dated fix; per-hop monitors and kill switches on the pre-production ingest; the manual pull is the review's source until the pipeline matches within 1% (S16-A). **Lean / Kaizen mapping.** The six criteria are standard work for onboarding; the hold on wave 3 is jidoka — stop the line when a quality criterion fails; the Monday review is the PDCA Check; "edits are the enemy" is the 2021 plan's own waste statement — every human correction is a defect, not a fix.

Facet 5 — Probe questions (numeric)

> **Why is the direct dollar figure so small?**
>
> Because the unit economics is the point: $0.63 saved on 48,000–128,000 containers is $30,240–$80,640, modeled on an illustrative containers-per-shipment. What it bought was 68 customers on the same ops team — about 2.5 people never hired, modeled — and a rollout unlocked two months early.

> **Prove the 2.5 people.**
>
> It is a model with two assumptions I name: 80,000 containers × 3.5 touches removed × one minute = 4,667 hours; at 1,800 hours a year that is 2.6 FTE, at 1,920 it is 2.4. I would replace the minute with the ticket-grain automation data.

> **Why ±1.6%?**
>
> That is my sample design, a user anchor — the program's own evidence was 500 containers in 20 minutes at 99.6% and a dry run at 100% processed, 86% tracked. n = 300 at about 98% accuracy: 1.96 × √(0.98 × 0.02 / 300) = 0.0158. Big enough to certify the gate, small enough to afford — it cut the rollout proof from 6 months to 1.5, which is the separate ~$1.5M pre-production estimate (user anchor), never merged with cost-to-serve.

> **Is it 10× or 9.7×?**
>
> 68 / 7 = 9.71. Say 7 to 68, or 9.7 times; no other multiple belongs in the room.

> **What does −45% week-over-week mean?**
>
> (21.9 − 40.0) / 40.0 = −45%, red against ±5%. The weekly prints were 40.0% on 17 January and 21.9% on 31 January 2022 (record); the root cause was a carrier format change — measurement, not operators.

> **How do you know a wave is ready?**
>
> Six criteria all pass — data quality at least 90%, ETA accuracy at least 80%, SLA 90% reviewed within 24 hours, at least 100 containers and 5 features, stability, CSAT at or above the consignee average — after a ~50-container calibration.

> **What would you change?**
>
> Start the review at kickoff instead of after the critique, and price the pipeline hand-off earlier — the pull stayed with me for months.

SENSITIVITY — CONTAINERS PER SHIPMENT (THE SOFT INPUT)

CONTAINERS PER SHIPMENT	CONTAINERS A YEAR	DIRECT CTS SAVING (× $0.63)	FTE-EQUIVALENT (ILLUSTRATIVE)
1.5 (low)	48,000	$30,240	1.6
2.5 (base)	80,000	$50,400	2.6
4.0 (high)	128,000	$80,640	4.1

Both columns are modeled on an illustrative containers-per-shipment; the record gives shipments, not containers. The ~$1.5M pre-production figure is excluded from every row.

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

> Honestly, the cost-to-serve number is a unit-economics result, not a big-dollar number: ninety-five percent off per container is measured, and at the thirty-two-thousand-shipment target it is only about fifty thousand dollars a year of direct cost — my model, on an illustrative container count. What it bought is scale: sixty-eight customers on the same ops team with zero rollbacks, about two and a half people we never had to hire — modeled — and a rollout unlocked two months early. The million and a half on the pre-production measurement path is a separate figure — my own estimate — and I keep it separate. So: the ninety-five percent and the seven-to-sixty-eight are record; every dollar except that one-and-a-half is my model.

IF CHALLENGED — THE FULL ANSWERS

"Your containers-per-shipment is a guess."

It is, and I said so: 32,000 shipments is a target, not a count, and it is shipments, not containers. At 1.5 to 4 containers per shipment the direct saving runs $30,240 to $80,640. I would pull the active-container count from the 15-day active rule the review already uses.

"Fifty thousand a year is small — why lead with it?"

Because it is honest, and the point was never the direct dollars: it was boarding 9.7 times the customers without 9.7 times the ops headcount.

"Where does the million and a half come from, then?"

The pre-production measurement path: 300 containers at ±1.6% proved the product in 1.5 months instead of 6. It is my estimate (a user anchor, not a program-document number), it is not cost-to-serve, and I never add it to the fifty thousand.

20-SECOND VERSION AND NACF BRIDGE

20-SECOND VERSION

At Flexport I owned the boarding process for Shipment Visibility: six published graduation criteria and a Monday input-output review took cost-to-serve from $0.66 to $0.03 per container while customers went from 7 to 68, with zero rollbacks and 68 customers and 170 monthly users landed two months early.

NACF BRIDGE — ONE SENTENCE

It is the shape of a network launch: onboard each node behind criteria published before the first one, calibrate on a trial volume, and hold a node in public when it misses — scale follows the gate, never the ask.

BEHAVIORAL PACK — FOUR QUESTIONS THIS STORY ANSWERS, EACH A SEPARATE 90-SECOND STAR FROM A DIFFERENT FACET

B1 · "Tell me about a time when you not only met a goal but considerably exceeded expectations. How were you able to do it? What challenges did you have to overcome?" AIQB: Deliver Results Q3 **Deliver Results** FACET: IMPLEMENTATION

Open (first two sentences): "Both public targets landed two months early with zero rollbacks — and the way they landed is the point: boarding went through six published criteria, not around them."

90-second STAR. **S** Seven pilots against public targets of 68 customers and 170 monthly active users (plus a 32,000-shipment target); Sales wanted the whole pool boarded at once. **T** Hit the targets without a rollback or added ops headcount. **A** Waves — 2, then 4 of 7, then 20-plus — each entering on a ~50-container calibration and graduating on six criteria published to Sales before wave 1, with a launch gate of 100 real containers across seven checks and a Monday review taking the rollout decision. **R** Customers 7 → 68, cost-to-serve $0.66 → $0.03, automation 40% → 90%, accuracy 60% → 90%; zero rollbacks.

Land: 7 → 68 (9.7×); 68 customers and 170 users two months early · **Pivot to NACF:** launching nodes in a network: published gates, calibrated volumes, a public hold when a node misses.

Do NOT say: "10×" or any other multiple; the $1.5M added to cost-to-serve.

B2 · "Give me an example of a tough or critical piece of feedback you received. What was it and what did you do about it?" AIQB: Earn Trust Q2 **Ownership** FACET: DATA ANALYSIS

Open (first two sentences): "Senior leadership told me the program was not demonstrating value and would drop from third to fourteenth of sixteen. I had been reporting activity, not evidence — and I accepted that first."

90-second STAR. **S** A program about to lose its funding slot because value was invisible. **T** Make value legible without arguing the critique. **A** I inventoried what leadership actually decides on, copied a review format they already trusted, froze seven metrics with owners who signed the definitions they would be red against, and ran the pull by hand every Monday for months. **R** The same critic steered the rollout by the review's numbers, and unlocked the 68-client rollout two months early.

Land: #3 → #14 of 16 → the VP unlocked the rollout · **Pivot to NACF:** owning a metric nobody owned: build it by hand first, automate it once the definitions are signed.

Do NOT say: that I invented the weekly review — I copied the LSA format.

B3 · "Tell me about a time when you had to balance the needs of the customer with the needs of the business. What did you do? What was the result?" AIQB: Customer Obsession Q8 **Customer Obsession** FACET: SOLUTION DESIGN

Open (first two sentences): "Wave three was held in public because ETA accuracy missed on one bad source. Sales wanted speed; the customers we held became the cleanest wave."

90-second STAR. **S** A free pilot where every boarded client cost engineering, data and ops before revenue. **T** Protect each client's first impression at scale. **A** Six criteria published before wave 1 — including CSAT at or above the consignee average — a ~50-container calibration on each client's own freight, and a hold on wave 3 traced to one bad source. **R** Zero rollbacks; the held wave became the cleanest.

Land: zero rollbacks; wave 3 held · **Pivot to NACF:** inbound readiness: do not take the first container until the node's criteria pass.

Do NOT say: that Sales was wrong — they were right to want speed; the gate did the refusing.

B4 · "Tell me about a time when you uncovered a significant problem in your team. What was it and how did you communicate it to your manager and other stakeholders? What did you do to address the problem?"

AIQB: Earn Trust Q6 **Earn Trust** FACET: MATH AND DATA LOGIC

Open (first two sentences): "One week showed ninety-nine point four percent — on three touches. A 95% confidence interval on three is wider than the metric, so I printed a data miss instead."

90-second STAR. **S** A flattering week landing just before a funding decision. **T** Keep the review credible. **A** I computed the interval — Wilson lower bound 0.44 on N = 3 — and held the review to the 15-day active denominator; the week was printed as a data miss. **R** A number that survived the next Monday; the review was trusted twice.

Land: 99.4% on N = 3 → data miss · **Pivot to NACF:** any capacity report: a rate on a tiny denominator is not a result.

Do NOT say: the Wilson math unless asked — say "three touches is not a week".

SAME STORY, THREE ANGLES — THREE CARDS, THREE OPENERS, THREE METRICS, THREE LPS

Data / analytical angle **Dive Deep**

Opener: "Cost-to-serve was sixty-six cents a container — which is three and two-thirds human touches. The program was a touches problem, not a headcount problem."

Headline metric: $0.66 / $0.18 = 3.67 → 0.17 touches

- Decompose dollars into touches with the record cross-walk.
- Active denominator: cumulative inflow less containers 15 days past departed terminal.
- WoW rule: −45% is red; root cause a carrier format change.
- Say "modeled" on every dollar.

Conflict / influence / backbone angle **Have Backbone; Disagree and Commit**

Opener: "Sales wanted the entire pool boarded at once; I published the gates to Sales before wave one, so when wave three was held, it was the rule firing — not me."

Headline metric: six criteria; wave 3 held

- The rule did the refusing; no one was called wrong.
- The held customers became the cleanest wave.
- The trade: boarding speed for a rollout that never rolled back.
- Leadership took the decision in the Monday review.

Honest failure-and-learning angle **Learn and Be Curious**

Opener: "I had been reporting activity, not evidence — leadership said so, and they were right. The review should have started at kickoff, not after the critique."

Headline metric: #3 → #14 of 16

- What I got wrong: measuring effort instead of outcomes.
- What I changed: seven frozen definitions, input → output tagging.
- What I would do differently: kickoff review; earlier pipeline hand-off.
- What held: zero rollbacks.

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS

"Customers 7 to 68 — that's a 10× result?"

Numeric answer. 68 / 7 = 9.71. The only multiple to say is 9.7× — or just 7 to 68. Rounding up to 10× overstates a record number by 3%.

Say exactly: "Seven to sixty-eight — nine point seven times, and I won't round that up."

"You said two and a half people never hired. Show me."

Numeric answer. 80,000 containers × 3.5 touches removed × 1 minute = 4,667 hours; ÷ 1,800 h = 2.6 FTE (÷ 1,920 h = 2.4). Modeled: containers per shipment, one minute per touch and the hours per FTE are my assumptions; the record is zero added ops headcount at 68 customers.

Say exactly: “It's modeled: about two and a half people on an illustrative container count and a minute a touch — the record is that headcount didn't grow.”

"So the saving is $1.5M plus $50K?"

Numeric answer. No. The ~$1.5M is the pre-production measurement saving (n = 300 → ±1.6%, 1.5 vs 6 months) — my estimate and a user anchor, kept separate. The $50,400 is modeled direct cost-to-serve at 80,000 containers. They never add.

Say exactly: “They're separate. The million and a half is my estimate of the pre-production proof path, kept separate; the fifty thousand is my model of direct cost-to-serve.”

S11-A — Flexport — The Monday review as an analysis: taking a 22× cost-to-serve drop apart (6.0× coverage × 3.67× touch efficiency), with honest denominators, seven frozen metrics and one discarded week NEW

LPs this story can serve here: Dive Deep (primary) · Insist on the Highest Standards · Earn Trust · Are Right, A Lot (backup)
Process family: Plan / Deliver — operating cadence, measurement design and cost-to-serve analysis; weekly business review (WBR)

LEADERSHIP PRINCIPLES THIS STORY CARRIES — ONE-LINE PROOF SENTENCE EACH

Dive Deep I took $0.66 → $0.03 apart: 22.0× = 6.0× fewer containers needing a human (60% → 10%) × 3.67× fewer touches on each one that did — and showed the split depends on the order you attribute it.

Insist on the Highest Standards Seven metric definitions frozen and signed by the owners who would be red against them; a 15-day active denominator; a truncated 99.4% week (three touches) thrown out.

Earn Trust I printed a data miss instead of a flattering number, because three touches is not a week.

Are Right, A Lot Every red was decomposed before the meeting; a −45% week (40.0% on 17 Jan to 21.9% on 31 Jan 2022, record) traced to a carrier format change — measurement, not operators — and the same number was checked the next Monday.

Honesty label. Same program family as S11, a different cut: S11 is the boarding process and its gates; this story is the measurement system and the analysis behind it. The review format was copied from the LSA weekly review, not invented, and I built it by hand every Monday for months. The 22× decomposition and the 56% / 44% attribution are *my model* on record endpoints — they assume touches fall only on non-automated containers, and I say the split is a convention, not a measurement (the order-dependence is shown in Table 3). The week-over-week values (40.0% on 17 Jan → 21.9% on 31 Jan 2022), the three grains (19.4% · 54.1% · 40.2% → 69.2%) and the discarded 99.4% week are **record** from my own review workbook (Apple v11 A2, extract SV_28.xlsx); the hand-built review ran for months. The real LSA weekly-review workbook (Table 5) is the format I copied — its FFA tab is another team's slide, used here to show the mechanics on real data, not as my program's numbers. An early draft note in the source folder carries much larger growth multipliers for customers and volume — they conflict with canon (7 → 68 = 9.7×) and are **never said**.

WHAT THE RECORD SAYS ABOUT THE REVIEW (FROM THE PROGRAM DOCUMENTS; RECORD-FROM-DOCS)

The format. The LSA weekly-review instructions separate *output* from *input* metrics; a week runs Monday–Sunday; the view carries five consecutive weeks plus months; week-over-week is the relative change (B − A)/A; green is favorable beyond 5%, red unfavorable beyond 5%. RECORD-FROM-DOCS

What the program asked of it. The Feb 1, 2022 E-Team takeaways name Goal 1 as lowering cost-to-serve, ask for cost-to-serve measured for 3PL + 4PL versus 4PL only, have the visibility team publish its own weekly review, and set the improvement priority rule: rank carriers, terminals and milestones on the two priority lanes by cost-to-serve reduction first, ease of getting the data second. RECORD-FROM-DOCS

What the review ran on. The BRD names the seven metrics and the as-is: a manual Zendesk pull matched to a manual container pull in Google Sheets, 1.5–2 hours per week-over-week snapshot (a BRD measure; my own account is "about four hours a week at its worst" — two different measures, never stacked). My review workbook (Apple A2) is the container-status-history extract SV_28.xlsx — 10,289 events, week ending 28 Feb 2022. RECORD-FROM-DOCS

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. Flexport's visibility program was being judged by leadership that said it was not demonstrating value, and the only instrument was a spreadsheet I stitched from four systems every Monday. Cost-to-serve was $0.66 a container; nobody could say whether it would fall because automation covered more containers or because each human touch got cheaper, and one flattering week could steer a rollout. **Task.** As program owner, make the numbers decision-grade. **Action.** I copied the LSA weekly review's mechanics — Monday-to-Sunday weeks, five weeks in view, week-over-week as (B − A)/A, red or green beyond ±5% — froze seven metrics with owners who signed the definitions they would be red against, tagged every input to the output it moves, and fixed the denominator: active is the cumulative inflow less containers 15 days past departed terminal. Then I took the headline apart: $0.66 to $0.03 is 22×, which is 6× fewer containers needing a human — 60% down to 10% — times about 3.7× fewer touches on each one that still did. When a week printed 99.4% on three touches I discarded it, because a 95% interval on three is 44% to 100%. **Result.** Primary metric: cost-to-serve $0.66 → $0.03 per container — about 95% — across customers 7 → 68, with every red arriving with an owner and a dated fix — and the same seven definitions now live in code.

SAFE-SAY — TWO SENTENCES TO SAY EXACTLY

Most attackable number. “Cost-to-serve went from sixty-six cents to three cents a container — about ninety-five percent. The split into six-times coverage and three-and-two-thirds touches is my model on those two record endpoints, and I call it a convention, not a measurement.”

“What's your source for that?” “The endpoints and the weekly prints come from the review workbook I built — the container-status extract — and from the program's own documents; the split and the sample-size arithmetic are mine, and I label them modeled.”

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — The program had public targets — 68 customers and 170 monthly active users (both landed two months early) and a 32,000-shipment target I managed toward — and leadership that said value was not legible; it was about to drop from #3 to #14 of 16 initiatives. The instrument was my Monday spreadsheet: four systems (tickets, container pulls, platform data, Jira), about four hours a week at its worst, one person who could break it. The analysis problem underneath had three parts: a headline that moved ($0.66 → $0.03) with no explanation of *what* moved it; denominators that could flatter or flatten a week; and small-N weeks that could mislead a VP.

T — Own the measurement design and the analysis: define what is measured, at which grain, against which denominator, and what the number must be able to explain — so leadership could steer rollout pace and funding off it.

Baselines on the table: CTS $0.66/container (≈3.7 touches at the record $0.18 per interaction) · automation 40% · ETA accuracy 60% · customers 7 · review built by hand — about four hours a week at its worst · seven metrics · five Mon–Sun weeks in view · ±5% week-over-week rule.

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery** — documented the as-is (four systems, Sheets, a person-dependent manual build); asked what leadership decides on (rollout pace, funding) and wrote the questions the review must answer weekly; chose the LSA review as the pattern to copy. *Exit bar:* leadership agrees the weekly questions; each input has a named owner.
- **Plan & Design** — froze seven metric definitions (coverage auto, coverage with human, tickets, tickets per active container, 4PL SLA %, 3PL SLA %, delta); input→output tagging; the ±5% week-over-week rule; the 15-day active denominator; a parking lot for new metrics. *Exit bar:* every owner signs the definition they will be red against; first Monday deck dry-run.
- **Build & Test** — built the deck by hand every Monday; pre-decomposed every red into source, definition or operator before the meeting; enforced the data-honesty rule (a truncated week is a data miss, not a result); tied Jira

blocker/critical trends to the input metrics. *Exit bar:* two consecutive Mondays where every red arrives with an owner and a dated fix, and the number verifies the following Monday.

- **Cutover & Go-Live** — the Monday review became the forum where rollout decisions were taken; waves boarded only through the published criteria; the decomposition went into the deck so leadership could see which lever moved cost-to-serve. *Exit bar:* the VP takes the rollout decision in the room off the numbers.
- **Hypercare / Close** — discarded the flattering 99.4% three-touch week and printed a data miss; moved the definitions into code with the Snowflake pipeline (S16-A) so the review no longer depended on one person. *Exit bar:* same seven numbers within 1% for consecutive weeks; the critic steers by them.

Influence and ownership. Mine: the diagnosis, the seven definitions, the denominator rule, the decomposition, the data-honesty rule and the Monday build. The input owners — Data Services, Support, GTM and the engineering teams — signed their own definitions and carried their own reds; the VP decided in the room. The format came from the LSA review.

> **Designed the process; others own it now.** I designed the definitions, the denominator and the reading rules; the owners run their lines, and the pipeline (S16-A) carries the definitions in code. **Trade-off put to leadership.** Coverage of the page (every metric anyone wanted) versus stability of the page (seven that never change definition) — I recommended stability and gave the rest a parking lot.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY (RECORD VS MODELED LABELED)

- **$** — cost-to-serve $0.66 → $0.03 per container (record; about 95%); direct dollars ≈$50K/yr *modeled* at the 32,000-shipment target on an illustrative 2.5 containers per shipment; ≈$21K/yr of by-hand review labor *modeled* (≈4 h/wk at its worst, at $100/h — an upper bound); the ~$1.5M pre-prod figure (S11, user anchor) stays separate.
- **#** — seven frozen metrics, each with a named owner; customers 7 → 68 (9.7×) with zero rollbacks; 68 customers and 170 monthly users landed two months early (record); the 32,000-shipment figure is a target, not a result.
- **%** — automation 40% → 90%; ETA accuracy 60% → 90% (record); coverage-versus-touch-efficiency split ≈56% / 44% (modeled).
- **Time** — by hand for months — about four hours a week at its worst — until the pipeline matched within 1% (record, Apple A1/A2); rollout unlocked two months early off the review (record).
- **Customer** — the review carried the graduation criteria and CSAT ≥ consignee average into the rollout decision — the customer lens was on the Monday page (record).
- **Quality** — a truncated 99.4% week (three touches) discarded and printed as a data miss; a −45% week (40.0% → 21.9%, 17 → 31 Jan 2022) traced to a carrier format change, not operators; definitions frozen and later moved into code (record).

L6 LEVEL EVIDENCE — this story against the Amazon L6 functional rubric; every line is this story's record or labeled model

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	No product-analytics function existed. I defined the questions, the metrics and the denominators, and chose the owners — then explained the headline, not just reported it.
Scope & influence	Seven owners across Data Services, Support, GTM and engineering signed definitions; a VP decided in the room — influence one to two levels up from a program seat.
Execution trade-off + mechanism others now own	Stability over coverage: seven metrics, a parking lot, no mid-flight redefinition. Mechanism others own: the frozen definitions, the 15-day rule and the ±5% rule, now in code (the Snowflake pipeline, S16-A).
Impact (long-term)	A cost-to-serve story leadership could act on: which lever moved it, which to fund next, and a rollout paced by evidence.
Process improvement (standard work institutionalized)	Standard work for the weekly review: frozen definitions, honest denominators, input→output tags, every red decomposed with an owner and a dated fix, verified next Monday (PDCA).
Complexity & consensus	Owners wanted their metric on the page; I held seven and gave them a parking lot. Sales wanted to board everything; the review carried the gates.
Root cause at scale	Reds traced to source, definition or operator before escalation — the −45% week was a carrier format change; the 99.4% week was three touches.

FIVE FACETS AT A GLANCE — the labeled structure the probing section below follows

1 · Data analysis	Three grains from SV_28.xlsx (event 19.4% · ticket queue 54.1% · weekly stock 40.2% → 69.2%); ticket ↔ container join; cuts by coverage, SLA and 4PL vs 3PL; what it revealed: a two-lever decomposition, a measurement-caused red, a small-N week.
2 · Solution design	Copy the LSA format vs invent; freeze seven vs expand; 15-day active vs cumulative denominator; ±5% week-over-week vs raw levels.
3 · Math & data logic	3.67 touches → 22.0× = 6.0× × 3.67×; order-dependent attribution ($0.55/$0.08 vs $0.48/$0.15) → fair split 56/44; Wilson interval on N = 3 → [0.44, 1.0]; $50.4K + $20.8K = $71.2K modeled.
4 · Implementation	Monday standard work: build, decompose, owner + dated fix, verify next Monday; owners sign; parking lot; hand-build for months, then pipeline parity within 1%.
5 · Probe questions	Six numeric probes plus three trap drills; Table 5 recomputes the real LSA workbook (relative vs absolute WoW, a constant "weekly" metric, a dubious-data flag).

PROBING — FIVE FACETS, THEN THE FULL DRILL

Facet 1 — Data analysis (what data, grain, joins, cuts, what it revealed)

Grain and joins. The instrument was the container-status-history extract (SV_28.xlsx, week ending 28 Feb 2022): the grain was the container-status *event*, not the shipment, rolled up to a weekly stock. Three grains, one formula family, never blended: **event** 1,991 of 10,289 human-touched = 19.4%; **ticket queue** 538 auto vs 456 human = 54.1% auto; **weekly stock** (the headline) 40.2% on 13 Dec 2021 → 69.2% on 21 Feb 2022 RECORD (APPLE V11 A2). Sources: Zendesk tickets (a ticket is created when Visibility fails to auto-initiate tracking), the container pull from Crux, platform tracking data and Jira blocker/critical counts RECORD-FROM-DOCS. The join is ticket ID ↔ container number; tickets carried no container ID, so the first versions matched by hand — the gap S16-A closes with a cross-reference table.

Cuts. Coverage automated vs with human input; tickets and tickets per *active* container; SLA for 4PL vs 3PL and the delta between them; 3PL + 4PL vs 4PL only (the E-Team ask). Every cut is an output metric tagged to the inputs that move it.

What the analysis revealed. (1) The headline was two multiplied levers: 22.0× = 6.0× (containers needing a human 60% → 10%) × 3.67× (touches per touched container 6.11 → 1.67) — a *modeled* split on record endpoints. (2) The attribution is order-dependent, so I report the fair split (average of both orders): ≈56%

coverage, ≈44% touch efficiency. (3) A −45% week-over-week red — 40.0% on 17 Jan to 21.9% on 31 Jan 2022 — traced to a carrier format change, measurement not operators RECORD. (4) The 21 Feb print of 69.2% moved with the denominator (active book 287 → 546 the week a big client's 283 containers hit), and the 28 Feb print of 99.4% rested on three touches — a truncated week, discarded RECORD.

CUT	QUESTION IT ANSWERS	INPUT OWNER TYPE
Coverage auto vs with human	Is the machine doing the work, or the desk?	Data Services / engineering
Tickets per *active* container	Is cost-to-serve falling per unit of live freight?	Support / Data Services
4PL vs 3PL SLA and delta	Do we serve non-Flexport freight as well as our own?	Visibility / Data Services
Jira blocker/critical WoW	Which defects explain the reds?	Engineering managers

Facet 2 — Solution design (options considered, chosen design, why)

DESIGN QUESTION	OPTIONS WEIGHED	CHOSEN	WHY (RECORD UNLESS MARKED)
Review format	Invent a new format · copy the LSA weekly review	Copy	It already had leadership's trust; inventing one would have spent credibility I did not have (canon).
Metric set	Everything anyone asks for · freeze seven + parking lot	Freeze seven	A number that changes definition cannot steer a rollout — stability over coverage (canon).
Denominator	Cumulative containers · touched this week · active = cumulative inflow less containers 15 days past departed terminal	15-day active	The honest denominator for per-container rates; cumulative flatters. Defined in the workbook as cumulative inflow less containers 15 days past departed terminal (Apple A2) VERIFY-WITH-RAJESH · V2
Reading rule	Raw levels · week-over-week (B − A)/A with ±5% red/green	WoW ±5%	Same rule as the review leadership already read; a red needs an owner and a dated fix (canon).
Small weeks	Print every week · mark insufficient data	Mark a data miss	The interval on three touches is wider than the band the number is read against.

Facet 3 — Math & data logic (four tables: Before · Fix substituted · After · Dollars)

Table 1 — Before: the problem in numbers

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Touches per container at the baseline	`$0.66 / $0.18 = 3.67`	record; $0.18 per interaction is the record cross-walk	≈3.7 touches per container
2	Containers needing a human	`1 − 0.40 = 60%`	record (automation coverage 40%)	60%
3	Touches per human-needed container	`3.67 / 0.60 = 6.11`	modeled — assumes every touch lands on a non-automated container	≈6.11 touches
4	By-hand build time	`about four hours a week at its worst (my own account); the BRD as-is is 1.5–2 h per snapshot — a different measure, not stacked`	record (Apple A1/A2); BRD figure labeled record-from-docs	≈4 h/wk at its worst

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
5	Three grains, three honest numbers	`event: 1,991 / 10,289 = 19.4% human-touched (80.6% auto); ticket queue: 538 / (538 + 456) = 54.1% auto; weekly stock: 40.2% (13 Dec) → 69.2% (21 Feb)`	record — Apple A2, extract SV_28.xlsx; the ratios are my arithmetic	one formula family, three grains — never blended
6	The denominator moved under the headline	`active book 287 → 546 (21 Feb, a big client's 283 containers hit): (546 − 287)/287 = +90.2%`	record inputs (Apple A2); the ratio is my arithmetic	a rate can jump because the base did

Table 2 — The fix: the instrument and its rules, values substituted

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Seven frozen metrics	`2 coverage + 2 cost-to-serve + 3 timeliness = 7`	record (BRD metric list)	7 definitions, 7 owners
2	Week-over-week rule	`(B − A)/A = (21.9 − 40.0)/40.0 = −45% → |−45%| > 5% → red`	record: the ±5% rule is the LSA review (Instructions row 9); 40.0% on 17 Jan and 21.9% on 31 Jan 2022 are the printed weekly values (Apple A2)	red; root cause a carrier format change
3	Small-N rule	`Wilson lower bound for 3 of 3 = 3 / (3 + 1.96²) = 0.44 → interval [0.44, 1.00]`	record: 99.4% on three touches (Apple A2); the Wilson interval is my arithmetic	width 0.56 vs a 0.10-wide band
4	Sample floor I would write down now	`n = 1.96² × 0.90 × 0.10 / 0.05² = 138.3 → 139 active containers for ±5 points at 90%`	illustrative threshold — not in the record (what I would add)	≈139 containers
5	Honest denominator	`Active_d = cumulative inflow − containers 15 days past departed_terminal; rate = human-touched containers ÷ Active_week; automation = 1 − rate`	record rule (Apple A2)	every per-container metric

Table 3 — After: the metric, before → after, and the decomposition

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Cost-to-serve	`1 − $0.03/$0.66 = 1 − 0.0455 = 0.9545 → I say "about ninety-five percent"`	record endpoints (Apple A1/A2); ratio mine	$0.66 → $0.03, about 95%
2	Coverage lever	`human-needed share 60% / 10% = 6.0×`	record endpoints (40% → 90%)	6.0×
3	Touch-efficiency lever	`6.11 / 1.67 = 3.67× (1.67 = $0.03 / $0.18 / 0.10)`	modeled	3.67×
4	Identity check	`6.0 × 3.67 = 22.0 = $0.66 / $0.03`	arithmetic	22.0×
5	Attribution, coverage first	`$0.66 − 0.10 × 6.11 × $0.18 = $0.66 − $0.11 = $0.55 from coverage; $0.11 − $0.03 = $0.08 from touches`	modeled	$0.55 / $0.08
6	Attribution, touches first	`$0.66 − 0.60 × 1.67 × $0.18 = $0.66 − $0.18 = $0.48 from touches; $0.18 − $0.03 = $0.15 from coverage`	modeled	$0.48 / $0.15
7	Fair split (average of both orders)	`coverage ($0.55 + $0.15)/2 = $0.35; touches ($0.08 + $0.48)/2 = $0.28; $0.35 / $0.63 = 56%, $0.28 / $0.63 = 44%`	modeled	56% / 44%

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
8	Scale	`68 / 7 = 9.7×; automation 40% → 90%; accuracy 60% → 90%; 170 monthly users is the public target, landed`	record	9.7× — the only multiple to say

Table 4 — The dollars, every multiplication shown

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Unit saving	`$0.66 − $0.03 = $0.63 per container`	record endpoints	$0.63
2	Containers per year at the 32,000-shipment target	`32,000 × 2.5 = 80,000 (range 48,000–128,000 at 1.5–4.0)`	the shipment count is a target, not an outcome; containers per shipment illustrative	80,000
3	Direct cost-to-serve saving	`80,000 × $0.63 = $50,400`	modeled	≈$50K/yr
4	Split by the fair attribution	`80,000 × $0.35 = $28,000 (coverage); 80,000 × $0.28 = $22,400 (touch efficiency)`	modeled	$28,000 / $22,400
5	Review labor by hand	`4 h/wk × 52 = 208 h; 208 × $100 = $20,800 ($16,640 at $80; $24,960 at $120)`	modeled; 4 h/wk is the at-its-worst figure, so an upper bound; rate is a benchmark range	≈$21K/yr
6	Total modeled run-rate	`$50,400 + $20,800 = $71,200`	modeled — master sensitivity base ≈$71K	≈$71K/yr
7	One-time revenue pull-forward (excluded from the run-rate)	`61 × $25,000 × 2/12 = $254,167`	modeled; ARR per customer is an illustrative benchmark; the pilot itself is free	≈$254K one-time

Table 5 — The review format run on a real workbook: LSA WBR 2022, FFA tab (my pandas / openpyxl recompute; the FFA slide is another team's, used to show the mechanics)

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Exceptions per shipment, Wk 35 → Wk 1	`(2.900821 − 4.068702) / 4.068702 = −28.7% (lower is better, so favorable)`	record: sheet FFA row 11, cols Wk 35–Wk 1; arithmetic mine	−28.7% in 18 weeks
2	Same metric, monthly view	`Apr 6.0 → Sep 4.0: (4.0 − 6.0) / 6.0 = −33.3%`	record: FFA row 11, monthly columns	−33.3%
3	Red / green weeks under the ±5% rule	`over the 18 week-over-week steps: unfavorable (> +5%) = 1, favorable (< −5%) = 4, inside the band = 13`	my recompute of FFA row 11 under Instructions row 9	1 red · 4 green · 13 quiet
4	The holiday week	`import-partner on-time share Wk 51 → Wk 52: (0.290 − 0.459) / 0.459 = −36.8% → red; Wk 52 → Wk 1: (0.506 − 0.290) / 0.290 = +74.5%`	record: FFA row 5; the owner's callout attributes Wk 52 to the holiday season	a red that arrives with a cause
5	Mean with and without the holiday week	`nine weeks: 4.2785 / 9 = 47.5%; without Wk 52: (4.2785 − 0.290) / 8 = 49.9%`	record inputs FFA row 5 (Wk 45–Wk 1); mean mine	47.5% vs 49.9%
6	Written rule vs printed column	`the Instructions say WoW = (B − A)/A; the WoW cell for Wk 52 → Wk 1 prints 0.216 = 0.506 − 0.290 — an absolute difference; under the rule it is +74.5%`	record: Instructions row 8 and FFA row 5 WoW cell; my observation	definition drift to flag, not to fix silently
7	A "weekly" metric that never moves	`import tasks structured into work items = 0.1346 in all 19 weeks; 7 / 52 = 0.1346`	record: FFA row 12; the 7 and 52 are my inference, the sheet does not say	static, not weekly — mark it

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
8	Data the owner flagged themselves	`notification read-rate Wk 43 → Wk 1: (0.050 − 0.0725) / 0.0725 = −31.0%, beside the sheet's own note: "data looks dubious and will double check"`	record: FFA row 16 and its note; arithmetic mine	a data miss until checked — the same rule as the 99.4% week

The ~$1.5M pre-production measurement saving (S11) is a separate user-anchor figure and is excluded from every row above. Automation is 40% → 90%; the loop packet's "60 → 97" is wrong (§1.3) — do not mix them in the room.

Facet 4 — Implementation (phases, owners, rollout, cutover, controls, risks)

CONTROL	STANDARD WORK	OWNER	LEAN / KAIZEN WORD
Definitions	Seven written definitions, signed, frozen; new metrics enter a parking lot, never the page	Each input owner	Standard work
Weekly build	Pull four systems → join ticket ↔ container → seven metrics on the 15-day active base → WoW ±5%	Me, by hand, then the pipeline	Takt: the Monday cadence
Red handling	Decompose to source / definition / operator before the meeting; owner + dated fix; verify the same number next Monday	Metric owner	Root cause (5 Whys), PDCA
Data honesty	A truncated or tiny-N week is a data miss, never a result	Me	Jidoka — stop the line on bad data
Hand-off	Pipeline parity within 1% for consecutive weeks, then retire the manual build (S16-A)	Infra + me	Remove waste (motion) and the single point of failure

Risks and mitigations. Measurement-caused reds (decompose first); a flattering wrong number (data-honesty rule); a single point of failure (the manual review); an expanding page (parking lot). **Rollout of the review itself:** dry-run deck → two consecutive clean Mondays → the VP takes a decision in the room → the review becomes the standing forum. A review that skips a week teaches leadership it can be skipped, so it ran every Monday.

Facet 5 — Probe questions (hardest follow-ups, numeric answers)

> **Is the 6.0× / 3.67× split real, or an artifact of your assumption?**
>
> It is a model, and I say so. The endpoints are record: $0.66 → $0.03 and coverage 40% → 90%. The split assumes every touch lands on a non-automated container; if exception handling touches automated containers too, the touch-efficiency lever is understated. The honest convention is the average of both attribution orders — 56% coverage, 44% touches — and the order-dependence itself (coverage's share runs 24%–87%) is why I call it a convention, not a measurement.

> **How do you know the −45% week was not operators?**
>
> Because I decomposed it before the meeting: source, definition, operator, in that order. The drop traced to a carrier format change — measurement. The owner took a dated fix and I looked at the same number the next Monday. The weekly prints were 40.0% on 17 Jan and 21.9% on 31 Jan 2022; the arithmetic is (21.9 − 40.0)/40.0 = −45%.

> **Why a 15-day active window, and what would change it?**
>
> It is the honest denominator for per-container rates — cumulative containers would let the base swamp the signal — in the real extract the active book went 287 → 546 in the week one big client's 283 containers hit, and the headline moved from the low 40s to 69.2% with it. Fifteen days past departed terminal was frozen with the owners. What would change it: showing the rate at 10, 15 and 30 days and freezing the window where the rate stops moving VERIFY-WITH-RAJESH · V2.

Three touches — why discard instead of caveat?

Because the interval was wider than the band. At 3 of 3 the 95% Wilson interval is 0.44 to 1.00 — 0.56 wide — against a ±5% (0.10-wide) red/green band. A number you cannot read against its own threshold is not a reading. To read a rate to ±5 points at 90% you need about 139 active containers.

You froze seven metrics. What did that cost?

Coverage of the page — engineering wanted more end-to-end input metrics, and the review parked them. The trade was stability: a number that changes definition cannot steer a rollout. The parking lot was real, and the pipeline (S16-A) is where the extra inputs could be added without touching the seven.

What decisions did the review actually change?

Three, all record: waves boarded only through the published criteria; wave 3 held in public on an ETA-accuracy miss traced to one bad source; the VP unlocked the 68-client rollout two months early off the review's numbers. The E-Team's improvement rule — rank by cost-to-serve reduction first, ease second — is the same Pareto the reds were sorted by.

BUSINESS IMPACT MODEL — KPI TREE

```
Leadership steers rollout pace and funding off a number that survives the next Monday
+- OUTPUT  cost-to-serve per container   $0.66 -> $0.03   (record, about 95%)   22.0x
|    +- INPUT  containers needing a human   60% -> 10%    (coverage 40% -> 90%, record)   6.0x
|    +- INPUT  touches per touched container 6.11 -> 1.67 (modeled)                        3.67x
|    +- fair split of the $0.63 saving: coverage ~56% / touch efficiency ~44% (modeled)
+- OUTPUT  ETA accuracy 60% -> 90%; customers 7 -> 68 (9.7x)   (record)
+- TAGS    Jira blocker/critical trend  <->  the input metric it explains
+- DENOM   active = inflow less containers 15 days past departed terminal; tiny-N weeks = data miss
(loop)   red -> owner -> dated fix -> same number verified next Monday -> trust -> decision taken in the
room
```

SOLUTION FLOW

```
Sun night   pull 4 systems (tickets, containers, platform, Jira)
   -> join ticket <-> container (xref until the real key exists)
   -> 7 metrics on the 15-day active base, container-week grain
   -> WoW = (B - A)/A ; flag beyond +/-5%
   -> decompose each red: source? definition? operator?   [5 Whys]
   -> owner + dated fix   -> Monday review: decision taken in the room
   -> next Monday: same number verified   [PDCA: Check / Act]
   -> pipeline parity within 1% for consecutive weeks -> manual build retired
```

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Containers per shipment (illustrative)	1.5	2.5	4.0
Containers per year at 32,000 shipments	48,000	80,000	128,000
Direct saving ($0.63 × containers)	$30,240	$50,400	$80,640
Review labor by hand ($80 / $100 / $120 per hour × 208 h)	$16,640	$20,800	$24,960
Total modeled $/yr	≈$47K	≈$71K	≈$106K

Revenue pull-forward ($254K) is one-time and the ~$1.5M pre-prod estimate is a separate user anchor; both are excluded from the run-rate.

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

Cost-to-serve fell from sixty-six cents to three cents a container — twenty-two times. When I took it apart it was two levers multiplied: six times fewer containers needing a human, sixty percent down to ten, and about three and two-thirds times fewer touches on each one that still did. That split is my model — it assumes the touches fall on the non-automated containers — and the attribution depends on the order you take it, so I report the average, roughly fifty-six percent coverage and forty-four percent touch efficiency, and I call it modeled. At the thirty-two-thousand-shipment target the direct saving is about fifty thousand dollars a year on an illustrative container count, plus about twenty-one thousand of review labor I stopped doing by hand — both modeled. What is record is the sixty-six cents, the three cents and seven to sixty-eight; what the review added is that every red arrived with an owner and a dated fix, and that when a week printed ninety-nine point four percent on three touches I printed a data miss instead.

IF CHALLENGED — THE FULL ANSWERS

"Your 22× decomposition is just algebra."

The product identity is algebra; the analysis is knowing it needs an attribution convention. If touches per touched container had stayed flat, the whole result would have been coverage; because both moved, the order matters, so I show both orders and report the average. The use is practical: it tells the review which lever to fund next.

"Why throw out a number that looked good?"

Three touches gives an interval of 44% to 100% — wider than the ±5% band the review reads against. Printing it would have taught the VP a number that could not survive the next Monday, and a review that flatters once is not trusted twice.

"An early note claims a far bigger growth multiple than 7 → 68. Which is it?"

The record is 7 → 68, 9.7×, against public targets of 68 customers and 170 monthly active users — both landed two months early — and a 32,000-shipment tracked target. The larger multiples are from an early draft note and are not canon; I do not use them.

20-SECOND VERSION AND NACF BRIDGE

20-SECOND VERSION

At Flexport I ran the weekly review that steered a visibility rollout: seven frozen metrics, a 15-day active denominator, ±5% red/green. I took the 22× cost-to-serve drop apart — 6× fewer containers needing a human, 3.7× fewer touches on each — and threw out a 99.4% week built on three touches.

NACF BRIDGE — ONE SENTENCE

The same review shape runs an inbound network — doors × hours × unload rate on one side, UPH and cubic fill on the other, each with a frozen weekly definition — so when door utilization crosses the ~85% knee or weeks-of-cover leaves its 2–4 week band, the red arrives with an owner, a dated fix and an honest denominator (doors in use, not doors installed).

BEHAVIORAL PACK — FOUR QUESTIONS THIS STORY ANSWERS, EACH A SEPARATE 90-SECOND STAR FROM A DIFFERENT FACET

B1 · "Tell me about a problem you had to solve that required in-depth thought and analysis. How did you know you were focusing on the right things? What was the outcome? Would you have done anything differently?" AIQB: Dive Deep Q3 **Dive Deep** FACET: DATA ANALYSIS

Open (first two sentences): "A cost-to-serve number fell ninety-five percent and nobody could tell me why, so I took it apart. It was two multiplied levers, not one."

90-second STAR. S Leadership doubted the program, and the headline was $0.66 → $0.03 per container. **T** Explain what moved it, so the review knew what to fund next. **A** I converted dollars to touches at the record $0.18 per interaction — 3.67 down to 0.17 — then split coverage (containers needing a human, 60% → 10%, 6.0×) from touches per touched container (6.11 → 1.67, 3.67×). I noticed the attribution changes with order — $0.55/$0.08 coverage-first, $0.48/$0.15 touches-first — so I reported the average, 56/44. **R** The split was modeled and I said so; the review had a shared way to talk about where the next fix should go, and the record endpoints stayed untouched.

Land: 22.0× = 6.0× × 3.67× · **Pivot to NACF:** the same move on dock-to-stock cost: split a throughput gain into door-hours opened and unload rate before deciding which to fund.

Do NOT say: that the 56/44 split was measured; any customer-growth multiple other than 9.7×; any dollar from the split as record.

B2 · "Describe a time when you refused to compromise your standards around quality/customer service, etc. Who was your customer? What was the result?" AIQB: Highest Standards Q1 **Insist on the Highest Standards** FACET: DEFINITIONS AND DENOMINATORS

Open (first two sentences): "Every owner wanted their metric on the page, and I froze seven and parked the rest. A number that changes definition cannot steer a rollout."

90-second STAR. S A weekly review drifts: metrics get added, definitions bend, the page stops meaning anything. **T** Keep the review decision-grade for a VP who would steer funding off it. **A** I wrote seven definitions, got each input owner to sign the one they would be red against, fixed the denominator at 15-day active, offered a parking lot for new metrics and held the line after sign-off. **R** Every red arrived with an owner and a dated fix; the same seven definitions later moved into code with no drift.

Land: seven metrics, 15-day active · **Pivot to NACF:** freeze door-utilization and weeks-of-cover definitions before the quarter, signed by the node owner, so a red means the same thing in every building.

Do NOT say: "I invented the WBR" — it was copied from the LSA review, which was the point.

B3 · "Tell me about a time when you didn't have enough data to make the right decision. What did you do? What path did you take? Did the decision turn out to be the correct one?" AIQB: Are Right, A Lot Q1 **Earn Trust** FACET: DATA HONESTY

Open (first two sentences): "I had a week that printed ninety-nine point four percent and I threw it out. It rested on three touches, so I printed a data miss in its place."

90-second STAR. S The program was being doubted, and a flattering week landed. **T** Protect leadership's trust in the number over the next month, not the next meeting. **A** I computed the interval: 3 of 3 gives a 95% Wilson interval of 0.44 to 1.00 — wider than the ±5% band. I told the VP it was a data miss, not a result. **R** The number never had to be walked back, and the critic who started this later steered by the review.

Land: N = 3 → interval 44%–100% · **Pivot to NACF:** a unit-fill or WOC reading built on a handful of trailers or SKUs gets marked insufficient volume, not headlined.

Do NOT say: what the "real" number was — I do not have one and will not invent it.

B4 · "Tell me about a situation that required you to dig deep to get to the root cause. How did you know you were focusing on the right things? What was the outcome? Would you have done anything differently?"

AIQB: Dive Deep Q2 | Are Right, A Lot | FACET: ROOT CAUSE ON MEASUREMENT

Open (first two sentences): "The weekly automation rate fell from forty percent on the seventeenth of January to twenty-one point nine on the thirty-first — minus forty-five, deep red. Before the meeting I decomposed it, and it was a carrier format change, not the operators."

90-second STAR. **S** A red week landed on a desk that could have been blamed. **T** Find the cause before anyone defended or accused. **A** The standard work: source, definition, operator, in that order. The source had changed format; I assigned the owner a dated fix and checked the same number the next Monday. **R** The red arrived with an owner, the operators were not blamed, and the order of questions became standard work.

Land: (21.9 − 40.0)/40.0 = −45% — printed weekly values 17 Jan → 31 Jan 2022 (record) · **Pivot to NACF:** a sudden UPH or weeks-of-cover swing gets the same three questions — source, definition, operator — before an ops root cause is declared.

Do NOT say: the carrier name; that operators had slipped.

SAME STORY, THREE ANGLES — THREE CARDS, THREE OPENERS, THREE METRICS, THREE LPS

Data / analytical angle — Dive Deep

Opener: "Cost-to-serve fell 22× and I can tell you which lever did it — and why the answer depends on the order you ask."

Headline metric: 22.0× = 6.0× coverage × 3.67× touch efficiency; fair split 56% / 44% (modeled)

- Grain: container-week; join ticket ↔ container; 15-day active base.
- Identity: 6.0 × 3.67 = 22.0.
- Order test: $0.55/$0.08 coverage-first vs $0.48/$0.15 touches-first.
- Say "modeled" once, early; the record is the endpoints.

Conflict / influence / backbone angle — Insist on the Highest Standards

Opener: "The owners wanted their metric on the page. I held seven and gave them a parking lot — and a signature line."

Headline metric: seven frozen metrics, each signed by the owner who would be red against it

- The objection: more end-to-end input metrics, now.
- The answer: stability over coverage; a changing definition cannot steer a rollout.
- The mechanism: sign-off, freeze, parking lot — no argument by seniority.
- The proof: the same definitions moved into code with no drift.

Honest failure-and-learning angle — Ownership

Opener: "I started the review after the critique, not at kickoff — and for months I was its single point of failure."

Headline metric: by hand for months, about four hours a week at its worst; no longer a single point of failure once the pipeline matched within 1%

- What I would do differently: instrument at kickoff, not after the program fell from #3 to #14 of 16.
- What I would add now: a written sample floor (~139 active containers for ±5 points at 90%) instead of a judgment call on each small week.
- What fixed it: definitions in code (S16-A), not heroics.
- No dollar claimed for this angle.

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS

"How do you know the drop was your review and not the automation teams — or seasonality?"

Numeric answer. I do not claim the review built the automation; nine teams did (coverage 40% → 90%). The review's claim is narrower: it made boarding follow coverage — 9.7× the customers, zero rollbacks, both targets two months early. Cost-to-serve is a per-container ratio, so seasonal volume does not move it; a mix shift could, and I would check that by lane.

Say exactly: "I don't claim the review made the automation — the teams built that. The review's claim is narrower and checkable: it made boarding follow coverage, and the record shows zero rollbacks at 9.7 times the customers."

"Your decomposition rests on an assumption. What number would change your mind?"

Numeric answer. The endpoints do not depend on it; only the split does. Depending on attribution order coverage's share runs $0.15 to $0.55 of the $0.63 saving — 24% to 87% — so no single split is a measurement. Ticket-grain data showing touches on automated containers would move me to a two-factor model with an interaction term.

Say exactly: "The endpoints are record; only the split is modeled — and the split runs from twenty-four to eighty-seven percent depending on order, so I report the average and call it a convention."

"Three touches — why not just report it with a caveat?"

Numeric answer. The 95% interval was 0.44 to 1.00 — 0.56 wide — against a 0.10-wide red/green band, 5.6 times wider than the threshold. A caveat does not fix a reading the threshold cannot interpret. To read a rate to ±5 points at 90% I need about 139 active containers.

Say exactly: "A number whose interval is wider than the band you read it against isn't a reading. At three touches the interval was forty-four to a hundred; to read ninety percent within five points you need about a hundred and forty."

S11-B — Flexport — Launch readiness as standard work: four test gates, a 100-container hop-by-hop ledger and six graduation criteria — and the pilot that launched in December 2021, later than the first testing plan NEW

LPs this story can serve here: Insist on the Highest Standards (primary) · Customer Obsession · Dive Deep · Learn and Be Curious (the honest miss)
Process family: Deliver — launch readiness, test strategy and staged rollout; entry / exit criteria and go / no-go governance

LEADERSHIP PRINCIPLES THIS STORY CARRIES — ONE-LINE PROOF SENTENCE EACH

Insist on the Highest Standards Business UAT did not open until 80% of shipments showed minor-to-no issues, and no wave graduated until six published criteria passed — the gate was data quality, not the calendar.

Customer Obsession Shadow accounts ran two real Crux clients' live data beside the old product, and every new client supplied at least 50 containers of its own freight to calibrate on before onboarding.

Dive Deep The 100-container ledger traced real containers hop by hop; of 59 failing rows, 41 (69.5%) first broke at route creation or the milestone on screen — two hops, not seven.

Learn and Be Curious My test-effort estimates were optimistic and monitoring arrived late, so the pilot launched later than the first testing plan and bugs took hours to localize across six-plus layers — the lesson is to size testing on hop count and instrument first.

Honesty label. One of two technical program managers on the program (the record also names a co-TPM and a DRI). I owned the gate definitions, the readiness read-out and the go/no-go inputs; the 100-container log was run day to day by the QA team named in the testing approach, the hop-by-hop design is credited in the secondary loop packet to a test lead, and business users ran UAT. My own account (Apple v11 A5) is that I ran decision week as a two-gate go/no-go with criteria published beforehand, made the 100-container run the UAT spine with a Jira ID on every missed row, and set the UAT entrance criteria as exposure gates; I say "I defined the gates and ran the read-out", not "I ran the test". The ledger numbers below are *my recount of the 100-container working log* — a partial log where blank means not recorded.
Timing, doc against doc: the testing-approach document planned an early-November pilot; the program's year-end summary shows launch in December 2021 with delays among its misses; the pilot roll-out schedule has Wave 1 in Q4 2021, and my own workbook calls go-live "on schedule". I therefore say "later than the first testing plan", never "on time" and never a specific number of weeks late.

WHAT THE RECORD SAYS ABOUT READINESS (FROM THE PROGRAM DOCUMENTS; RECORD-FROM-DOCS)

Four test gates. A "100 container test" (random container and MBL numbers traced and logged, bugs in Jira, daily stand-ups); bug bashes every other week with job-story ranges assigned per person; shadow client accounts (client data uploaded to the legacy product fed into dedicated demo accounts, starting with two named Crux clients); and UAT with semi-weekly syncs, dependent on data quality first — 80% of shipments with minor-to-no issues. RECORD-FROM-DOCS

Go / no-go and waves. Two go/no-go meetings (business and tech) read: stable production, first-client data quality 80%+, no show-stoppers. Waves then graduated on six criteria — verification SLA 90% (max 48 h in "Verification in progress"), data quality 90%+ at least as accurate as the legacy product, milestone estimates 80%+, stable production, at least 100 containers plus key features used, and CSAT on par with the consignee average — with at least 50 containers of a new client's own data to calibrate on first, a free pilot and light-weight onboarding. RECORD-FROM-DOCS

Where it landed. The Nov 2021 status read Yellow with both checkpoints passed, a performance test of 500 containers in 20 minutes at 99.6% connectivity accuracy, end-to-end 100% processed and 86% trackable on 11/18, job stories 98.4% complete. The year-end summary: launched in December 2021, nine teams and close to 100 people, three environments built — and the misses: delays, optimistic testing estimates, and monitoring implemented late (bugs took hours to localize across six-plus system layers). RECORD-FROM-DOCS

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. Flexport's shipment-visibility pilot was first planned for early November 2021 and launched in December. It ran on a new stack across nine teams and close to a hundred people, with data crossing six or more system layers before it reached a client's screen. **Task.** As one of the program's two TPMs, I owned the readiness gates: what had to be true before a client touched the product, and before each wave graduated. **Action.** We tested in four layers — a 100-container live test, biweekly bug bashes, shadow accounts that ran two real clients' data beside the old product, and business UAT that opened only when 80% of shipments showed minor-to-no issues. The 100-container ledger traced real containers hop by hop — created, subscribed, data back, route, milestone, exception, webhook — and its Pareto was blunt: of 59 failing rows, 41 first failed at route creation or the milestone on screen. Graduation was six published criteria, with at least 50 containers of the client's own freight to calibrate on first. **Result.** Primary metric: the gate held — a 500-container load test in 20 minutes at 99.6% connectivity, both go/no-go checkpoints passed, no wave rolled back. The honest part: my test-effort estimates were optimistic and monitoring arrived late, so the pilot launched later than first planned and bugs took hours to localize; I now size testing on hop count and put the monitors in first.

SAFE-SAY — TWO SENTENCES TO SAY EXACTLY

Most attackable number. “Of fifty-nine failing rows in the hundred-container log, forty-one — about seventy percent — first broke at two hops, route creation and the milestone on screen; that is my recount of a working log, so it tells you where to look, not a defect rate.”

“What's your source for that?” “The pre-launch evidence is in the program's own status documents — five hundred containers in twenty minutes at ninety-nine point six, the dry run a hundred percent processed and eighty-six tracked — and the hop recount is mine from the log file.”

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — The visibility pilot had to go live to Crux-grade clients on a brand-new stack: nine teams, close to 100 people, three environments, data traveling through six-plus system layers before it reached the Client App. The testing plan targeted an early-November pilot; the status record shows end of November and the year-end summary shows December 2021 (the roll-out schedule keeps Wave 1 inside Q4, and my own workbook records go-live on schedule — the documents disagree on whether December was late). The program's own retrospective calls the testing estimates "overly optimistic for the complexity of the product" and names monitoring as implemented too late.

T — Define "ready": the gates before a client touches the product, the criteria to graduate each wave, and the evidence the go/no-go checkpoints would read — so rollout followed data quality, not the calendar.

Baselines on the table: First testing plan early Nov 2021 → launched Dec 2021 (docs disagree whether late) · 9 teams / ~100 people · 6+ system layers · 3 environments · 4 test gates · 6 graduation criteria · ≥50 containers per new client to calibrate · UAT entry gate 80% minor-to-no issues · ledger: 474 containers listed, 142 marked tested, 105 with hop results.

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery** — defined "working" per container as seven checks (created, subscribed, data back, route, milestone, exception, webhook); read the product standards (coverage 90%+, accuracy 95%, timeliness 90%) and what each go/no-go would read. *Exit bar:* seven checks and four gates named; the questions the go/no-go answers written down.
- **Plan & Design** — four test gates; the UAT entry gate at 80% minor-to-no issues; six graduation criteria published before wave 1; at least 50 containers of each new client's own freight before onboarding; free pilot, light-weight onboarding, monthly go/no-go. *Exit bar:* criteria published to Sales and the business before wave 1.
- **Build & Test** — the 100-container log in daily stand-ups; bug bashes by job-story range; shadow accounts on real Crux data; production connectivity monitors for the hops; a trace ID and per-hop ratios proposed after the slow bug

hunts — the logs showed no unique ID tying events from downstream to the screen, so finding the source system took 2–4 hours per blocker; the recommendation cut blocker-bug time-to-resolve by about half (3PL ingestion one-pager). *Exit bar:* 500 containers / 20 minutes / 99.6%; end-to-end 100% processed, 86% trackable on 11/18.

- **Cutover & Go-Live** — two go/no-go checkpoints (business, tech) on stable production, first-client data quality 80%+ and no show-stoppers; wave 1 started in December with two hand-carried customers (the schedule and my workbook agree on those two; two other accounts ran as shadow UAT accounts, and the Nov 19 status note's "first pilot client" is the earlier plan — I say "the first two hand-carried customers", no names, unless asked). *Exit bar:* both checkpoints passed; wave 1 live.
- **Hypercare / Close** — feedback session about a week after kickoff; a 50-container calibration sample from each wave-2 client before onboarding; monthly go/no-go on the six criteria; production data-quality testing on the same per-hop ratios. *Exit bar:* wave 2 opened on wave 1's graduation read; zero rollbacks.

Influence and ownership. Mine: the definition of ready, the gate and criteria design, the go/no-go inputs and the pre-production measurement design (S11). The QA team ran the log, a test lead designed the hop columns, the engineering teams instrumented their hops and fixed what the log found, business users ran UAT, and product and engineering leadership took the go/no-go.

> **Designed the process; others own it now.** The gates and criteria are published artifacts, the ledger columns are the standard checklist, and the per-hop ratios became standing monitors — the launch reads off documents, not off me.
> **Trade-off put to leadership.** Launch date versus data quality: I recommended the data-quality gate and accepted the later date it implied.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY (RECORD VS MODELED LABELED)

- **$** — no record dollar for the testing layer. The ~$1.5M pre-production estimate is S11's separate user anchor and is never merged. An illustrative escape cost at the record $0.18 per touch is under $1K a year — the real cost of an escaped defect is the rollback and the first impression, which is what the gates bought.
- **#** — four gates; six graduation criteria; 500 containers in 20 minutes at 99.6%; end-to-end 11/18 100% processed, 86% trackable; job stories 98.4% complete; both go/no-go checkpoints passed (record-from-docs).
- **%** — UAT entry gate 80% minor-to-no issues; graduation bars 90% data quality, 80% milestone estimates, 90% verification SLA; ledger first-failure Pareto 69.5% in two hops (my read of the log).
- **Time** — pilot launched December 2021, later than the early-November testing plan (record-from-docs; the docs disagree whether it was late); bug localization took hours across six-plus layers (record); about half that after the trace ID (3PL ingestion one-pager: blocker-bug time-to-resolve −50%).
- **Customer** — shadow accounts on two real clients' data; ≥50 containers of each new client's freight to calibrate on; CSAT par with the consignee average inside the graduation gate (record-from-docs).
- **Quality** — zero rollbacks through the waves (record, S11 canon); every ledger miss ticketed to the owning team.

L6 LEVEL EVIDENCE — this story against the Amazon L6 functional rubric; every line is this story's record or labeled model

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	"Ready" was undefined for a new-stack product. I defined the seven checks, the four gates and the graduation criteria, and what each go/no-go would read.
Scope & influence	Nine teams and ~100 people across three environments; I held the gates without owning any team — the criteria were published, the checkpoints were business and tech leadership's.
Execution trade-off + mechanism others now own	Date versus data quality: the UAT gate cost schedule and saved the first impression. Mechanism others own: the published criteria, the per-hop ratios as monitors.
Impact (long-term)	A launch with no rollbacks and a repeatable wave machine from 2 → 4 → 20+ clients; the monitors outlived the launch.
Process improvement (standard work institutionalized)	Standard work for launch: entry gate, calibration volume per client, six graduation criteria, monthly go/no-go, per-hop ratios.
Complexity & consensus	Nine teams with separate backlogs, an acquired product's clients in the middle of the rollout, and a date everyone wanted; the gates made the trade explicit.
Root cause at scale	A Pareto of first-failing hop located the defects (route, milestone) instead of counting symptoms; the missing seam — a trace across hops — was the root cause of slow debugging.

FIVE FACETS AT A GLANCE — the labeled structure the probing section below follows

1 · Data analysis	The 100-container ledger as a hop-by-hop Pareto: 142 tested, 105 with results, 59 failing, first failure at route (23) or milestone (18); partial-log caveat.
2 · Solution design	Hop ledger at the base of a four-gate pyramid; UAT gated on data quality; waves behind six criteria; calibration volume per client; light-weight onboarding.
3 · Math & data logic	Detection power: 1 − 0.95^50 = 92.3%; 1 − 0.97^100 = 95.2%; 1 − 0.99^300 = 95.1%; rule of three 3/100; load 500 / 20 = 25 per minute.
4 · Implementation	Four gates with owners and cadence; two go/no-go checkpoints; waves; monitors; three environments; risks and the late-monitoring lesson.
5 · Probe questions	Seven numeric probes plus three trap drills: zero-rollback luck, the partial log, the later launch and its leading indicator.

PROBING — FIVE FACETS, THEN THE FULL DRILL

Facet 1 — Data analysis (what data, grain, joins, cuts, what it revealed)

What the ledger is. One row per container or MBL; one column per hop — created, subscribed in SV, data back, route created, milestone shown, exception shown, webhook created — plus an overall Success flag, a date and the bug IDs RECORD-FROM-DOCS. Population as I read it: 474 containers listed, 142 marked tested, 105 with at least one hop result, 53 with an overall verdict (19 Yes, 34 No) — a partial working log; blank means not recorded, and twelve numbered issues sit in the bug column.

The right Pareto is first-failing hop, not No-counts per column. Downstream hops cascade — a failed route makes the milestone fail — so counting every "No" double-counts one fault. Of the 105 rows with results, 59 had at least one "No"; each was assigned to the first hop in order that failed:

FIRST FAILING HOP	ROWS	SHARE OF 59	CUMULATIVE
Route created?	23	39.0%	39.0%
Milestone shown in UI?	18	30.5%	69.5%
Data back from the legacy source	7	11.9%	81.4%
Exception shown in UI?	6	10.2%	91.5%

FIRST FAILING HOP	ROWS	SHARE OF 59	CUMULATIVE
Shipment created?	5	8.5%	100.0%

What it revealed. Two hops — route creation and the milestone on screen — hold 41 of 59 first failures (69.5%); the ingestion hops (created, data back) hold 12 (20.3%). Only 3 of the 105 rows passed all seven hops. So the defects were downstream of ingestion, which is where the bug bashes and the owning teams went first. Caveats I would say out loud: this is a working log, not a random sample, and I would re-run a fresh random 100 and log all seven hops to turn the Pareto into a defect-rate estimate. The Pareto is my recount of the 100-Container Debugging Session log, not a number printed in any document.

Facet 2 — Solution design (options considered, chosen design, why)

DESIGN QUESTION	OPTIONS WEIGHED	CHOSEN	WHY
Test structure	End-to-end pass counts only · a pyramid with a hop-by-hop ledger at the base	Pyramid + hop ledger	End-to-end says that it broke, not where; the hop column routes the ticket to the right team the same day (the seven checks and the Jira ID on every missed row are mine per my workbook; credit the QA team for running the log)
UAT entry	Open on the calendar (mid-October) · open on a data-quality gate (80% minor-to-no issues)	Quality gate	Business testers should validate the product, not rediscover known bugs (record-from-docs).
Pilot entry	Board the pool at once · waves 2 → 4 of 7 → 20+ behind six criteria	Waves	A free pilot spends engineering, data and ops before revenue; the gate must fire before the next wave (record-from-docs; S11).
Calibration	Onboard, then measure · at least 50 containers of the client's own freight first	Calibrate first	The product holds data on the client's lanes by the time they onboard; 50 containers detect a 5% defect 92.3% of the time.
Onboarding weight	API integration and LOAs from day one · light-weight until about wave 2	Light-weight	Limits the client's investment if the product misses expectations (record-from-docs).
Monitoring	Debug as you go · instrument the hops first (trace ID, per-hop ratios, connectivity monitors)	Instrument first — I did it late	The program's own retrospective: bugs took hours to localize at six-plus layers; the lesson is the story's honest half.

Facet 3 — Math & data logic (four tables: Before · Fix substituted · After · Dollars)

Table 1 — Before: the problem in numbers

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Ledger population	`142 marked tested / 474 listed = 30.0%; 105 with hop results / 142 = 73.9%`	record-from-docs; my count of the working log (blank = not recorded)	142 of 474; 105 with results
2	Overall verdicts	`19 Yes / 53 verdicts = 35.8%`	record-from-docs; partial log	35.8% passing at the time logged
3	Rows with a failing hop	`59 / 105 = 56.2%; all seven hops Yes: 3 / 105 = 2.9%`	record-from-docs; my count	59 failing; 3 clean
4	Localization cost	`hours per blocker across 6+ system layers; 2–4 h in the loop-packet telling`	record-from-docs (hours); secondary source (2–4 h)	2–4 h per blocker

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
5	Plan versus actual	`testing-approach plan: early November 2021; launch: December 2021 (year-end summary)`	record-from-docs, doc against doc (month-level resolution)	later than the first testing plan

Table 2 — The fix: gates and detection power, values substituted

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Calibration sample	`P(detect ≥ 1 defect) = 1 − 0.95^50 = 92.3% at a 5% defect rate`	record sample size (≥50 containers); defect rate illustrative	92.3%
2	Launch gate sample	`1 − 0.97^100 = 95.2% at a 3% defect rate`	record sample size (100 containers); defect rate illustrative	95.2%
3	If the 100 all pass	`upper bound = 1 − 0.05^(1/100) = 2.95% (rule of three: 3/100 = 3.0%)`	arithmetic	defect rate below ≈3% at 95%
4	Pre-production production test	`1 − 0.99^300 = 95.1% at 1% defects; 1 − 0.98^300 = 99.8% at 2%`	record sample size (300 containers, S11); defect rates illustrative	95.1% / 99.8%
5	Entry and graduation bars	`UAT opens at ≥80% minor-to-no issues; pilot entry at first-client data quality ≥80%; graduation at ≥90% data quality, ≥80% milestone estimates, 90% verification SLA`	record-from-docs thresholds	staged bar: enter safe, graduate proven

Table 3 — After: the metric, before → after

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Load proof	`500 containers / 20 min = 25 per minute; 99.6% × 500 = 498 connected`	record-from-docs (Nov 2021 status)	25 per minute; 498 of 500
2	End-to-end on 11/18	`100% processed; 86% trackable → 100 − 86 = 14% not trackable`	record-from-docs	14% untrackable that day
3	Job stories	`98.4% complete → 100 − 98.4 = 1.6% outstanding`	record-from-docs	1.6% outstanding
4	Go / no-go	`2 of 2 checkpoints passed (business, tech); criteria: stable production, first-client data quality 80%+, no show-stoppers`	record-from-docs	launch cleared
5	Scale outcome	`68 / 7 = 9.7×; zero rollbacks`	record (S11 canon)	9.7×

Table 4 — The dollars, every multiplication shown

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Containers per year	`32,000 shipments × 2.5 = 80,000`	illustrative containers per shipment (S11)	80,000
2	Escaped defects at a 5% rate	`80,000 × 0.05 = 4,000 containers`	illustrative defect rate	4,000
3	Direct touch cost of the escapes	`4,000 × $0.18 = $720 per year`	record $0.18 per interaction; one touch each (illustrative)	$720 — tiny: the cost is the rollback, not the touch

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
4	Localization labor (illustrative)	`5 blockers/wk × (3 h − 1.5 h) = 7.5 h/wk; 7.5 × 52 × $145 = $56,550`	illustrative: 5 blockers/wk is my example, not a source figure; 2–4 h per blocker and the ~50% cut are record-from-docs; $145/h from the S16-A model	≈$57K/yr — priced, not claimed; say the hours, not this dollar
5	Pre-production measurement path	`n = 300 → ±1.6% at 95%; rollout proof 1.5 vs 6 months`	user anchor (GFiber v8 only) — separate (S11), prefer the documents' 500 containers / 20 min / 99.6%	~$1.5M, never merged

No dollar in this story is a claimed saving. The two priced rows are illustrations built on the record $0.18 per touch and on a labeled localization model; the ~$1.5M stays with S11.

Facet 4 — Implementation (phases, owners, rollout, cutover, controls, risks)

GATE	ENTRY → EXIT	CADENCE AND OWNER	CONTROL
100-container test	random container / MBL numbers → every hop logged; bugs to Jira	ongoing; QA team; daily stand-up	every miss ticketed to the owning team; re-test the same container
Bug bash	job-story ranges assigned per person → issues logged	every other week; whole team	UI, data and performance in one pass
Shadow accounts	legacy-client uploads fed into dedicated demo accounts → side-by-side read	ongoing; two named clients first	real client data exposes defects synthetic data hides
UAT	opens at ≥80% minor-to-no issues → semi-weekly syncs (daily in November)	business users	quality gate, not calendar
Go / no-go ×2	stable production · first-client DQ 80%+ · no show-stoppers	business and tech leadership	evidence pack prepared in advance
Waves	6 criteria → next wave; ≥50 containers calibration; monthly go/no-go	program + business	hold in public if a criterion misses

Risks and mitigations. Environment outages (three environments; a "path to green" process to protect UAT availability); late monitoring (per-hop ratios and connectivity monitors — built later than they should have been); optimistic estimates (the lesson). **Lean / Kaizen mapping.** The ledger is genchi genbutsu — trace the real unit; the UAT gate is jidoka — stop the line on data quality; the criteria are standard work; the monthly go/no-go is PDCA at wave grain; defects found at the bottom cost a ticket, found by a client they cost trust.

Facet 5 — Probe questions (hardest follow-ups, numeric answers)

> **Was the pilot late, and whose miss was it?**
>
> The first testing plan said early November and it launched in December; the program's retrospective lists delays, optimistic testing estimates and late monitoring, and I was one of its two TPMs, so I own my share of the estimate. I won't say how much was mine against the co-TPM's — I wasn't the only estimator. I now size test effort on hop count and put the monitors in before the debugging starts.

> **What does your ledger actually prove?**
>
> Where to look first, not a defect rate. It is a partial working log: 142 marked tested, 105 with results, 59 failing. By first-failing hop, route (23) and milestone (18) hold 41 of 59 — 69.5% — and only 3 of 105 passed all seven hops. To estimate a rate I would re-run a fresh random 100 and log every hop.

Why is entry at 80% but graduation at 90%?

The bars answer different questions. Entry (first-client data quality 80%+, no show-stoppers) says "safe enough for a calibrated client"; graduation (90%+ at least as accurate as the legacy product, 80%+ milestone estimates, 90% SLA) says "proven enough for the next wave" (record-from-docs).

Why at least 50 containers to calibrate?

Because 50 detects a 5% defect 92.3% of the time (1 − 0.95^50), and 100 detects it 99.4% (1 − 0.95^100). Fifty is the cheapest sample that gives the data team a verified baseline on the client's own lanes before onboarding.

How did you decide UAT could open?

On the 80% minor-to-no-issues gate: business testers are further from product development, so opening earlier would have had them rediscovering known bugs. The gate was data quality, not the calendar — which is also why it moved the date.

Is 500 containers in 20 minutes a lot?

25 containers a minute; 99.6% connected is 498 of 500. At the S11 illustrative 80,000 containers a year (≈219 a day) one 20-minute run is ≈2.3 days of average volume — headroom, not proof of peak behavior, and I said so.

What would you change about the testing plan?

Monitors before debugging, effort sized on hop count, the trace ID agreed in design rather than after the first slow bug hunts, and the three environments treated as the critical path — the record's own list of what went wrong.

BUSINESS IMPACT MODEL — KPI TREE

```
Launch readiness: no client touches the product until the evidence says it is ready
+- GATE 1  100-container live test: 7 hop checks per container, every miss a ticket
+- GATE 2  bug bashes every other week: job-story ranges per person
+- GATE 3  shadow accounts: real legacy-client data beside the old product
+- GATE 4  UAT opens at >=80% of shipments minor-to-no issues
+- GO / NO-GO x2 (business + tech): stable prod, first-client DQ >=80%, no show-stoppers
+- WAVES   2 -> 4 of 7 -> 20+: six criteria; >=50 containers of calibration per new client
+- RESULT  500 containers / 20 min / 99.6%; zero rollbacks; customers 7 -> 68 (9.7x)
(loop)  hop ledger -> first failing hop -> right team same day -> fewer escapes -> shorter next cycle
(miss)  optimistic estimate + late monitors -> pilot: first plan early Nov, launched Dec; bugs took hours
to localize
```

SOLUTION FLOW

```
random container/MBL -> trace 7 hops -> log row -> first failing hop?
   -> Jira ticket to the owning team -> daily stand-up -> fix -> re-test the same container
shadow account (real client data) -> side-by-side with the old product -> defects
UAT opens at >=80% minor-to-no issues -> semi-weekly syncs
GO / NO-GO (business + tech) -> wave 1 -> six criteria -> monthly go/no-go
   -> wave 2 (>=50 containers calibration first) -> wave 3 -> full roll-out
```

SENSITIVITY — LOW / BASE / HIGH

TRUE DEFECT RATE (ILLUSTRATIVE)	FORMULA	N = 50	N = 100	N = 300
1%	1 − 0.99^50	39.5%	63.4%	95.1%
3%	1 − 0.97^n	78.2%	95.2%	99.99%
5%	1 − 0.95^n	92.3%	99.4%	≈100%

Probability that a sample of n containers contains at least one defective container. The record sample sizes are 50 (calibration), 100 (launch gate) and 300 (pre-production); defect rates are illustrative.

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

Honestly, the testing layer has no record dollar and I don't invent one. What it has is a gate that held: a hundred-container live test traced hop by hop, shadow accounts on real client data, UAT that stayed closed until eighty percent of shipments showed minor-to-no issues, and six published criteria for each wave — with a fifty-container calibration first, which detects a five-percent defect more than nine times in ten. The load proof was five hundred containers in twenty minutes at ninety-nine point six percent, both go/no-go checkpoints passed, and no wave rolled back. The ledger told us where to look — forty-one of fifty-nine failing containers broke first at route or milestone — and it is a working log, so I use it to aim the fix, not to estimate a rate. The honest cost is the schedule: my testing estimate was optimistic and monitoring came late, so the pilot launched in December, later than the first testing plan. I would take that trade again, and I would instrument first.

IF CHALLENGED — THE FULL ANSWERS

"You had zero rollbacks — isn't that just luck with only three waves?"

Zero events in three waves proves little statistically — the 95% upper bound on a per-wave rollback rate is 1 − 0.05^(1/3) = 63%. The evidence is the gates' detection power (92.3% at 50 containers for a 5% defect, 95.2% at 100 for 3%) and that exposure was bounded: wave 1 was two clients, not the whole seven-client pool.

"Why trust a log with blanks?"

I don't use it as a sample. I use it to rank where to look: 59 failing rows, first failure at route or milestone in 41. To estimate a rate I would re-run a random 100 with every hop recorded.

"What did the later launch cost?"

The record does not price it and the pilot was free, so there was no revenue delay to claim. The cost was engineering capacity, client expectation and credibility — I do not put a number of weeks on it, because the documents disagree — which is why the lesson is about estimates and monitoring, not about the gate.

20-SECOND VERSION AND NACF BRIDGE

20-SECOND VERSION

At Flexport I defined "ready" for a visibility launch: four test gates — a hop-by-hop 100-container ledger, bug bashes, shadow accounts on real client data and UAT that opened only at 80% data quality — and six graduation criteria per wave. The gates held and nothing rolled back; the honest miss was optimistic test estimates and late monitoring, which put the launch in December, later than the first testing plan.

NACF BRIDGE — ONE SENTENCE

A new inbound node launches the same way: trace real units hop by hop (ASN → appointment → door → receive → putaway → available), publish the entry gate and a calibration volume per node before the first trailer, and put the monitors in before the first week of debugging — doors × hours × unload rate only means something once each hop is measured.

BEHAVIORAL PACK — FOUR QUESTIONS THIS STORY ANSWERS, EACH A SEPARATE 90-SECOND STAR FROM A DIFFERENT FACET

B1 · "Tell me about a time when you had to make a decision between standards and delivery. What tradeoffs did you have make? What was the outcome? Knowing what you know now, would you have done anything differently?" AIQB: Highest Standards Q4 **Insist on the Highest Standards** FACET: THE UAT GATE

Open (first two sentences): "We kept business UAT closed until eighty percent of shipments showed minor-to-no issues. Opening it on the calendar would have had business testers rediscovering bugs we already knew about."

90-second STAR. S A new-stack launch with a calendar everyone wanted. **T** Make "ready" a rule, not a feeling. **A** I helped define four gates and set UAT's entry at 80% minor-to-no issues, with graduation criteria for each wave published before wave 1; the first-client go/no-go read stable production, 80%+ data quality and no show-stoppers. **R** Both checkpoints passed and nothing rolled back — and the price was real: the pilot launched in December, later than the first testing plan.

Land: UAT entry 80%; six graduation criteria · **Pivot to NACF:** a new node does not take inbound until its entry gate is met — doors staffed, WMS receiving verified, first trailers traced — whatever the launch calendar says.

Do NOT say: that the later date was "worth it" without naming the cost; any dollar for the gate.

B2 · "Tell me about a time when you evaluated the customer experience of your product or service. What did you do? What was the result?" AIQB: Customer Obsession Q5 **Customer Obsession** FACET: SHADOW ACCOUNTS AND CALIBRATION

Open (first two sentences): "We ran two real clients' live data from the old product through the new one in demo accounts, side by side. And every new client gave us at least fifty containers of their own freight before they onboarded."

90-second STAR. S Synthetic tests were not going to show what a client's lanes and carriers actually do. **T** Find the defects on the client's own freight, before the client sees them. **A** Shadow accounts fed the legacy-product uploads of two named clients into dedicated demo accounts; wave-2 clients supplied a 50-container sample for calibration; the six criteria included CSAT on par with the consignee average. **R** Defects surfaced in our accounts, not theirs; the onboarding was light-weight because the product had calibrated on their freight.

Land: ≥50 containers → 92.3% chance to detect a 5% defect · **Pivot to NACF:** a node's first inbound sample — a trial volume per node — calibrates receiving and putaway before the node takes real peak volume.

Do NOT say: client names beyond what is confirmed; "customers loved it" — the record has no such claim.

B3 · "Tell me about a time when you were trying to understand a complex problem on your team and you had to dig into the details to figure it out. Who did you talk with or where did you have to look to find the most valuable information?" AIQB: Dive Deep Q1 **Dive Deep** FACET: THE HOP LEDGER

Open (first two sentences): "We traced real containers through seven hops and logged every one. When I counted by first failing hop instead of by column, forty-one of fifty-nine failures were at just two hops."

90-second STAR. S Six-plus system layers and a pile of defects, with every team seeing only its slice. **T** Locate the defects instead of counting symptoms. **A** I read the log by first-failing hop because downstream hops cascade: route (23), milestone (18), data back (7), exception (6), created (5). I took the top two to the owning teams first and kept the caveat — it is a working log, not a sample. **R** The fixes were aimed at route and milestone first; the log became the standing checklist.

Land: 41 of 59 first failures at two hops (69.5%) · **Pivot to NACF:** a receiving-defect Pareto by first failing step, not by total flags — so one dock-scheduling fault is not counted four times downstream.

Do NOT say: that the log estimates a defect rate; the share as precise.

B4 · "We all have things about ourselves we'd like to improve on at work. Give me an example of something that you've worked on to improve your overall work effectiveness. What resources did you identify to help you develop? What was the impact?" AIQB: Learn and Be Curious Q4 **Learn and Be Curious** FACET: THE HONEST MISS

Open (first two sentences): "The first testing plan said early November; the pilot launched in December. The program's own retrospective says our testing estimates were overly optimistic and monitoring came too late — and I was one of its two TPMs."

90-second STAR. **S** A launch across nine teams on a new stack. **T** Land a safe pilot; the estimate was part of the job. **A** I held the data-quality gate and accepted the later date rather than launch on the plan. The slow part was debugging: data crossed six-plus layers with little monitoring, and bugs took hours to localize. We added a trace across hops and per-hop ratios. **R** The pilot launched clean; the lesson is to size testing on hop count and instrument before debugging starts.

Land: first plan early November → launched December 2021 · **Pivot to NACF:** size a new-node launch plan on the number of hand-offs, and put the receiving monitors in before the first inbound wave.

Do NOT say: blaming other teams; "about a month" as a precise figure — the record is month-level.

SAME STORY, THREE ANGLES — THREE CARDS, THREE OPENERS, THREE METRICS, THREE LPS

Data / analytical angle **Dive Deep**

Opener: "Of fifty-nine failing containers, forty-one first broke at one of two hops — and only three of a hundred and five passed all seven."

Headline metric: 41 of 59 (69.5%) at route + milestone; 3 of 105 all-seven-clean

- Read by first-failing hop, not by column.
- Order: route 23, milestone 18, data back 7, exception 6, created 5.
- Caveat first: partial log, blank = not recorded.
- Next step: a fresh random 100 with every hop logged.

Conflict / influence / backbone angle **Ownership**

Opener: "Nine teams, none reporting to me, each with its own backlog — I had to get every one to instrument its own hop in the middle of a launch crunch."

Headline metric: nine teams aligned on one seam; time to localize cut about 50% (secondary source)

- The seam nobody owned: no unique ID from downstream events to the screen.
- The ask was framed in each team's own bug queue, not the program's need.
- The sell was arithmetic: a few hours per blocker, every team paying it.
- Source: the 3PL ingestion one-pager (TPM across 6 systems and 9 teams; no unique ID; 2–4 hours to find the source system per blocker; blocker-bug time-to-resolve cut about 50%).

Honest failure-and-learning angle **Learn and Be Curious**

Opener: "The first testing plan said early November and we launched in December, and the program's own retrospective says why: testing estimates were optimistic and monitoring was late."

Headline metric: first plan early November → launched December 2021; hours to localize a bug at six-plus layers

- What I would do differently: size testing on hop count; monitors before debugging.
- What the record calls a win, I read as a warning: the environment was built "through long hours" — optimistic estimates are paid for by people.
- What held: the gates — no wave rolled back.
- No dollar claimed.

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS

"With only three waves, how do you know your gates caused zero rollbacks — and not luck?"

Numeric answer. I don't, statistically: zero events in three waves gives a 95% upper bound of 1 − 0.05^(1/3) = 63% on a per-wave rollback rate. The case rests on detection power — 92.3% at 50 containers for a 5% defect, 95.2% at 100 for 3% — and on bounded exposure: wave 1 was two clients, not seven.

Say exactly: “Zero in three waves proves almost nothing on its own — the upper bound is sixty-three percent. What I can show is the gates' detection power and that wave one was two clients, not the whole pool.”

"Your ledger is a partial log. Why should I trust the Pareto?"

Numeric answer. Because I only claim what it supports: 105 rows had results, 59 had a failing hop, 41 of those first failed at route or milestone. Blank is not "pass," and a working log over-records failures, so the shares are indicative; the robust finding is that failures sat downstream of ingestion. I would re-run a random 100 with all seven hops logged.

Say exactly: “It's a working log, not a sample — blank means not recorded. I use it to decide where to look first, not to estimate a defect rate.”

"The pilot launched later than planned. What number would have told you earlier?"

Numeric answer. Hours to localize a blocker: the record says bugs took hours across six-plus layers (2–4 h in the secondary telling). A weekly chart of that figure against a ≤1 h target, from week one, would have shown the monitoring gap before the date did.

Say exactly: “The number I should have charted from week one was hours to localize a blocker — it was the leading indicator, and the date was the lagging one.”

S11-C — Flexport — Retiring an acquired product's book: a segment-by-segment RAPID decision for 79 Crux customers — 55 onto Shipment Visibility, 24 on rule-based exits, and three customers carrying 75% of the containers NEW

LPs this story can serve here: Customer Obsession (primary) · Success and Scale Bring Broad Responsibility · Earn Trust · Have Backbone, Disagree and Commit
Process family: Deliver — customer transition and product retirement; segmentation, decision rights (RAPID) and cut-over planning

LEADERSHIP PRINCIPLES THIS STORY CARRIES — ONE-LINE PROOF SENTENCE EACH

Customer Obsession Every one of the 79 customers got a destination by segment — transition, partner route, or API-or-cancel with dates — instead of an end-of-life email.

Success and Scale Bring Broad Responsibility Three truck brokers were 3.8% of customers and 75.0% of containers, so they got a per-customer partner route; 39 small accounts at ≈$770 a year each got the standard path.

Earn Trust The decision document kept the dissent on the page — cost of two systems, an unwritten parity list, "ejecting customers is never a good experience" — and cancellations ran on published dates.

Have Backbone; Disagree and Commit The decider committed the organization with the objections recorded, and each impacted party committed to perform — nobody smoothed the disagreement away.

Honesty label. This is a decision-document story, and the seat matters: the RAPID table names the Recommend, Agree, Perform, Input and Decide people, and the decider is an executive — *the decision was not mine*. My seat, from my own workbook (Apple v11 A4): I owned the mitigation of the decommission risk — I put it on the risk register as the top risk, rebuilt the comparison apples to apples, priced the 79-customer base per segment, and wrote the one-canonical-source rule; the transition document's owners built the per-customer paths with me, and the decision itself was the executive decider's. The segment table is the doc's; the footing, concentration arithmetic, break-even rule and parity matrix are my analysis. **Footing flag:** the doc's printed total row ($15,491 MRR / $185,892 ARR) equals the sum of only the six non-transition segments; all nine rows sum to $21,246 MRR / $254,952 ARR, and the appendix lists 77 names against 79 counted (37 SMB names vs 39) The number I say in the room is the printed one — 79 customers, $185,892 ARR, 294,581 containers (Apple A4 prints the same) — and I add that the printed total equals six of the nine rows. Overlap: the loop packet tells this as S10 for another interviewer.

WHAT THE RECORD SAYS (FROM THE PROGRAM DOCUMENTS; RECORD-FROM-DOCS)

The opportunity. Migrate Crux clients to Shipment Visibility by the end of 2022. GKA, Enterprise and SMB customers transition and are upsell opportunities; for Motor Carriers, Truck Brokers, Freight Forwarders, Customs Brokers, 3PL and SCM SaaS the choice was cancel now, or keep serving them on Crux while working out missing features, support and Data Services cost-to-serve. RECORD-FROM-DOCS

The decisions. Truck brokers and motor carriers: transition AV Logistics and Loadsmart to partners in Transmission (like ITS, already there); cancel the remaining motor carriers at wind-down. Freight forwarders, customs brokers, 3PL: no new investment — recommend the SV API (no extra dev), else cancel at wind-down. SCM SaaS: cancel both — dated August 1 and October 24, 2022; the customs broker was cancelled September 1, 2022. A named executive decides; two people build the per-segment transition plans and review them with the exec team. RECORD-FROM-DOCS

The dissent. One reviewer wanted the cost of maintaining two systems and the stalled "Crux Absorption" project brought into the decision; another asked what Crux costs to keep running, whether the missing-feature list is written down, and warned that ejecting customers is never a good experience and that cancellations should be timed to win the competitors' consignees; others argued to cut direct competitors and to keep only partners. The 2021 plan adds that about 75% of Crux revenue came from clients who are not trade clients, so Crux's front end could not be sunset until the VaaS portal was stood up. RECORD-FROM-DOCS

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. Flexport had acquired a visibility product, Crux, and the goal was to move its clients to Shipment Visibility by the end of 2022 — but 79 paying customers and about 295 thousand containers a year were on it, and not all of them fit. The easy versions were an end-of-life email or running two systems forever. **Task.** Produce a decision rule per customer type that a decider could commit the company to, with the dissent visible. **Action.** I segmented the 79 into nine types and read each on three questions: does Shipment Visibility serve them, are they a partner or a competitor, and does serving them need extra build. Then I checked concentration: three truck brokers were 4% of customers and 75% of containers, so they got a per-customer partner route; the 39 small accounts, about $770 a year each, got the standard path. The decision: 55 customers to Shipment Visibility, three brokers to partners in Transmission, forwarders and 3PLs to the SV API or cancel at wind-down, nine motor carriers cancel at wind-down, and three dated cancellations. The dissent — cost of two systems, an unwritten parity list — stayed on the page. **Result.** Primary metric: 79 of 79 customers with a destination and a date — 55 + 3 + 9 + 9 + 3 — and a table footed by container share, because the printed ARR total summed only six of nine rows.

SAFE-SAY — TWO SENTENCES TO SAY EXACTLY

Most attackable number. “The document prints seventy-nine customers, $185,892 of annual revenue and 294,581 containers; I add that the printed revenue total equals six of its nine segment rows, so I lead with containers.”

“What's your source for that?” “The base is the transition document's own table, which my workbook also quotes; the footing, the three-brokers concentration and the break-even are my arithmetic on that table, and I label them that way.”

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — Flexport's acquired visibility product, Crux, still billed 79 customers — 294,581 containers in 2021 — while Shipment Visibility was in pilot. The aim was to migrate Crux clients by the end of 2022, but the decision document itself says not all customers fit the new service and a plan was needed. Keeping both meant two systems, double maintenance and a prospect set comparing Flexport against itself; closing Crux carelessly meant stranding customers who used it as infrastructure — and the plan's own dependency was that non-trade clients could not use the Client App at all until the VaaS portal existed.

T — Own the segmentation analysis and the per-segment recommendation a decider could commit to — transition, partner route, API-or-cancel, or cancel, each with a date — with the cost of two systems and the parity gaps on the page, not behind it.

Baselines on the table: 79 customers · 294,581 containers (2021) · nine segments · doc-printed ARR total $185,892 (six non-transition rows) vs nine-row sum $254,952 · 12 customers flagged API · 6 flagged churned in the appendix · goal: migrate by end of 2022 · ~75% of Crux revenue from non-trade clients (2021 plan).

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery** — footed the customer table (count, containers, ARR, MRR) and read each segment's use, revenue and containers; separated partners from competitors; listed what the plan itself said Crux customers could not do on SV. *Exit bar:* segment table reconciled to the appendix names; the footing differences written down.
- **Plan & Design** — a three-axis rule — does SV serve them, partner or competitor, extra build needed — mapped to five decisions; concentration analysis (brokers vs the long tail); the parity matrix drafted; the open questions listed (keep-alive cost, written parity list). *Exit bar:* RAPID roles named: Recommend, Agree, Perform, Input, Decide.
- **Build & Test** — collected stakeholder input verbatim, including the dissent; ran per-customer conversations for the large accounts with the trucking group; drafted the per-segment transition plans. *Exit bar:* the decider can read every objection beside the recommendation.
- **Cutover & Go-Live** — the decider committed the organization; each impacted party committed to perform; the SV-bound segments entered through the pilot waves; competing SCM SaaS and the customs broker were cancelled on dates. *Exit bar:* dated actions on the page: August 1, September 1 and October 24, 2022.

- **Hypercare / Close** — API-or-cancel conversations for forwarders and 3PLs; partner conversations for the brokers; wind-down of the Crux front end as VaaS / API paths landed; churn flagged in the appendix tracked. *Exit bar:* every customer on a path with a date; Crux wound down by the end-2022 goal.

Influence and ownership. Mine (as I would tell it): the segmentation, the concentration read, the plan inputs and the parity questions. Not mine: the recommendation owners, the decider and the per-segment transition plans' authors named in the RAPID table; the trucking group owned the partner conversations. I influenced by putting the numbers and the dissent on one page.

> **Designed the process; others own it now.** The segment rules, the dated cancellations and the parity questions live in the decision document, not in my head; the transition plans have named performers. **Trade-off put to leadership.** Revenue surrendered (the six non-SV segments, $185,892 of printed ARR) against two systems, double maintenance and competing with ourselves — and a keep-alive cost the record never priced.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY (RECORD VS MODELED LABELED)

- **$** — the doc's printed $185,892 ARR is the revenue on the six non-SV segments (modeled footing — mine); the three SV-bound segments add $69,060, for $254,952 across all nine rows. No Crux keep-alive cost exists in the record, and I do not invent one — the break-even is $15,491 a month (modeled).
- **#** — 79 of 79 customers with a decision: 55 to SV, 3 to Transmission partners, 9 SV-API-or-cancel, 9 cancel at wind-down, 3 cancelled now on dates (record-from-docs; tally mine).
- **%** — brokers 3.8% of customers and 75.0% of containers; SV-bound segments 69.6% of customers, 13.3% of containers, 27.1% of ARR (my footing of the doc table).
- **Time** — target: migrate Crux clients by end of 2022; cancellations dated August 1, September 1 and October 24, 2022 (record-from-docs).
- **Customer** — each customer type has a stated destination; the largest accounts got partner conversations, not a template; six customers were already flagged churned in the appendix.
- **Quality** — two open questions flagged rather than hidden — keep-alive cost and a written feature-parity list; the doc's own footing differences caught and reconciled.

L6 LEVEL EVIDENCE — this story against the Amazon L6 functional rubric; every line is this story's record or labeled model

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	An acquired product, nine customer types and no stated rule for who fits. I built the rule (serve? partner or competitor? extra build?) and the concentration read from the data.
Scope & influence	Executives decided; product, trucking, data services and finance gave input; I influenced by putting numbers and dissent on one page — a recommendation to leaders, one to two levels up.
Execution trade-off + mechanism others now own	Revenue for simplicity, with the cost of keeping both unpriced in the record. Mechanism others own: the segment rules, the dated cancellations and the decision document.
Impact (long-term)	One visibility product to run, the acquired book moved or exited deliberately, the partner route for the largest accounts preserved.
Process improvement (standard work institutionalized)	A reusable product-retirement template: segment by use, find concentration, rule per segment, dated actions, dissent recorded, commitments confirmed.
Complexity & consensus	Real dissent (cost of two systems, parity, customer experience, competitor timing) resolved by a named decider with commitments from each impacted party.
Root cause at scale	The root question was "who is this product for" — the plan's non-trade clients could not use SV, which is why the rule is by segment, not by customer.

FIVE FACETS AT A GLANCE — the labeled structure the probing section below follows

1 · Data analysis	Nine-segment table; footing (printed total vs nine rows); concentration (3 brokers = 75.0% of containers); ARR per customer 60× spread; API and churn flags.
2 · Solution design	Cancel all vs keep all vs segmented rules; broker route options; parity matrix; decision rights via RAPID.
3 · Math & data logic	Tally 55 + 3 + 9 + 9 + 3 = 79; shares 69.6 / 13.3 / 27.1% vs 30.4 / 86.7 / 72.9%; break-even $185,892 / 12 = $15,491 a month.
4 · Implementation	Per-segment plan, dated cancellations, commitments confirmed, SV pilot waves for the 55, partner conversations for the three.
5 · Probe questions	Seven numeric probes plus three trap drills: which total, will the brokers accept, what number would flip the cancel decision.

PROBING — FIVE FACETS, THEN THE FULL DRILL

Facet 1 — Data analysis (what data, grain, joins, cuts, what it revealed)

What I read. The doc's segment table (customers, MRR, ARR, 2021 containers) and its appendix of names, with API and churn flags RECORD-FROM-DOCS. I added three columns the doc does not carry — ARR per customer, share of containers and the decision — and footed everything from the rows.

SEGMENT	CUSTOMERS	ARR (DOC)	CONTAINERS 2021	ARR / CUSTOMER	% OF CONTAINERS	DECISION (DOC)
GKA	2	$16,500	17,061	$8,250	5.8%	transition to SV
Enterprise	14	$22,560	17,983	$1,611	6.1%	transition to SV
SMB	39	$30,000	4,153	$769	1.4%	transition to SV
Motor Carrier	9	$17,760	12,359	$1,973	4.2%	cancel at wind-down
Truck Broker	3	$139,512	221,044	$46,504	75.0%	Transmission partner route (else cancel)
Freight Forwarder	5	$14,820	11,871	$2,964	4.0%	SV API, else cancel at wind-down
Customs Broker	1	$600	432	$600	0.1%	cancel now (dated)
3PL	4	$2,400	4,218	$600	1.4%	SV API, else cancel at wind-down
SCM SaaS	2	$10,800	5,460	$5,400	1.9%	cancel now (dated)

What it revealed. (1) *Footing:* customers foot to 79 and containers to 294,581, but the printed $185,892 ARR is only the six non-transition rows — the nine rows sum to $254,952, so I lead with container shares, which foot. (2) *Concentration:* three truck brokers are 3.8% of customers, 75.0% of containers and 54.7% of nine-row ARR. (3) *Spread:* ARR per customer runs from $769 (SMB) to $46,504 (truck broker) — 60.5×. (4) *The SV-bound 55 are a long tail:* 69.6% of customers but 13.3% of containers and 27.1% of ARR — light-weight onboarding fits; the brokers need per-customer work. (5) The 2021 plan's "~75% of Crux revenue is non-trade" sits within two points of my 72.9% for the six non-SV segments. (6) Flags: 12 customers carry an API flag (5 of them SV-bound) and 6 are flagged churned. I quote 79 customers as printed (Apple A4 prints 79 too); I do not quote a per-customer average beyond the SMB tail.

Facet 2 — Solution design (options considered, chosen design, why)

DESIGN QUESTION	OPTIONS WEIGHED	CHOSEN	WHY (RECORD UNLESS MARKED)
Whole book	Cancel everything not on SV now · keep every customer on Crux until parity · segmented rules	Segmented rules	Cancel-all strands the large partner-like accounts; keep-all leaves two systems running with no end date and misses the end-2022 goal.
Truck brokers and motor carriers	Standalone service · white-label / partner via Transmission · cancel	Partner route for brokers; cancel the nine motor carriers at wind-down	The 2021 strategy doc gives no standalone service for these types; ITS already uses Transmission.
Forwarders, customs, 3PL	Build something extra · SV API (no extra dev) · cancel	SV API, else cancel at wind-down	No new investment; they are not competitors in the doc's reading and some give intel on their customers.
SCM SaaS	Explore data partnerships · cancel now	Cancel now (dated)	They could undermine selling our own branded services; one went through legal review.
Decision rights	Consensus · RAPID with a named decider	RAPID	Recommend, Agree, Perform, Input, Decide named; each impacted party commits.

Parity matrix (drafted from the documents; gaps flagged, not guessed)

DIMENSION	CRUX TODAY	SHIPMENT VISIBILITY	GAP AND HANDLING
Who can use it	Any customer type — shippers, carriers, brokers, forwarders, 3PL, SaaS	Client App for trade clients; non-trade clients cannot use it until a VaaS portal exists (2021 plan)	Rule by segment; non-trade types go API, partner or cancel
How tracking is requested	Front-end manual search and API	Single input, CSV or API in the Client App	Manual search is not offered on the VaaS-portal plan — a documented gap
Data-quality bar	The incumbent benchmark	Graduation: at least as accurate as Crux ≥90% of the time	Built into the six graduation criteria
Human in the loop	not in the documents — say "I don't know how Crux handled exceptions" VERIFY-WITH-RAJESH · V3	Tickets to Data Services when auto-tracking fails	Unknown on the Crux side
Webhooks / API	12 customers flagged API	Public API and client webhooks	Decision: "SV API, no extra dev effort"
Price	MRR by segment, $50–$11,626	Free pilot ≈6 months, then the SV charge model	The price step is the thing to explain to the SV-bound 55
Feature-parity list	A reviewer asked: "written down somewhere?"	—	Not in the record — the document records the question, not an answer; I do not claim the list existed in writing

Facet 3 — Math & data logic (four tables: Before · Fix substituted · After · Dollars)

Table 1 — Before: the problem in numbers (footing the doc's own table)

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Customers	`2 + 14 + 39 + 9 + 3 + 5 + 1 + 4 + 2 = 79`	record-from-docs rows	79
2	Containers, 2021	`17,061 + 17,983 + 4,153 + 12,359 + 221,044 + 11,871 + 432 + 4,218 + 5,460 = 294,581`	record-from-docs rows	294,581
3	ARR, all nine rows	`16,500 + 22,560 + 30,000 + 17,760 + 139,512 + 14,820 + 600 + 2,400 + 10,800 = $254,952`	my footing of the doc rows	$254,952
4	The printed total row	`17,760 + 139,512 + 14,820 + 600 + 2,400 + 10,800 = $185,892; $254,952 − $185,892 = $69,060 = the three SV-bound rows`	my footing: the printed ARR is the six non-transition rows	$185,892 (six rows)
5	MRR cross-check	`$21,246 (nine rows) − $15,491 (printed) = $5,755; $5,755 × 12 = $69,060`	my footing	$5,755 MRR missing from the printed total

Table 2 — The fix: the rules, the tally and the concentration, values substituted

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Decision tally	`55 (SV) + 3 (Transmission partners) + 9 (API-or-cancel) + 9 (cancel at wind-down) + 3 (cancel now) = 79`	record-from-docs decisions; tally mine	79 of 79 with a destination
2	Broker concentration	`3 / 79 = 3.8% of customers; 221,044 / 294,581 = 75.0% of containers; 139,512 / 254,952 = 54.7% of ARR`	my footing	3.8% → 75.0% / 54.7%
3	ARR per customer spread	`$30,000 / 39 = $769 (SMB); $139,512 / 3 = $46,504 (brokers); 46,504 / 769 = 60.5×`	my footing	60.5×
4	SV-bound segments	`55 / 79 = 69.6% of customers; 39,197 / 294,581 = 13.3% of containers; 69,060 / 254,952 = 27.1% of ARR`	my footing (39,197 = 17,061 + 17,983 + 4,153)	69.6% / 13.3% / 27.1%
5	Exit and re-route segments	`24 / 79 = 30.4%; 255,384 / 294,581 = 86.7% of containers; 185,892 / 254,952 = 72.9% of ARR`	my footing (255,384 = 294,581 − 39,197)	30.4% / 86.7% / 72.9%

Table 3 — After: where each customer goes (customers · containers)

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	To Shipment Visibility	`GKA 2 + Enterprise 14 + SMB 39 = 55 customers; 39,197 containers`	record-from-docs decision	55 · 39,197
2	To partners in Transmission	`truck brokers: 3 customers; 221,044 containers (else cancel at wind-down)`	record-from-docs decision	3 · 221,044
3	SV API, else cancel at wind-down	`forwarders 5 + 3PL 4 = 9 customers; 11,871 + 4,218 = 16,089 containers`	record-from-docs decision	9 · 16,089
4	Cancel at wind-down	`motor carriers: 9 customers; 12,359 containers`	record-from-docs decision	9 · 12,359
5	Cancel now (dated)	`customs 1 + SCM SaaS 2 = 3 customers; 432 + 5,460 = 5,892 containers`	record-from-docs decision	3 · 5,892
6	Footing check	`39,197 + 221,044 + 16,089 + 12,359 + 5,892 = 294,581`	arithmetic	every container accounted for

Table 4 — The dollars, every addition shown (ARR; pilot is free, so none of it is "saved")

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	ARR on the SV-bound segments	`$16,500 + $22,560 + $30,000 = $69,060`	my footing of the doc rows; flows into the charge model after the pilot	$69,060
2	ARR on the exit and re-route segments	`$17,760 + $139,512 + $14,820 + $600 + $2,400 + $10,800 = $185,892`	the doc's printed total, footed	$185,892
3	Of which hard-cancel	`$17,760 (motor carriers) + $600 (customs) + $10,800 (SCM SaaS) = $29,160`	my footing	$29,160
4	Of which conditional on SV-API uptake	`$14,820 (forwarders) + $2,400 (3PL) = $17,220`	my footing	$17,220
5	Of which the partner route	`$139,512 / $185,892 = 75.1% of the exit ARR; 29,160 + 17,220 + 139,512 = $185,892`	my footing	$139,512
6	Break-even keep-alive cost	`$185,892 / 12 = $15,491 per month; if running Crux for these segments costs more, cancelling dominates on direct economics`	arithmetic on the printed total; the keep-alive cost is not in the record, and I do not state one	$15,491 / month

Facet 4 — Implementation (phases, owners, rollout, cutover, controls, risks)

SEGMENT	ACTION	TIMING	OWNER (RECORD) / CONTROL
GKA · Enterprise · SMB (55)	Transition through the pilot waves; upsell opportunity; light-weight onboarding; API customers (5) need an integration path	pilot waves through H2 2022	transition-plan authors; SV program
Truck brokers (3)	Partner in Transmission (white-label, like ITS); cannot track non-Flexport containers there; else cancel at wind-down	with the Crux wind-down	trucking group; per-customer conversations
Forwarders · 3PL (9)	SV API (no extra dev) or cancel at wind-down	at wind-down	transition-plan authors
Motor carriers (9)	Cancel at wind-down	at wind-down	transition-plan authors
Customs (1) · SCM SaaS (2)	Cancel now	Sept 1 · Aug 1 · Oct 24, 2022	dated in the document

Controls and risks. Commitment step: each impacted party commits to perform, verbally in the decision meeting or by email. Risks named in the record: cost of two systems and the stalled Crux Absorption project; an unwritten parity list; legal concerns over web scraping; cancellations that hand a competitor's consignees to someone else unless timed. **Lean / Kaizen mapping.** Segmenting by what flows through the process is value-stream thinking; the dated cancellations are standard work with a due date; the open questions are the PDCA "Check" I would run first.

Facet 5 — Probe questions (hardest follow-ups, numeric answers)

> **Why not cancel everyone who is not on SV and be done?**
>
> Because the three brokers are 75.0% of containers and 54.7% of nine-row ARR — ITS already uses Transmission and the decision routes AV Logistics and Loadsmart there too. Cancelling them would strand the largest flows to save a template. The other 21 customers are exactly the ones the decision exits or re-routes.

What does it cost to keep Crux alive?

The record has no figure — a reviewer asked the question and it is open. I will not invent one; I give the break-even: the printed total of $185,892 a year is $15,491 a month, so if keeping Crux alive for those six segments costs more than that, cancelling dominates on direct economics. The decision also carried strategic inputs the break-even ignores.

Your totals do not foot. Which ARR is right?

Both, once you say what they are: the printed $185,892 is the six non-SV rows; all nine rows sum to $254,952, and the $69,060 difference is the three SV-bound segments. I lead with container shares because they foot to 294,581, and the appendix lists 77 names against 79 counted — I would confirm that before quoting a per-customer figure.

How many of the 55 will actually move?

The record does not say how many did. What I can show is the shape of the problem: 55 customers, $1,256 average ARR (69,060 / 55), 5 of them API integrations (9.1%) — a long tail suited to light-weight onboarding behind the pilot waves, with six already flagged churned across the whole book (7.6%).

Who disagreed, and what did they get right?

Four inputs: the cost of two systems and the stalled absorption project; a missing, unwritten parity list; "ejecting customers is never a good experience" and the timing of competitor cancellations; and cut-the-competitors. All four were right about something the decision then had to carry — the parity list is the one the record never closes.

How do you know the SMB path is cheap enough?

ARR per SMB customer is $769 against $46,504 per broker, a 60.5× spread — a bespoke migration for 39 accounts at that revenue does not pay, so the SMB path is the standard one. I would price the onboarding hours per account to confirm; there is no record figure.

What would you do on day one of a similar retirement?

Foot the table, find the concentration, write the rule per segment, put the dissent and the open questions on the same page, and date every action. Then price the keep-alive cost before the memo, not after.

BUSINESS IMPACT MODEL — KPI TREE

```
One visibility product to run; every acquired customer has a destination and a date
+- 55 -> Shipment Visibility (GKA 2, Enterprise 14, SMB 39): 69.6% of customers, 13.3% of containers,
27.1% of ARR
+- 3  -> Transmission partners (truck brokers): 3.8% of customers, 75.0% of containers, 54.7% of ARR
+- 9  -> SV API else cancel at wind-down (forwarders 5, 3PL 4)
+- 9  -> cancel at wind-down (motor carriers)
+- 3  -> cancel now, dated (customs 1, SCM SaaS 2)
+- Printed ARR $185,892 = the six non-SV rows; nine rows = $254,952 (footed)
+- Open: keep-alive cost (break-even $15,491 / month); written parity list
(loop)  segment by use -> find concentration -> rule per segment -> dissent on the page -> decider
commits -> dated actions
```

SOLUTION FLOW

```
foot the table -> customers 79, containers 294,581, ARR rows vs printed total
   -> axes per segment: SV serves them? partner or competitor? extra build?
   -> concentration: who carries the containers?
   -> RAPID: Recommend / Agree / Perform / Input / Decide
   -> dissent + open questions on the page -> Decide commits -> each party commits
   -> dated actions: SV waves | partner route | API-or-cancel | cancel now
   -> wind-down of the old front end by the end-2022 goal
```

SENSITIVITY — LOW / BASE / HIGH

KEEP-ALIVE COST (ILLUSTRATIVE)	PRINTED MRR − COST	DIRECT-ECONOMICS READ
$5,000 / month	$15,491 − $5,000 = $10,491	keep Crux for the six segments
$15,491 / month	$15,491 − $15,491 = $0	indifferent
$30,000 / month	$15,491 − $30,000 = −$14,509	cancel dominates on direct economics

The keep-alive cost is not in the record; the three values are illustrative bookends around the break-even. The strategic inputs — competitor timing, partner routes — are not in this arithmetic.

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

> Honestly, retiring Crux was not a money-making decision and I don't dress it as one. The doc's printed total, about one hundred eighty-six thousand a year, is the revenue on the six segments that don't move to Shipment Visibility — I footed the table myself, and all nine rows sum to about two hundred fifty-five thousand. What the analysis changed was the shape of the work: three truck brokers were four percent of customers and seventy-five percent of the containers, so they got a partner route; fifty-five customers — the long tail — move through the pilot waves; nine are API-or-cancel, nine motor carriers cancel at wind-down, three were cancelled on dates. Every customer has a destination and a date. The record doesn't price keeping Crux alive, so I give the break-even — about fifteen and a half thousand a month — and I say the strategic inputs sit outside it. Every dollar here is the document's, footed, or labeled; none of it is claimed as savings.

IF CHALLENGED — THE FULL ANSWERS

> **"You are telling me a $186K book was a good decision to exit?"**
>
> I'm telling you what the record shows: the printed total is the six non-SV segments, and the rule exits or re-routes them by segment, with the brokers — 75% of containers — taking a partner route. Whether the economics beat the keep-alive cost is exactly the number the record never priced; I give the break-even, $15,491 a month, and flag it.

> **"Why trust your footing over the doc?"**
>
> Because the rows foot and the printed total does not: customers foot to 79, containers to 294,581, but the printed ARR equals the six non-transition rows only — the other three rows add $69,060. That is arithmetic, and it is why I use container shares first.

> **"What did you actually decide?"**
>
> The decider decided. My part, as I tell it, was the segmentation, the concentration read and getting the dissent and the open questions on one page beside the recommendation.

20-SECOND VERSION AND NACF BRIDGE

20-SECOND VERSION

When Flexport retired an acquired visibility product, 79 customers needed a destination. I segmented them into nine types, found three truck brokers were 4% of customers and 75% of containers, and wrote a rule per segment: 55 to the new product, three to a partner route, the rest API-or-cancel with dates — with the dissent on the page.

NACF BRIDGE — ONE SENTENCE

Retiring or re-pointing a node or lane in a network is the same problem: segment what flows through it, find the concentration (a few lanes carry most of the volume), give each segment a destination and a date, and price keeping both running — a placement trade-off of cost-to-serve against distance-to-customer.

BEHAVIORAL PACK — FOUR QUESTIONS THIS STORY ANSWERS, EACH A SEPARATE 90-SECOND STAR FROM A DIFFERENT FACET

B1 · "Tell me about a time when you had to balance the needs of the customer with the needs of the business. What did you do? What was the result?" AIQB: Customer Obsession Q8 **Customer Obsession** FACET: SEGMENTATION AND DESTINATIONS

Open (first two sentences): "Every one of seventy-nine customers got a destination, not an end-of-life email. I segmented them by what they actually were and wrote a rule per segment."

90-second STAR. **S** An acquired product with 79 customers and a goal to move them by the end of 2022 — and not every customer fit. **T** Give each customer a path, not a notice. **A** Nine segments, three questions each — does SV serve them, partner or competitor, extra build — giving 55 to Shipment Visibility, three brokers to a partner route, nine API-or-cancel, nine cancel at wind-down and three cancelled on dates. **R** 79 of 79 with a destination and a date; the largest accounts got conversations instead of a template.

Land: 79 of 79: 55 + 3 + 9 + 9 + 3 · **Pivot to NACF:** retiring a lane or node: every flow through it gets a destination and a date before the old path closes.

Do NOT say: "nobody was stranded" or "zero escalations" — the record does not say; dollars as savings.

B2 · "Tell me about a time when you considered everyone who was affected by your work, not just your direct customers or people within your organization." AIQB: Broad Responsibility Q5 **Success and Scale Bring Broad Responsibility** FACET: CONCENTRATION

Open (first two sentences): "Three customers were four percent of the book and seventy-five percent of the containers. A template would have been irresponsible for them and overkill for thirty-nine small accounts."

90-second STAR. **S** A single end-of-life policy would have treated 79 customers alike. **T** Match the effort to what each customer needs and what is at stake. **A** I computed concentration: brokers 3.8% of customers, 75.0% of containers; ARR per customer from $769 (SMB) to $46,504 (broker), 60.5×. The brokers got a partner route and per-customer conversations; the tail got the standard path. **R** Effort followed stakes: partner route for the largest flows, standard path for the tail.

Land: 3.8% of customers = 75.0% of containers · **Pivot to NACF:** a Pareto of lanes or nodes before a network change — the few that carry the volume get bespoke handling.

Do NOT say: that the partner route succeeded — the record shows the decision, not the outcome.

B3 · "Describe a time when you felt really strongly about something on a project but the team decided to go in a different direction. How hard did you press the issue? How did you approach that project afterward?" AIQB: Have a Backbone Q4 **Have Backbone; Disagree and Commit** FACET: THE DISSENT

Open (first two sentences): "The document carried real dissent: the cost of running two systems, a parity list nobody had written down, and a warning that ejecting customers is never a good experience. We put all of it on the page."

90-second STAR. **S** A recommendation to retire a product that others had reasons to keep. **T** Get a decision the organization would commit to, with the objections visible. **A** The RAPID named who recommends, who agrees, who performs, who gives input and who decides; the input section kept each reviewer's words, including the parity and keep-alive questions; the decider committed with those on the page, and each impacted party confirmed they would perform. **R** A decision with named performers and dated actions — and two open questions flagged instead of hidden.

Land: four dissenting inputs; two open questions · **Pivot to NACF:** a network decision memo — putting the cost of the status quo and the unresolved questions beside the recommendation, then committing.

Do NOT say: that I overruled anyone — the decider decided; or what my exact seat was without checking.

B4 · "Tell me about a time when you uncovered a significant problem in your team. What was it and how did you communicate it to your manager and other stakeholders? What did you do to address the problem?"

AIQB: Earn Trust Q6 | Dive Deep | FACET: FOOTING

Open (first two sentences): "When I re-footed the decision document's table, the customer and container counts added up but the dollar total did not — the printed ARR was only six of the nine rows."

90-second STAR. **S** A table everyone quoted: 79 customers, $185,892. **T** Make sure the numbers under a decision were right. **A** I summed each column from its rows: customers 79, containers 294,581, ARR $254,952 against the printed $185,892 — the difference, $69,060, is exactly the three SV-bound segments. I switched the analysis to container shares and flagged the 77-versus-79 name count. **R** The decision rested on numbers that foot; the dollar total was relabeled as the exit segments' ARR.

Land: $254,952 vs $185,892; difference $69,060 · **Pivot to NACF:** every network metric gets footed from its rows before a decision — totals that silently drop a segment are the commonest error.

Do NOT say: that I caught it live in the room — say "when I re-footed it preparing this".

SAME STORY, THREE ANGLES — THREE CARDS, THREE OPENERS, THREE METRICS, THREE LPS

Data / analytical angle — Dive Deep

Opener: "Three customers were under four percent of the book and three-quarters of the containers — so the plan could not be one policy."

Headline metric: 3.8% of customers = 75.0% of containers = 54.7% of ARR

- Foot first: containers foot, the printed ARR does not.
- Concentration: 3 brokers vs 39 SMBs — $46,504 vs $769 per customer.
- The SV-bound 55 are the long tail: 69.6% of customers, 13.3% of containers.
- Say "my footing" once, early.

Conflict / influence / backbone angle — Have Backbone; Disagree and Commit

Opener: "The document carried real dissent, and the decision was only as strong as the objections left standing on the page."

Headline metric: four dissenting inputs; one decider; each impacted party commits

- Cost of two systems; a missing parity list; ejecting customers; cut the competitors.
- RAPID: Recommend, Agree, Perform, Input, Decide named.
- The decider committed with the objections recorded.
- My part: the comparison, the per-segment pricing and the dissent on one page; the decider was an executive.

Honest failure-and-learning angle — Learn and Be Curious

Opener: "The decision memo had two questions it could not answer — what Crux costs to keep running, and whether the feature-parity list was written down — and the record never closes either."

Headline metric: 2 open questions; break-even $15,491 / month

- What I would do differently: price the keep-alive cost before the memo, not after.
- What I would add: a written parity matrix as an exit criterion for each segment.
- What held: dated actions and named performers.
- No dollar claimed as savings.

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS

"You quote 79 customers and $185,892. Your own table says $254,952. Which is it?"

Numeric answer. Both, and I say what each is: $185,892 is the six non-transition rows (24 customers); the three SV-bound rows add $69,060 for $254,952. Customers (79) and containers (294,581) foot either way, so container shares lead. The appendix lists 77 names against 79 counted, so I would confirm before quoting a per-customer average.

Say exactly: "The printed total is the six segments that don't move to Shipment Visibility; all nine rows sum to about two hundred fifty-five thousand. Customers and containers foot either way, so I lead with container shares."

"What if the three brokers refuse the partner route?"

Numeric answer. Then they cancel at wind-down per the decision, and the exposure is the largest in the book: 221,044 containers (75.0%) and $139,512 (54.7% of nine-row ARR). One of three already uses Transmission, which is why it is the route; the other two are per-customer conversations, not a template.

Say exactly: “If they decline, they cancel at wind-down — and that is seventy-five percent of the containers, which is exactly why they got per-customer conversations instead of a template.”

"What number would have flipped your decision to exit the forwarders and 3PLs?"

Numeric answer. The keep-alive cost. The nine customers pay $17,220 a year; the six exit segments together pay $15,491 a month. If keeping Crux alive costs less than that monthly figure, deferral wins on direct economics; the record never prices it, which is why I would price it before the memo.

Say exactly: “The keep-alive bill. The six exit segments pay fifteen thousand four hundred ninety-one a month; if running Crux costs less than that, deferral wins — and the record never prices it.”

S12 — Flexport — FF App export launch: re-sequencing a committed 18-month roadmap on cost-to-serve evidence (value in month 6, 66% less effort, ~$5M cost avoidance)

DEEPENED

LPs this story can serve here: Think Big (primary — the flip) · Frugality (primary — ~$5M avoided by sequencing) · Have Backbone, Disagree & Commit (changing the manager's plan) · Earn Trust (privately first) · Bias for Action (the reversal trigger written before the swing)
Process family: Deliver — export documentation / operator and partner workflow; launch sequencing; unit-economics-driven roadmap governance

SAFE-SAY — TWO SENTENCES TO SAY EXACTLY

Most attackable number. “About five million dollars of avoided cost — engineering effort never spent plus value pulled forward — said once, an avoidance and not a saving, and never added to the unit-cost arithmetic.”

“What's your source for that?” “It is the figure in my own interview workbook for the export-app re-plan; my split into engineering effort and value pulled forward comes to about four point four million, a model I label as mine, so I say about, and I never call it annual.”

LEADERSHIP PRINCIPLES THIS STORY CARRIES — ONE-LINE PROOF SENTENCE EACH

Think Big The destination changed — first value in month 6 instead of month 18, and half again the unit saving — by re-opening a committed, socialized roadmap on evidence at the work-item grain.

Frugality About $5M of cost avoidance — engineering never spent plus value pulled forward — said once; 66% less effort to first value; a reuse rule for any module over 8 dev-weeks.

Have Backbone; Disagree and Commit I changed my manager's plan privately first, gave engineering two days to break the model, and the onsite ratified it with his name on it.

Earn Trust The cost of the trade — operators on the old screens two more quarters — was priced and published, not hidden.

Honesty label. The roadmap was my manager's; I owned the sequencing recommendation. Engineering produced the re-estimates; the ~$5M is the record's cost-avoidance figure, said once; the run-rate decomposition and the engineer-count split are my model. Loop-packet conflict (§1.3): that document tells this as a Sephora roadmap — the record is Flexport FF App; say Flexport.

WHAT IS THE FF EXPORT APP? — THE ONE-MINUTE EXPLAINER (FROM THE PROGRAM DOCUMENTS; RECORD-FROM-DOCS)

The minute. The Freight Forwarding App — "FFA" — is Flexport's operator-facing execution platform: where import and export shipments actually get run. Its core tenet is work-item-driven execution — every unit of work is a work item assigned to exactly one operator ("one operator, one work item"), so nothing ships on tribal knowledge and every action is attributable. For export, the heart of it is schedule management: a "Generate Schedule" work item builds the shipment's milestone schedule automatically, and a "Replan Schedule" work item fires on defined exceptions — an LCL CFS-cutoff miss, a vessel late against truck pickup, a vessel late past the quoted delivery date, a change of vessel — each with a defined rework path instead of ad-hoc heroics. It shipped FCL first (2022), with Air and LCL behind it (2023). RECORD-FROM-DOCS

The machinery behind the story. The schedule work sat inside a five-work-stream FFA program (Schedule Management; Cascading Schedules; Auto-Build Initial Schedule; End-to-End Operator Experience; Operator MiMeC), with schedule automation completing end Q3/early Q4 2022 and export-partner UAT aimed at a March 2023 launch. Because the app serves external partner organizations, it also carries a compliance bar: an immutable audit log of who changed what and when — nine event categories at a 100%-captured standard across ~100 partner orgs and thousands of changes a day, phased Alpha → Beta → MVP with CISO sign-off. RECORD-FROM-DOCS

Doc-vs-canon footnotes: the module documents carry forward-plan dates (export-partner UAT March 2023; schedule automation completing end Q3/early Q4 2022) — the build-out clock after MVP. Canon's "value in month 6" is the sequencing decision's clock: different milestones, no conflict — never merge them. The audit-logs "~100 partner orgs" is platform-wide; canon's 53 is the import-partner migration set — never merge those either.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. The Freight Forwarding App export roadmap was operator-first — 18 months to first value, already socialized, with my manager's name on it. The process baselines were 339.5 minutes of handling per shipment and 2,200 operator interactions per departed shipment. The question nobody had asked was time-to-value and unit cost — the plan had been built around persona preference. **Task.** With no authority over the roadmap, re-sequence it on cost-to-serve evidence without abandoning the operators. **Action.** I wrote the baseline memo, had the business cut a bare-minimum scope per persona, and got engineering to re-estimate with confidence levels: operator-first reached −25% cost-to-serve in 9 months with operators still spending 20% of their time in the old app; partner-first reached −50% in 6 months and built the chassis operators would later ride. I added a rebuild-vs-reuse rule per module — over eight dev-weeks, reuse — a scope tripwire in the burn-up, and a written reversal trigger, then read it to my manager privately first; engineering had two days to break it, and the Bellevue onsite ratified the flip with his name on it. Operators' two further quarters on old screens were priced and published, not hidden. **Result.** Primary metric: engineering effort to first value — the 18-month plan → 66% less effort, value in month 6 instead of 18. ~$5M of cost avoidance — the record figure, said once; cost-to-serve −50% versus −25% at the work-item grain; 48 of 53 import partners migrated within a month.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — The inherited launch plan for the freight-forwarding app was operator-persona first, 18 months, already socialized, and my manager owned it. Process baselines: 339.5 minutes of handling per shipment and 2,200 operator interactions per departed shipment — the two numbers everything prices from.

The business problem was time-to-value and unit cost, not persona preference. Left as inherited, operators would reach first value in month 18 while still spending 20% of their time in the old app — half the unit saving (−25% vs −50% at the work-item grain), reached a year later. The risks of re-opening it: a committed, socialized plan; optimistic estimates; and operators feeling abandoned while partners went first.

T — Own the sequencing recommendation — and change a plan with my manager's name on it, without authority over the roadmap, in a way he could own.

Baselines on the table: 339.5 min/shipment · 2,200 operator interactions per departed shipment · first value in month 18 on the inherited path · cost-to-serve −25% (operator-first) vs −50% (partner-first) at the work-item grain.

KEY CHALLENGES — WHAT THE PROGRAM RECORD ADDS (FROM THE PROGRAM DOCUMENTS; RECORD-FROM-DOCS)

- **Asia latency surfaced right after the April 2022 import-side launch.** The monthly business review read P95 page load at 21.19s in Asia against 3.3s in the US; static assets ran ~5s in China against ~500ms in the US; the app's domain had no geo-based DNS or reverse proxy, so Asia traffic rode the public internet. The fixes were sequenced — WAF enablement, a double CDN removed, a regional CDN proposal with smoke tests per change, then China and Asia tuning — with 48 of 53 import partners (about 90%) already migrated and expecting the app to hold. RECORD-FROM-DOCS
- **Compliance was a launch feature, not an afterthought.** The Audit Logs PRD demanded an immutable who/what/when trail across ~100 partner orgs and thousands of changes a day — nine categories at a 100%-captured bar, phased Alpha → Beta → MVP — and the CISO's definition of "important events" was deliberately vague, so PM buy-in and CISO sign-off were written into the plan as the mitigation. RECORD-FROM-DOCS
- **Exceptions had to become work items.** Replanning ran on a defined taxonomy — LCL CFS-cutoff miss, vessel late vs truck pickup, vessel late past quoted delivery date, change of vessel — each with a rework path, under the

"one operator, one work item" tenet. The exception list, not the happy path, is where operator trust is won. RECORD-FROM-DOCS

- **A hard external deadline.** Export-partner launch UAT was set for March 2023, with schedule automation completing end Q3/early Q4 2022 and FCL ahead of Air/LCL — a date-driven constraint on top of the unit-economics sequencing. RECORD-FROM-DOCS

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery** — baseline memo (339.5 min; 2,200 interactions); bare-minimum scope per persona cut with the business; the question restated as time-to-value and unit cost. *Exit bar:* business signs the bare minimums; engineering agrees to re-estimate with confidence levels.
- **Plan & Design** — re-estimates 9 months (operator) vs 6 months (partner) with confidence buffers (×1.0 / ×1.4 by confidence, +15% testing); the 20%-still-in-old-app finding; work-item-grain cost-to-serve translation (−25% vs −50%); rebuild-vs-reuse rule per module (>8 dev-weeks → reuse; rank by benefit × impact ÷ dev-weeks); reversal trigger written; read privately to my manager first; engineering given two days to break it. *Exit bar:* my manager puts his name on the flip at the Bellevue onsite; sequencing signed.
- **Build & Test** — 15 domains × 6 modules; Jira burn-up with the scope tripwire — new work estimated and swapped, never absorbed; operator-interactions-eliminated as the success metric; the tenet "no go-live without every work item assigned to one operator." *Exit bar:* burn-up 55.8% → 83.2% across two quarters; every work item owned.
- **Cutover & Go-Live (waves)** — the import-side app live April 2022 with 11 partners in 10 countries; partner migration plan published; operators' two further quarters on old screens priced and published. *Exit bar:* 48 of 53 import partners migrated within a month.
- **Hypercare / Close** — tracked interactions eliminated against the 2,200 baseline by work item; sequenced FCL 2022 → Air/LCL 2023 off that read; close-out at ~$5M cost avoidance and 66% less effort. *Exit bar:* value in month 6 instead of 18; operators moved onto the shared chassis on the published schedule.

Influence and ownership. Mine: the baseline memo, the comparison model, the rebuild/reuse rule, the scope tripwire and the reversal trigger. The business signed the bare minimums; engineering produced the re-estimates; my manager signed the sequencing and owned the flip. He argued two points, I adjusted one, and the onsite ratified it — I have never won a disagreement by seniority; I rank, privately first, and let the room ratify.

> **Designed the process; others own it now.** I designed the comparison model, the rebuild-vs-reuse rule and the scope tripwire; the delivery teams run the burn-up and the swap rule, and the owner of the original plan owned the flip. **Trade-off put to leadership.** The recommendation to leadership put the competing metrics side by side — time-to-first-value and partner cost-to-serve (6 months, −50%) vs operator effort (9 months, −25%) — with the operators' two further quarters on old screens priced, not hidden.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY (CANON NUMBERS ONLY)

- **$** — ~$5M cost avoidance (record, said once — never "avoidance" and "annual reduction" as two results); underneath it a ≈$1.5M/yr run-rate *modeled* at −50% CTS on an illustrative 20K export shipments; the decomposition ≈$2.9M engineering avoided + ≈$1.5M pulled forward ≈ $4.4M is my model, within ~12% of the record.
- **#** — 48 of 53 import partners migrated within a month; the import-side app live April 2022 with 11 partners in 10 countries; baselines 339.5 min/shipment and 2,200 interactions (record).
- **%** — engineering effort to first value −66%; CTS −50% partner-first vs −25% operator-first at the work-item grain; burn-up 55.8% → 83.2% across two quarters (record).
- **Time** — first value in month 6 instead of month 18 (record); FCL 2022 → Air/LCL 2023 sequenced off the interactions read.
- **Customer** — partners completed end-to-end in the new app; operators' two further quarters on old screens priced and published, not hidden (record).
- **Quality** — new scope estimated and swapped, never absorbed; no go-live without every work item assigned to one operator (record).

L6 LEVEL EVIDENCE — what the interviewer pattern-matches against the Amazon L6 functional rubric; every line is this story's canon, no new numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	An 18-month committed roadmap with no cost-to-serve read behind it. I restated the question as time-to-value and unit cost, built the baseline memo (339.5 min; 2,200 interactions) and set the success metric — operator interactions eliminated.
Scope & influence	15 domains × 6 modules; the business signed the bare minimums, engineering produced the re-estimates, my manager signed the sequencing and owned the flip at the onsite — influence on the owner of the original plan, one level up.
Execution trade-off + mechanism others now own	Partner-first (6 months, −50% CTS) vs operator-first (9 months, −25%), with the operators' two further quarters on old screens priced and published. Mechanism others own now: the rebuild-vs-reuse rule per module and the scope tripwire on the burn-up.
Impact (long-term)	~$5M cost avoidance (record); first value in month 6 instead of 18; FCL 2022 → Air/LCL 2023 sequenced off the interactions read; 48 of 53 import partners migrated within a month.
Process improvement (standard work institutionalized)	Confidence-buffered estimates (×1.0 / ×1.4, +15% testing); the tenet "no go-live without every work item assigned to one operator"; new scope estimated and swapped, never absorbed.
Complexity & consensus	A disagreement with my manager, privately first and with numbers; two days for engineering to break the model; his name on the flip — the onsite ratified it.
Root cause at scale	The 20%-still-in-old-app finding and the work-item-grain cost-to-serve translation located where value actually accrued, so sequencing ran on unit economics rather than feature count.

PROBING — CHALLENGE Q&A TUNED TO THIS INTERVIEWER

HM — You changed your manager's plan. How, and would you do it to me?

Privately first, with the numbers — 9 versus 6 months, 20% still in the old app, −25% versus −50%. He argued two points, I adjusted one, and the onsite ratified it with his name on it. Yes — the same way: the model, the owner named, the reversal trigger written, and two days for your engineers to break it before anyone else sees it.

HM — Is the $5M a saving or an avoidance?

Avoidance — engineering effort never spent plus a year of unit savings pulled forward — and I say it once. The recurring run-rate underneath is a separate, smaller modeled number (≈$1.5M/yr on an illustrative 20K shipments); I never present the avoidance as an annual reduction.

HM — What stopped the operators from being abandoned?

A priced, published two-quarter schedule — the trade was visible and scored, not hidden — and the partner backend was the chassis operators later rode, so their move got cheaper, not later.

HM — Your engineer count and rate are yours, not the program's.

Correct — twelve engineers at $20K a month are my numbers; the record does not itemize the $5M. At 10–15 engineers and $15–25K the effort piece runs $1.8–4.5M; adding the pulled-forward run-rate (≈$1.5M at the base) puts the whole decomposition at $2.9–6.7M, and the ~$5M record figure sits inside that range — the effort piece alone does not reach it. I would firm it with the two scoping envelopes (66.2 and 99.8 engineer-months) and Finance's loaded rate.

HM — What made the big swing safe?

Three mechanisms: confidence buffers on low-confidence estimates, a written reversal trigger, and the scope tripwire in the burn-up — new work estimated and swapped, never absorbed — which is why the burn-up read 55.8 → 83.2% honestly.

HM — Lesson, and how it shows up in your first quarter here?

Bring the model, name the owner, write the reversal trigger. In the first quarter: re-baseline any committed plan in time-to-value and unit cost at the work-item grain before defending or changing it.

> **HM — What broke after the April 2022 import-side launch that the plan had not seen?**
>
> Asia latency RECORD-FROM-DOCS: the business review showed P95 page load at 21.19 seconds in Asia against 3.3 in the US — static assets ~5s in China against ~500ms in the US — because the domain had no geo-based DNS or reverse proxy and Asia traffic rode the public internet. The fix was infrastructure sequencing, not re-architecture: WAF enablement, the double CDN removed, a regional CDN proposal with smoke tests per change, China tuning then Asia tuning. The lesson imported into every later plan: the pilot's geography is a performance requirement, not a rollout detail.

> **HM — What compliance bar does a partner-facing app carry, and what did it cost?**
>
> An immutable audit trail RECORD-FROM-DOCS: who/what/when for logins, work-item changes, route updates, messages, documents, schedule updates, exceptions, assignment rules and permission changes — nine categories at a 100%-captured bar, across ~100 partner orgs and thousands of changes a day. The honest cost answer: the PRD phased it Alpha → Beta → MVP precisely because capturing everything on day one was not feasible; the residual risk — the CISO's vague "important events" — was mitigated with sign-off, not silence.

> **HM — What did the March 2023 export-partner deadline change about the sequencing?**
>
> It made the module order do double duty RECORD-FROM-DOCS: schedule automation had to complete by end Q3/early Q4 2022 so UAT could start for the March 2023 export-partner launch, and FCL went ahead of Air/LCL because that is where the volume and the interactions baseline (2,200 per departed shipment) lived. The unit-economics sequencing and the deadline sequencing pointed the same way — which is exactly what made the flip ratifiable at the onsite.

THE KEY MATH — THE TWO PATHS AT THE WORK-ITEM GRAIN, AND THE RECORD'S ~$5M SAID ONCE

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	CTS per shipment	`339.5 min × $0.45/min ≈ $153`	record inputs; blended loaded rate derived, labeled	≈$153/shipment
2	Operator-first path	`9 months → −25%; operators still 20% in old app`	engineering re-estimates (record)	≈$38/shipment saved, month 18 to full value
3	Partner-first path	`6 months → −50%; partner backend = the chassis`	engineering re-estimates (record)	≈$76/shipment saved, 12 months earlier
4	Effort to first value	`100 − 66 = 34% of the inherited path`	record	−66%
5	Run-rate	`$76 × 20,000 export shipments = $1.52M`	volume illustrative (modeled)	≈$1.5M/yr modeled
6	Decomposition of the avoidance	`12 eng × 18 mo × 66% × $20K ≈ $2.9M + 12 mo × $1.5M = $1.5M → $4.4M`	counts and rate mine; within ~12% of the record	~$5M record headline, said once
7	Confidence rule	`(10 × 1.0 + 10 × 1.4) × 1.15 = 27.6 wks vs 20 naive`	two illustrative 10-week modules	buffers inflate only low-confidence items

Burn-up trajectory 55.8 → 63.3 → 66.0 → 69.3 → 76.0 → 83.2% (record). Rebuild-vs-reuse threshold of 8 dev-weeks was the engineering median (record rule).

Where this lands at Amazon. Think Big with Frugality attached — re-open a committed plan when the goal matters more than the plan, price it in unit economics, and have the owner whose name was on the original ratify the change. For a NACF process roadmap: sequence by time-to-value and cost-to-serve at the work-item grain, with a reversal trigger and a scope tripwire written before the swing.

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE WITH S12

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Tell me about a time you thought big / changed the direction of a program.	Think Big	The destination changed — value in month 6 not 18 — on evidence at the work-item grain; the mechanisms that made the swing safe.	Do not tell it as a Sephora story (loop-packet conflict); the record is Flexport.
Tell me about a time you saved money / did more with less.	Frugality	~$5M avoided by sequencing, said once; 66% less effort; rebuild-vs-reuse over 8 dev-weeks.	Never "$5M annual cost reduction" in the same breath as the avoidance.
Tell me about a time you disagreed with your manager.	Have Backbone	Private first, with numbers; two days for engineering to break it; his name on the flip at the onsite.	Skip S14 (the quiet-fix refusal) — held for the bar raiser.
How do you prioritize when everything is committed?	Functional — roadmap governance	Benefit × impact ÷ dev-weeks per module; new work estimated and swapped, never absorbed; the burn-up as the honest read.	Do not claim the roadmap was mine — it was my manager's.
Tell me about a trade-off you made that hurt someone.	Earn Trust / Customer Obsession (internal)	Operators on old screens two more quarters — priced, published and scored, not hidden.	Do not present the operator delay as costless.
What's a decision you'd reverse if the data changed?	Are Right, A Lot	The reversal trigger was written before the flip; the interactions-eliminated read sequenced Air/LCL 2023, not a date on a slide.	No YoY framing; the avoidance is one-time.
How does re-sequencing a roadmap relate to launch readiness? (transferability probe — public-profile inference)	Functional — transfer	Her world is 50+ FC launches: readiness discipline is the same shape as the flip — a baseline memo (the readiness scorecard), gates that fire on evidence (the reversal trigger ≈ a launch-readiness gate), and the owner of the original plan ratifying the change. Sequence by time-to-value at the work-item grain, never by the date on the slide.	Do not claim FC-launch experience; bridge from the mechanism, not the domain.
How would you apply cost-to-serve thinking to a placement network? (transferability probe)	Functional — transfer	CTS per container is cost-to-serve at one node grain; placement is the same arithmetic at the node's position — distance-to-customer priced against speed and cost per unit moved. The work-item grain (339.5 minutes; 2,200 interactions) is how I keep it honest.	Never quote her $50MM / $80MM savings as shared ground — those are her numbers, framing only.

DEEPENING S12 — FIVE FACETS, FOUR-TABLE MATH, BEHAVIORAL PACK, ANGLES AND TRAP DRILLS NEW

FIVE FACETS AT A GLANCE — the labeled structure the probing section below follows

1 · Data analysis	Baseline memo: 339.5 minutes per shipment and 2,200 interactions per departed shipment; per-persona bare-minimum scope; re-estimates by path at the work-item grain; the 20% still in the old app.
2 · Solution design	Operator-first vs partner-first; rebuild vs reuse by module; confidence buffers; swap-never-absorb scope tripwire; a written reversal trigger; the manager's name on the flip.
3 · Math & data logic	Four tables: $152.78 ≈ $153; −25% vs −50%; 18 → 6 months; −66% ⇒ 34%; 27.6 vs 20 weeks; $2.85M + $1.52M ≈ $4.4M vs the ~$5M record.
4 · Implementation	15 domains × 6 modules; burn-up 55.8% → 83.2%; import-side app live April 2022 with 11 partners in 10 countries; 48 of 53 import partners (about 90%) migrated; FCL 2022, Air and LCL 2023; the export launch is the later Q1 2023 milestone.
5 · Probe questions	Seven numeric probes plus three trap drills: avoidance vs saving, invented engineers, and the 27.6-week rule.

Facet 1 — Data analysis: what each analysis decided

ANALYSIS	DATA AND GRAIN	WHAT IT SHOWED	DECISION IT DROVE
Baseline memo	minutes and interactions per departed shipment	339.5 min and 2,200 interactions — the two numbers everything prices from	the debate became arithmetic, not persona preference
Cost-to-serve translation	339.5 min × ≈ $0.45 per min (derived blend)	$152.78 ≈ $153 per shipment	each path priced as a percent of $153
Re-estimate by path	engineering re-estimates with confidence levels, work-item grain	operator-first 9 months, −25%; partner-first 6 months, −50%	partner-first, with operators on the shared chassis later
Legacy residue	share of operator time still in the old app	20% under operator-first	caps operator-first at half the unit saving
Module cost vs benefit	dev-weeks per module; benefit × impact	median 8 dev-weeks (record rule)	over 8 dev-weeks → reuse, ranked by benefit × impact ÷ dev-weeks
Burn-up	completed ÷ pointed work	55.8 → 63.3 → 66.0 → 69.3 → 76.0 → 83.2% over two quarters	new work estimated and swapped, never absorbed

Facet 2 — Solution design: options weighed

QUESTION	OPTIONS	CHOSEN	WHY
Who goes first	Operators (inherited) · partners · both in parallel	Partners first; operators ride the same chassis later	6 months and −50% against 9 months and −25%; the partner backend is reused, so operator work gets cheaper, not later.
Build or reuse	Rebuild each module · reuse legacy · rule by size	Over 8 dev-weeks → reuse	Engineering's own median; module by module, not ideology.
Estimate honesty	Single-point estimates · confidence buffers	× 1.0 / × 1.4 by confidence, plus 15% testing buffer	Buffers only inflate low-confidence items: 27.6 weeks against 20 naive.

QUESTION	OPTIONS	CHOSEN	WHY
Change control	Absorb new scope · swap	Estimate and swap, never absorb	The burn-up reads honestly: 55.8 → 83.2%.
How to change the plan	Escalate over the manager · private first with numbers	Private first, two days for engineering to break it, then the room ratifies	The fastest path to a better decision was making it his decision.

Facet 3 — Math & data logic (four tables: Before · Fix substituted · After · Dollars)

Table 1 — Before: the problem in numbers

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Inherited plan	`operator-persona first: 18 months to first value, socialized, my manager's plan`	record	month 18
2	Unit baselines	`339.5 minutes of handling per shipment; 2,200 operator interactions per departed shipment`	record	the two numbers everything prices from
3	Cost-to-serve per shipment	`339.5 min × $0.45 per min = $152.78 ≈ $153`	record inputs (FCL $0.56, Network $0.61, Data $0.24 per min; the blend is derived, labeled)	≈ $153 per shipment
4	Operator-first path	`9 months to −25%; operators still spend 20% of their time in the old app`	engineering re-estimates (record)	−25%, capped by legacy residue

Table 2 — The fix: paths, rules and tripwire, values substituted

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Partner-first path	`6 months to −50%; the partner backend is the chassis operators later ride`	engineering re-estimates with confidence levels (record)	−50%, 12 months earlier
2	Unit saving per path	`$153 × 50% = $76.50 ≈ $76; $153 × 25% = $38.25 ≈ $38`	from Table 1	double the unit saving
3	Effort to first value	`100 − 66 = 34% of the inherited path`	record	−66% ⇒ 34%
4	Confidence rule	`(10 × 1.0 + 10 × 1.4) × 1.15 = 27.6 weeks against 20 naive; 27.6 / 20 = +38%`	two illustrative 10-week modules; the multipliers and 15% buffer are the record rule	27.6 vs 20 weeks
5	Rebuild-vs-reuse	`dev-weeks > 8 → reuse; rank by benefit × impact ÷ dev-weeks`	the 8-week rule was engineering's median (record rule)	module by module
6	Scope tripwire	`burn-up 55.8 → 83.2% = +27.4 points over two quarters; new work swapped, never absorbed`	record	+27.4 points

Table 3 — After: before → after

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Time to first value	`month 18 → month 6`	record	12 months earlier
2	Engineering effort to first value	`100% → 34%`	record	−66%

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
3	Cost-to-serve per shipment	≈ $153 → ≈ $76 (−50%)	record inputs; derived	≈ $76
4	Partners migrated	48 of 53 import partners within a month: 48 / 53 = 0.9057 → about 90% (the documents print 90.5%)	record (resume, Asia-latency doc); ratio mine	48 of 53 — about 90%
5	Pilot reach	import-side app live April 2022 with 11 partners in 10 countries; 15 domains × 6 modules = 90 modules	record; product mine	11 partners · 90 modules

Table 4 — The dollars: every multiplication shown; the ~$5M said once

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Unit saving	$153 × 50% = $76 per shipment	from Table 2	≈ $76
2	Run-rate	$76 × 20,000 export shipments = $1,520,000	modeled (volume illustrative)	≈ $1.5M a year
3	Engineering avoided	12 eng × 18 mo = 216 eng-months; × 66% = 142.6; × $20,000 = $2,851,200	modeled (counts and rate mine; benchmark $15–25K)	≈ $2.9M one-time
4	Value pulled forward	12 months × ($1.52M ÷ 12) = $1.52M	modeled, from the run-rate	≈ $1.5M one-time
5	Decomposition check	$2.9M + $1.5M = $4.4M; ($5.0M − $4.4M) / $5.0M = 12% under the record	modeled on rounded inputs; the ~$5M is the record, said once	$4.4M vs ~$5M

Facet 4 — Implementation: the flip, the build and the cutover

PHASE	WHAT HAPPENED (RECORD UNLESS MARKED)	CONTROL
Decide	private read to my manager first; engineering two days to break the model; the onsite ratifies with his name on the flip	reversal trigger written before the flip
Build	15 domains × 6 modules; Jira burn-up 55.8% → 83.2% across two quarters; no go-live without every work item assigned to one operator	scope swapped, never absorbed
Cutover	import-side app live April 2022 with 11 partners in 10 countries; 48 of 53 import partners (about 90%) migrated within a month; operators' two further quarters on old screens priced and published	partner migration plan published
Sequence	FCL 2022, then Air and LCL 2023, read off interactions eliminated against the 2,200 baseline	by work item

Lean / Kaizen mapping. Time-to-value is the lead-time waste; the 20% still in the old app is inventory of unfinished transition; the rebuild-vs-reuse rule is standard work for the make-or-reuse decision; the swap-never-absorb tripwire is a pull system for scope; the written reversal trigger is the PDCA "Check" fixed in advance.
Honest note. The record's single engineering-effort figure is −66%; the effort-envelope numbers sometimes quoted alongside it are not used here.

Facet 5 — Probe questions (numeric)

> **Saving or avoidance? Annual?**
>
> Avoidance, one-time, said once: about $5M, record. My decomposition — $2.85M of engineering never spent plus $1.52M of unit saving pulled forward — is $4.4M, within 12% of it. The recurring run-rate underneath, $1.52M a year, is a separate modeled number; I never present the avoidance as annual.

Your engineers and rate are invented.

They are my model, and I say so: ten to fifteen engineers at $15–25K a month moves the effort piece from $1.8M to $4.5M; with the pulled-forward piece, the decomposition ranges $2.9M to $6.7M, and the record's ~$5M sits inside that range — not inside the effort piece alone.

Why 27.6 weeks and not 20?

(10 × 1.0 + 10 × 1.4) × 1.15 = 27.6: the 1.4 applies only to the low-confidence module and the 15% is testing buffer, so the plan is 38% longer than naive and honest about which parts are risky.

Why is partner-first twice the saving?

Because at the work-item grain operator-first reaches −25% in 9 months with 20% of operator time still in the old app, and partner-first reaches −50% in 6 months: $76 against $38 per shipment, 12 months earlier.

Why 8 dev-weeks?

It was engineering's median module cost — the record rule — so the threshold is theirs, not mine: over 8 dev-weeks, reuse; otherwise rebuild, ranked by benefit × impact ÷ dev-weeks.

What did operators pay?

Two more quarters on the old screens — priced, published and scored, not hidden. The partner backend was the chassis they later rode, so their move got cheaper, not later.

What broke after the April 2022 import-side launch?

Asia latency — the monthly review showed 21.19 seconds at P95 against 3.3 in the US; see S12-A for the full investigation. The lesson: the pilot's geography is a performance requirement, not a rollout detail.

SENSITIVITY — LOW / BASE / HIGH

CASE	EFFORT INPUTS	ENGINEERING AVOIDED (ONE-TIME)	EXPORT SHIPMENTS	RUN-RATE / PULLED FORWARD	DECOMPOSITION TOTAL
low	10 engineers × $15,000	$1.8M	15,000 shipments	$1.1M	$2.9M
base	12 engineers × $20,000	$2.9M	20,000 shipments	$1.5M	$4.4M
high	15 engineers × $25,000	$4.5M	30,000 shipments	$2.3M	$6.7M

Rows are modeled, not record; the program's ~$5M is the single signed figure and the base decomposition ($4.4M) is within 12% of it. Note: the high case here reads $6.7M on unrounded inputs (the master rounds to $6.8M).

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

About five million of cost avoidance, and I say that once. Roughly two point nine of it is engineering effort we never spent — sixty-six percent less on a plan that was eighteen months long — and about one and a half is a year of unit savings pulled forward because value landed in month six instead of month eighteen. Behind that sits a run-rate of about a million and a half a year at half the cost-to-serve on twenty thousand export shipments. The sixty-six percent, the six versus eighteen months and the minus fifty versus minus twenty-five are the record; the five million is the program's signed figure; the split and the shipment volume are my model.

IF CHALLENGED — THE FULL ANSWERS

"Twelve engineers and twenty thousand a month are yours, not the program's."

Correct, and the record does not itemize the five million, so I modeled the split. At ten to fifteen engineers and $15–25K a month the effort piece is $1.8M–$4.5M and the whole decomposition $2.9M–$6.7M; the record's ~$5M sits inside the decomposition range.

"Where do twenty thousand shipments come from?"

An illustrative FCL export volume, and the softest input: at 15,000 to 30,000 the run-rate runs $1.14M to $2.28M. I would replace it with the departed-shipment count from the system that produced the 2,200-interaction baseline.

"Are you double counting the pulled-forward value and the five million?"

No. The five million is the total; the pulled-forward year is one slice of how it decomposes, and the run-rate underneath is not a second result.

20-SECOND VERSION AND NACF BRIDGE

20-SECOND VERSION

At Flexport I re-sequenced a committed 18-month roadmap on cost-to-serve evidence — partners first, operators on the same chassis later — so value landed in month 6, effort to first value fell 66%, and the program recorded about $5M of cost avoidance.

NACF BRIDGE — ONE SENTENCE

It is the discipline of sequencing launches or placement moves by time-to-value at the unit grain, with a written reversal trigger and the owner of the original plan ratifying the change.

BEHAVIORAL PACK — FOUR QUESTIONS THIS STORY ANSWERS, EACH A SEPARATE 90-SECOND STAR FROM A DIFFERENT FACET

B1 · "Give me an example of how you have changed the direction or view of a specific function/department and helped them embrace a new way of thinking. Why was a change needed? What was the outcome?"

AIQB: Think Big Q2 | Think Big | FACET: SOLUTION DESIGN

Open (first two sentences): "The roadmap said eighteen months to first value, operators first. I re-opened it, and the new plan put value in month six and delivered twice the unit saving."

90-second STAR. **S** A committed, socialized 18-month plan owned by my manager. **T** Change the plan without authority over the roadmap, in a way he could own. **A** I priced both paths at the work-item grain — partner-first 6 months and −50%, operator-first 9 months and −25% with 20% of operator time still in the old app — added confidence buffers, a rebuild-vs-reuse rule, a scope tripwire and a written reversal trigger. **R** First value in month 6 instead of 18; effort to first value −66%; ~$5M cost avoidance, said once.

Land: 18 → 6 months; −66% effort · **Pivot to NACF:** sequencing launches by time-to-value at the unit grain.

Do NOT say: "$5M annual savings" or the roadmap as mine.

B2 · "Tell me about a time when you strongly disagreed with your manager or peer on something you considered very important to the business. What was it and how did you handle it? Knowing what you know now, would you do anything differently?" AIQB: Have a Backbone Q1 **Have Backbone; Disagree and Commit** FACET: IMPLEMENTATION

Open (first two sentences): "The plan had my manager's name on it. I read it to him privately first, with the numbers, and gave engineering two days to break my model before anyone else saw it."

90-second STAR. **S** A plan my manager owned, with socialized commitments. **T** Change it without becoming a political fight. **A** Private read; he argued two points and I adjusted one; engineering got two days to break the model; the onsite ratified with his name on the flip. **R** He owned the flip; the plan changed; the model survived.

Land: two points argued, one adjusted · **Pivot to NACF:** changing a launch sequence: model first, private first, owner of the old plan on the new one.

Do NOT say: that I won on seniority or escalated — I never have.

B3 · "Give me an example of how you have helped save costs or eliminate waste within your role or organization. What was the situation? What was the impact?" AIQB: Frugality Q1 **Frugality** FACET: MATH AND DATA LOGIC

Open (first two sentences): "About five million dollars of cost avoidance — engineering we never spent plus a year of unit savings pulled forward — and I say it once, because it is avoidance, not an annual reduction."

90-second STAR. **S** An 18-month plan that would have consumed the full engineering effort. **T** Reach first value with less spend. **A** Reuse over 8 dev-weeks, partner backend as the shared chassis, confidence buffers, scope swaps instead of absorption. **R** Effort −66%; decomposition $2.85M + $1.52M = $4.4M against the record ~$5M.

Land: ~$5M cost avoidance (record), said once · **Pivot to NACF:** reuse over rebuild in a network program: the 8-week rule is an engineering-median threshold.

Do NOT say: avoidance and annual reduction as two results; the engineers and rate as the program's.

B4 · "Tell me about a time when you had to communicate a change in direction that you anticipated people would have concerns with. What did you do to understand the concerns and mitigate them?"

AIQB: Earn Trust Q1 **Earn Trust** FACET: DATA ANALYSIS

Open (first two sentences): "Operators would stay on the old screens two more quarters. I priced that and published it instead of hiding it."

90-second STAR. **S** A sequencing choice that delayed one group for the benefit of the whole. **T** Be transparent about who pays. **A** The baseline memo showed 20% of operator time still in the old app under the inherited path; I priced two more quarters for operators, published the schedule, and made the partner backend the chassis they later ride. **R** No hidden trade; operators' move got cheaper, not later.

Land: two quarters, priced and published · **Pivot to NACF:** a network change that burdens one node temporarily: price it, publish it, give the date it ends.

Do NOT say: that the delay was costless.

SAME STORY, THREE ANGLES — THREE CARDS, THREE OPENERS, THREE METRICS, THREE LPS

Data / analytical angle **Dive Deep**

Opener: "Three hundred thirty-nine and a half minutes and twenty-two hundred interactions per shipment — with those two numbers the roadmap debate became arithmetic."

Headline metric: 339.5 min × $0.45 ≈ $153; −25% vs −50%

- Price each path at the work-item grain.
- The 20% residue caps operator-first at half.
- Confidence buffers: 27.6 vs 20 weeks.
- Say "derived" on the $153.

Conflict / influence / backbone angle **Have Backbone; Disagree and Commit**

Opener: “It was my manager's plan. I read it to him alone, with numbers, and gave engineering two days to break it.”

Headline metric: two points argued; one adjusted

- Private first, then the room.
- His name on the flip.
- Reversal trigger written in advance.
- Never won on seniority.

Honest failure-and-learning angle **Are Right, A Lot**

Opener: “What I did not see was Asia: right after the April 2022 import-side launch, the review showed 21 seconds at P95 against 3.3 in the US.”

Headline metric: 21.19 s vs 3.3 s

- The plan sequenced by value and effort, not by the pilot's geography.
- The fix was infrastructure sequencing (see S12-A).
- The lesson imported into later plans: geography is a performance requirement.
- What held: the sequencing decision itself.

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS

"Five million — is that saved every year?"

Numeric answer. No. It is one-time avoidance, the record's signed figure. My decomposition is $2.85M engineering never spent + $1.52M pulled forward = $4.4M; the recurring run-rate is $1.52M a year, a separate modeled number on illustrative volume. They are never both claimed.

Say exactly: “It's avoidance — one time, said once. The run-rate underneath is a separate, smaller model; I never present the avoidance as annual.”

"Your twelve engineers — where did they come from?"

Numeric answer. My model: 12 × 18 months × 66% × $20,000 = $2,851,200. At 10–15 engineers and $15–25K the effort piece is $1.8M–$4.5M; with the pulled-forward piece the decomposition is $2.9M–$6.7M, and the record's ~$5M sits inside that range.

Say exactly: “Those are my modeled inputs — the record doesn't itemize the five million. Across ten to fifteen engineers it moves from about two to four and a half million; I'd firm it with Finance's rate.”

"Why is your plan 27.6 weeks when two 10-week modules is 20?"

Numeric answer. (10 × 1.0 + 10 × 1.4) × 1.15 = 27.6 — the 1.4 applies only to the low-confidence module, plus a 15% testing buffer; 38% over naive, and the buffer is not spread evenly.

Say exactly: “The buffer only goes where confidence is low — twenty-seven point six against twenty naive — so the extra eight weeks are the risky module, not padding.”

S12-A — Flexport — Why Asia waited 21 seconds: a P95 latency investigation that split one complaint into a static-content problem and a routing problem, then ran it as a dated, smoke-tested change plan NEW

LPs this story can serve here: Dive Deep (primary) · Customer Obsession · Bias for Action · Insist on the Highest Standards
Process family: Improve — root-cause investigation of a regional performance gap; change control for network and security changes

LEADERSHIP PRINCIPLES THIS STORY CARRIES — ONE-LINE PROOF SENTENCE EACH

Dive Deep The review said "Asia is slow"; the work was to find where the 21.19 seconds went — region split, static versus dynamic, and a China static-JS P95 of 5 s against 0.5 s in the US — before anyone bought a CDN.

Customer Obsession Asia was 45.3% of the 13.92 thousand page views in the window, so the slowest region was the largest region — the plan was ordered by where the partners actually were.

Bias for Action Reversible fixes went first — double CDN removed in China, WAF on globally — and the expensive one (CDN for the dynamic host) was deferred until the metrics said it was needed.

Insist on the Highest Standards Every WAF or CDN change ran a written pre-check, a post-check and a rollback-able DNS override — 32 smoke checks a change — and I will not claim a single-cause before-and-after that the record does not support.

Honesty label. This is an investigation story with a split of credit: the investigation document is the app team engineer's, with the network infrastructure owner running the CDN and WAF changes — *I did not write the root-cause doc or make the network changes*. What I tell as mine is the program side: the monthly review that surfaced the gap, the cut by region, the dated plan with owners, the change-control discipline and the insistence on a like-for-like measurement. **My seat** (my own workbook, Apple v11 B3, and the document): the investigation is authored by the app engineer, and the network-infrastructure owner made the CDN and DNS changes (the plan's owners are named in the document); I drove the follow-ups from the monthly review and kept the plan, the sequencing and the China-host smoke tests honest. I say "I drove the follow-ups", not "I fixed the CDN". **Before-and-after flag:** the investigation window (Apr 24 – May 10) and the review series differ in window and region definition, so the 81% figure I can compute is indicative only — I do not quote it as the result; the like-for-like record is the review series. The document's Asia table and its China-specific plan rows belong to one investigation, with China the sharpest tail; the later review series splits Asia (non-China) from China, so the 21.19 s and the later 4.0 s may not be the same population — I never subtract across them. Overlap: this story is also on the bench in another interviewer's packet.

WHAT THE RECORD SAYS (FROM THE INVESTIGATION DOCUMENT AND THE WEEKLY REVIEW SHEET; RECORD-FROM-DOCS)

Context. The Freight Forwarding App (FFA) launched its import-side app in April 2022 to 11 partners across 10 countries; through May, 48 of 53 import partners were migrated. The monthly review showed Asia countries with much higher latency than other regions. RECORD-FROM-DOCS

The numbers. Page-load P95 for Apr 24 – May 10 (Datadog view loading time, which covers static resources, the GraphQL request and the render): US 3.3 s on 2.19k views; Asia 21.19 s on 6.31k views; Others 4.45 s on 5.42k views. Static JavaScript P95: China 5 s against 500 ms in the US. RECORD-FROM-DOCS

Two named causes. (1) Static resources are served from a CDN host that performs poorly in China; (2) the dynamic host has no geo-based DNS or regional reverse proxy for Asia, so GraphQL requests cross the public internet instead of the data-center backbone. RECORD-FROM-DOCS

The plan. Eight rows, owners and ETAs: three security (WAF proposal, WAF for China, WAF globally — follow-ups to an incident) and five latency (remove the double CDN in China — done, ETA June 24; static-CDN proposal for China and Asia, July 15; tuning for China, July 30; tuning for Asia, August 15; CDN for the dynamic host globally — "decide based on the metrics", Q3 or later). A written change process: override DNS locally, verify resolution, smoke-test

internal single-sign-on and partner users, repeat on the China instance, change, then remove the override and re-test. RECORD-FROM-DOCS

The review series. The weekly review sheet carries page-load P95 overall and by region (weeks 33 to 52 and week 1) and a monthly view (April to September). The sheet's action items include adding GraphQL latency at P50, P90 and P95 by region (done October 11, 2022). RECORD-FROM-DOCS

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. We had launched the import-side freight-forwarder app in April 2022 and moved 48 of 53 import partners onto it by May. At the monthly review the latency chart had an outlier: Asia. **Task.** Find out whether it was one problem or several, and where the time was going, before anyone bought anything. **Action.** I cut the 13.92 thousand views by region over the 17-day window: Asia was 45% of the views and waited 21.19 seconds at the 95th percentile against 3.3 in the US — 6.4 times. Then I asked where the time goes: static JavaScript took 5 seconds in China against half a second in the US, and the dynamic requests from Asia went over the public internet because there was no regional edge. Two causes, two owners. I ordered the plan by reversibility — remove the double CDN, turn on the firewall — held the expensive global CDN until the metrics asked for it, and put every network change behind a written DNS-override and smoke-test checklist. **Result.** Primary metric: the Asia-to-US gap of 6.42× — and in the review series that followed, Asia read 4.0 seconds against 4.09 in North America by the last week of the year, with overall monthly P95 down from 8.39 to 4.68 seconds. I tell that as a gap that closed, not as a single-cause saving.

SAFE-SAY — TWO SENTENCES TO SAY EXACTLY

Most attackable number. “Asia waited about twenty-one seconds at the ninety-fifth percentile against about three and a third in the US — roughly six and a half times — over a seventeen-day window of about fourteen thousand page views.”

“What's your source for that?” “It is the latency document's own table; the six-point-four is my division of its two printed figures, and the later four seconds against four-oh-nine is from the monthly review series — I describe it as a gap that closed, not a single-cause saving.”

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — Flexport's freight-forwarder app was in its first months: the import-side app live to 11 partners in 10 countries in April 2022, then 48 of 53 import partners (about 90%) by the end of May. The monthly review flagged that Asian users saw far higher page-load latency than anyone else — 21.19 seconds at P95 against 3.3 in the US on the same two-and-a-half-week window — and Asia was the single largest slice of traffic. The risk: a freight partner who waits twenty seconds for a shipment page goes back to email, and the cost-to-serve case for the whole migration depends on partners using the app.

T — Turn "Asia is slow" into named causes with owners and a dated plan, sequence the changes so the cheap and reversible ones run first, keep the production network and security changes safe, and prove the improvement with a measurement that can be trusted.

Baselines on the table: Page-load P95: US 3.3 s · Asia 21.19 s · Others 4.45 s · views 2.19k / 6.31k / 5.42k · window Apr 24 – May 10 (17 days) · static JS P95 China 5 s vs US 0.5 s · 48 of 53 partners migrated · 8 plan rows (3 security, 5 latency).

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery** — cut P95 and views by region over the window; read the resource-level data; mapped the request path for static content and for GraphQL; wrote the two-cause hypothesis and what each predicts. *Exit bar:* a region table with views, and a named hypothesis per cause.
- **Plan & Design** — sequenced eight rows by reversibility and dependency: security first where an incident was open, then the double-CDN removal, then proposals, then tuning; wrote the decision rule to defer the global CDN until the

metrics asked for it; listed the open measurement question — how to test the China CDN in a consistent, reproducible way. *Exit bar:* owners and ETAs on every row; one conditional row with its trigger.

- **Build & Test** — the change process: override DNS locally, verify resolution, smoke-test internal single-sign-on and partner log-in, workview, log-out and re-log-in, repeat on the China instance; infra performs the change; then remove the override, clear the cache and test again. *Exit bar:* 32 checks per change (16 before, 16 after).
- **Cutover & Go-Live** — WAF on for China and globally and the double CDN removed in China, each behind the checklist, ETAs June 24 – June 30; static-asset tuning for China and Asia dated July 30 and August 15. *Exit bar:* four of eight rows marked done in the document; dated owners on the rest.
- **Hypercare / Close** — the monthly and weekly reviews carry page-load P95 by region; the action item to add P50 / P90 / P95 GraphQL latency by region closed October 11, 2022; the week-47 spike was triaged against the region split rather than assumed to be the network. *Exit bar:* a regional series the review reads every week.

Influence and ownership. Mine (as I would tell it): the review that surfaced the gap, the region cut, the sequencing rule, the change checklist discipline and the insistence on a like-for-like measure. Not mine: the root-cause write-up, the CDN and WAF changes, the security sign-offs and the app optimizations — the app engineer and the network-infra owner own those, with the security reviewer signing the firewall proposal.

> **Designed the process; others own it now.** The change process, the region cut in the weekly review and the P50 / P90 / P95 action item live in the document and the sheet, not in my head. **Trade-off put to leadership.** Buy a global CDN now (certain cost, unknown benefit) against two cheaper reversible fixes first and a metrics trigger — the schedule risk was that the global CDN row slipped to Q3 or later.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY (RECORD VS MODELED LABELED)

- **$** — No dollar exists in the record. I model exposure, labeled illustrative: Asia's 45.3% of views against the S12 run-rate ≈ $0.69M a year (modeled upper bound, not savings); the direct tail time is ≈ $1.6K a year, which is why the case is adoption, not seconds.
- **#** — Asia 21.19 s vs US 3.3 s = 6.42× on 6.31k of 13.92k views; 32 smoke checks per change; 8 plan rows, 4 marked done.
- **%** — overall page-load P95, review monthly series, April to September: 8.39 s → 4.68 s, −44.2% (record-from-docs); Asia (non-China) 5.5 → 4.0 s, −27.3%, North America 5.62 → 4.09 s, −27.2% over weeks 39 to 52 (record-from-docs, my arithmetic).
- **Time** — plan span June 24 → August 15 = 52 days; the P50 / P90 / P95 by-region action item closed October 11, 2022.
- **Customer** — Asia partners were the largest slice of views; by the last week of the year the review series put Asia (non-China) within 2% of North America, and China at 1.57× North America.
- **Quality** — zero unreviewed network changes — every WAF or CDN change had its pre-check and post-check — and a before-and-after claim limited to what the like-for-like series supports.

L6 LEVEL EVIDENCE — this story against the Amazon L6 functional rubric; every line is this story's record or labeled model

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	One complaint, no known cause. The work was to split it into two testable causes (static content path, dynamic routing path) and to name what would disprove each.
Scope & influence	Engineering, network infrastructure and security each owned a piece; the plan was a one-page sequence with owners and dates that none of them could do alone.
Execution trade-off + mechanism others now own	Deferred the global CDN on a metrics trigger — a deliberate schedule risk. The mechanism others own: the change checklist, the by-region series and the P50 / P90 / P95 view.
Impact (long-term)	The review series that followed shows the Asia gap gone by week 39 and China as the remaining outlier — a clear next investigation instead of a vague complaint.
Process improvement (standard work institutionalized)	DNS-override + smoke-test + rollback as the standard for WAF and CDN changes; regional percentiles on the weekly review.
Complexity & consensus	App team, network infrastructure and security with different incentives — a written plan with a conditional row resolved the "just buy the CDN" push without a standoff.
Root cause at scale	The 6.42× gap was a path problem, not an app problem — week 47 proved it from the other side, when North America spiked 2.09× as well.

FIVE FACETS AT A GLANCE — the labeled structure the probing section below follows

1 · Data analysis	P95 and views by region; Asia 45.3% of views; static JS 10× slower in China; P95 versus P99 sample sizes (63 observations against 22); the review series by region and week.
2 · Solution design	Static path versus dynamic path; six options weighed; reversible-first sequence; metrics trigger for the global CDN.
3 · Math & data logic	Gap ratios 6.42× and 1.35×; tail views 315.5; 52-day plan; 32 checks; −44.2% overall; Asia / NA 0.98×; exposure $0.69M (illustrative).
4 · Implementation	Eight plan rows with owners and ETAs; the DNS-override change process; WAF first, double CDN removed next; China tuning, then Asia.
5 · Probe questions	Seven numeric probes plus three trap drills: the 81% temptation, P95s that do not add, P99 on thin data.

PROBING — FIVE FACETS, THEN THE FULL DRILL

Facet 1 — Data analysis (what data, grain, joins, cuts, what it revealed)

What I read. Three sources, all RECORD-FROM-DOCS: (1) the investigation document's region table — page-load P95 and views for Apr 24 – May 10; (2) its resource-level cut — static JS P95 China 5 s vs US 0.5 s; (3) the weekly and monthly review sheet by region (weeks 33–52, week 1; April–September monthly). I added the shares, the ratios and the tail-sample arithmetic.

REGION	PAGE-LOAD P95	VIEWS	% OF VIEWS	VS US	TAIL VIEWS (5%)
US	3.30 s	2,190	15.7%	1.00×	109.5
Asia	21.19 s	6,310	45.3%	6.42×	315.5
Others	4.45 s	5,420	38.9%	1.35×	271.0
Total	—	13,920	100%	—	696

What it revealed. (1) *The largest region was the slowest:* Asia carried 45.3% of views at 6.42× the US P95. (2) *Two paths, two causes:* static JS in China at 10× the US P95; dynamic GraphQL from Asia over the public internet with no regional edge. (3) *Why P95 and not P99:* in 17 days Asia has 6,310 views, so P99 rests on 63 observations and the US P99 on 22 — P95 rests on 316 and 110, which is stable enough to steer by. (4) *P95s do*

not add: the 5 s static-JS P95 is not 5 s of the 21.19 s page-load P95; the right test is to re-measure page load after every change. (5) *The later review series is a different population* — it splits Asia (non-China) from China — so I never subtract across the two sources. (6) *Week 47:* North America went from 4.52 to 9.44 s (2.09×) in the same week Asia went from 7.16 to 16.4 s (2.29×) while China fell — an application-wide regression, not a regional network one. The review sheet's own 12/12 callout explains a GraphQL-latency spike for the Core and Client Apps as a change in the metrics code that made the dashboard numbers wrong, fixed retroactively — a measurement error, not a network one; the October regression is a separate cause (work_view 2.0 un-optimized queries, action item 11). I do not quote week 47 as an Asia result.

Facet 2 — Solution design (options considered, chosen design, why)

DESIGN QUESTION	OPTIONS WEIGHED	CHOSEN	WHY (RECORD UNLESS MARKED)
Static content in China	Increase CDN cache time · remove the double CDN (direct connect to the object store) · replicate assets into China / Asia (needs security approval) · another CDN or a global accelerator	Remove the double CDN first; replicate assets after a proposal and sign-off	Removal is reversible and needs no new vendor; replication needs a security approval first.
Dynamic requests from Asia	CDN for the dynamic host · geo-based DNS with a regional reverse proxy over the backbone · leave it	Regional edge proxy via geo DNS is the target; global CDN deferred on a metrics trigger	The document's own wording: finish the other items, then decide on the metrics.
Security vs latency order	Latency first · WAF first	WAF proposal and rollout first for China and globally	An open incident follow-up; the WAF and the CDN share a change path, so one checklist covers both.
How to measure the China CDN	Real-user views only · synthetic probes · both	Open question in the document	Raised as "consistent and reproducible"; resolved partly by adding P50 / P90 / P95 by region to the review (done October 11, 2022) VERIFY-WITH-RAJESH · V4
Priority	By worst P95 · by traffic share	By traffic share, reversibility and dependency	Asia = 45.3% of views; China is the sharpest tail but a smaller share.

Facet 3 — Math & data logic (four tables: Before · Fix substituted · After · Dollars)

Table 1 — Before: the problem in numbers

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Views in the window	`2.19k + 6.31k + 5.42k = 13.92k; Apr 24–30 = 7 days + May 1–10 = 10 days = 17 days`	record-from-docs inputs	13.92k views over 17 days
2	Asia's share of views	`6.31 / 13.92 = 45.3%; per day 6,310 / 17 = 371 of 13,920 / 17 = 819`	my arithmetic on record inputs	45.3% · 371 of 819 a day
3	P95 gaps	`21.19 / 3.30 = 6.42×; 4.45 / 3.30 = 1.35×; 21.19 / 4.45 = 4.76×`	my arithmetic on record inputs	Asia 6.42× US
4	Static JS	`China P95 5 s / US P95 0.5 s = 10×`	record-from-docs inputs	10×
5	Tail sample: why P95	`5% × 6,310 = 315.5 Asia views above P95; 1% × 6,310 = 63.1 above P99; US 1% × 2,190 = 21.9`	my arithmetic; the document gives no P99	P95 on 316 views; P99 on 63 (US 22)

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
6	Adoption context	`48 / 53 import partners migrated — about 90% (the document prints 90.5%)`	record-from-docs inputs; rounding mine	about 90%

Table 2 — The fix: the plan, the change control and the measurement rule, values substituted

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Plan composition	`3 security rows + 5 latency rows = 8; marked done: 3 security + 1 latency = 4`	record-from-docs plan rows; count mine	8 rows, 4 done
2	Plan span	`June 24 → August 15: 6 days left in June + 31 in July + 15 in August = 52 days`	record-from-docs ETAs; arithmetic mine	52 days
3	Smoke checks per change	`2 user types (internal SSO, partner) × 4 steps (log-in, workview, log-out, re-log-in) × 2 instances (main, China) = 16; before + after = 16 + 16 = 32`	record-from-docs change process; count mine	32 checks per change
4	Decision rule for the global CDN	`do the reversible items first; re-read the regional P95; buy the global CDN only if Asia and China stay above the others after tuning`	record-from-docs wording; rule stated as I would run it	a trigger, not a date
5	Weekly sample for one P95 read	`6,310 / 17 × 7 = 2,598 Asia views a week; 5% = 130 tail views`	my arithmetic at the window rate; volume has grown since	≈ 130 tail views a week

Table 3 — After: the review series (record-from-docs), before → after

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Overall P95, monthly	`April 8.39 s → September 4.68 s: (8.39 − 4.68) / 8.39 = 44.2%`	record-from-docs; arithmetic mine	−44.2%
2	Asia, weekly	`week 39 5.5 s → week 52 4.0 s: (5.5 − 4.0) / 5.5 = 27.3%`	record-from-docs (Asia non-China); arithmetic mine	−27.3%
3	North America, weekly	`week 39 5.62 s → week 52 4.09 s: (5.62 − 4.09) / 5.62 = 27.2%`	record-from-docs; arithmetic mine	−27.2%
4	China, weekly	`week 39 9.9 s → week 52 6.43 s: (9.9 − 6.43) / 9.9 = 35.1%`	record-from-docs; arithmetic mine	−35.1%
5	Gap to North America	`Asia 5.5 / 5.62 = 0.98× (week 39); 4.0 / 4.09 = 0.98× (week 52); China 6.43 / 4.09 = 1.57×`	my arithmetic on record-from-docs series	Asia at parity; China 1.57×
6	Week 47 spike	`NA 4.52 → 9.44 s = 2.09×; Asia 7.16 → 16.4 s = 2.29×; China 13.8 → 9.36 s (fell)`	record-from-docs; arithmetic mine	not regional
7	Indicative only — do not quote	`(21.19 − 4.0) / 21.19 = 81.1% mixes a 17-day investigation window with a week-52 review figure and possibly different region definitions`	my arithmetic; NOT a result	indicative

Table 4 — The dollars: none in the record; two labeled models

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Record dollars	`the investigation prices nothing; the plan rows carry no cost`	record-from-docs	$0 in the record
2	Excess seconds per tail view	`21.19 − 4.0 = 17.19 s (P95 to P95; indicative)`	illustrative: uses the indicative pair	17.19 s
3	Tail hours in the window	`315.5 views × 17.19 s = 5,423 s; 5,423 / 3,600 = 1.51 h`	illustrative arithmetic	1.51 h

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
4	Direct tail time per year	`1.5065 h × 365 / 17 = 32.3 h; 32.3 h × $50 = $1,617`	illustrative: $50 an hour assumed	≈ $1.6K / yr
5	Exposure on the S12 run-rate	`$76 × 20,000 = $1,520,000; × 6.31 / 13.92 = $689,023`	modeled on a modeled run-rate (volume illustrative); views are not shipments — an upper-bound exposure, not savings	≈ $0.69M / yr at risk

Facet 4 — Implementation (phases, owners, rollout, cutover, controls, risks)

PLAN ROW (RECORD)	REGION	ETA	OWNER	STATUS IN THE RECORD
WAF proposal for FF App with the process	All	06/30	app engineer / network infra	done
WAF for the main host in China (incident follow-up)	CN	06/30	network infra / app engineer	done
WAF globally (incident follow-up)	All	06/30	network infra / app engineer	done
Remove the double CDN for static content in China — direct connect to the object store	CN	06/24	network infra	done
Proposal to resolve static CDN performance in China and Asia	CN, Asia	07/15	app engineer + network infra	open
Performance tuning for static content — China	CN	07/30	network infra / app engineer	open; depends on proposal
Performance tuning for static content — Asia	Asia	08/15	network infra / app engineer	open; depends on proposal
CDN for the dynamic host globally	All	Q3 or later	network infra	conditional on the metrics

Change process (record) and my controls. Before: local DNS override, verify resolution, smoke test for internal and partner users, repeat on the China instance. Change: network infra only. After: remove the override on both hosts, clear the cache, re-test. **Risks named:** security approval before replicating assets in China; no consistent way yet to benchmark the China CDN; dependency of the tuning rows on the proposal. **Lean / Kaizen mapping.** Going to see where the seconds are is genchi genbutsu; the two causes are root-cause analysis (5 Whys by path); the DNS-override checklist is poka-yoke and standard work; each change followed by a re-measure is PDCA; removing the double CDN is eliminating a waste step; every tail view is waiting waste.

Facet 5 — Probe questions (hardest follow-ups, numeric answers)

> **Why P95 and not the average or P99?**
>
> The average hides the tail users feel and P99 is too thin: in 17 days Asia has 6,310 views, so P99 rests on 63 observations and the US on 22, while P95 rests on 316 and 110. P95 is stable enough to steer by and sensitive enough to show 21.19 seconds against 3.3.

> **How do you know it was a network problem and not the app?**
>
> Two checks. Resource-level: static JS P95 was 5 s in China against 0.5 s in the US. And by region over time: in week 47 North America doubled (4.52 → 9.44, 2.09×) with Asia (7.16 → 16.4, 2.29×) while China fell — that is an application regression, a different problem, which I did not blame on the network.

Did the plan actually close the gap?

The like-for-like review series says the Asia (non-China) gap to North America was closed by week 39 — 5.5 against 5.62 — and stayed there at week 52 (4.0 against 4.09); China remained at 1.57×. What I cannot show is which change moved it between May and September — the record does not attribute.

Why defer the global CDN?

Because two reversible changes were ahead of it and the document itself said to decide on the metrics. A global CDN is a certain cost and an unknown benefit; the right time to buy it is when the regional P95 stays above the others after tuning.

What did the investigation cost and save in dollars?

The record prices nothing. I model it as adoption protection: Asia was 45.3% of views, and 45.3% of the S12 run-rate is ≈ $0.69M a year of exposure — an upper bound, not savings. The direct tail time is about $1.6K a year, which is why the argument was never seconds times dollars.

What would you do differently?

Start with P50, P90 and P95 by region from day one — the action item to add them closed only on October 11, 2022 — and decide up front how to benchmark the China CDN consistently, which the document listed as an open question.

Your 81% — where is it from?

It is (21.19 − 4.0) / 21.19, which mixes the 17-day investigation window with a week-52 review figure — an indicative number, not a result. The like-for-like numbers are −27.3% for Asia over weeks 39 to 52 and −44.2% overall from April to September.

BUSINESS IMPACT MODEL — KPI TREE

```
Asia partners can use the app without waiting: gap to the home region closed, tail visible, changes safe
+- Gap: Asia 21.19 s vs US 3.30 s = 6.42x on 45.3% of views (record)
|    +- static path: China JS 5 s vs 0.5 s = 10x -> remove double CDN (done) -> proposal -> tuning
|    +- dynamic path: no geo DNS / regional proxy -> GraphQL over the public internet -> edge proxy (CDN
deferred on metrics)
+- Result (review series, record): overall P95 8.39 -> 4.68 s (-44.2%); Asia 5.5 -> 4.0 s vs NA 5.62 ->
4.09 s; China 6.43 s = 1.57x NA
+- Control: 32 smoke checks per WAF / CDN change; P50 / P90 / P95 by region on the weekly review
+- $ (illustrative / modeled): tail time ~ $1.6K/yr; exposure ~ $0.69M/yr (upper bound, not savings)
(loop)  complaint -> split by region -> split by path -> reversible fix first -> re-measure -> next fix
```

SOLUTION FLOW

```
monthly review: Asia is the outlier
   -> cut by region: views, P95  (17 days; Asia 45.3% of views, 6.42x US)
   -> cut by path: static (CDN) vs dynamic (GraphQL route)
   -> two causes, two owners, one dated plan (8 rows)
   -> every change: DNS override -> smoke test x16 -> change -> remove override -> smoke test x16
   -> re-read regional P95 -> decide: next tuning row, or the conditional CDN row
```

SENSITIVITY — LOW / BASE / HIGH

ASIA SHARE OF VIEWS (ILLUSTRATIVE RANGE)	EXPOSURE ON THE S12 RUN-RATE	READ
30%	$1,520,000 × 30% = $456,000	≈ $456K a year at risk
45.3% (observed)	$1,520,000 × 45.3% = $689,023	≈ $689K a year at risk
60%	$1,520,000 × 60% = $912,000	≈ $912K a year at risk

Both the $76 × 20,000 run-rate and the view-to-shipment mapping are modeled; the three rows are a range of the share, not a forecast. None of it is claimed as savings.

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

The record number here is a gap, not a dollar. At the monthly review Asia showed a twenty-one second page-load P95 against three-point-three in the US — six and a half times — on forty-five percent of the views. I split it into two paths: static content in China, where the JavaScript took five seconds against half a second, and dynamic requests that crossed the public internet with no regional edge. We sequenced the cheap, reversible changes first, put every network change behind a thirty-two-check smoke test, and held the expensive global CDN until the metrics asked for it. In the review series that followed, overall monthly P95 fell from eight-point-four to four-point-seven seconds, and Asia read four seconds against four-point-one in North America by the last week of the year. I tell that as a gap that closed, not as one change that saved something — the record doesn't attribute it, and any dollars I attach, about seven-tenths of a million of exposure, are modeled and not claimed.

IF CHALLENGED — THE FULL ANSWERS

"You are claiming credit for an infrastructure fix you didn't build."

No. The root-cause document and the CDN and WAF changes were the app engineer's and the network-infra owner's. What I own is the region cut, the sequence, the change checklist discipline and the measurement honesty — and I say so in the first sentence.

"Latency is a technical metric. Where is the business?"

Asia was 45.3% of views, and the cost-to-serve case for the whole migration depends on partners using the app. The exposure on the S12 run-rate is ≈ $0.69M a year as a modeled upper bound; the direct tail time is ≈ $1.6K — which is the point: the case is adoption.

"Why not just throw a global CDN at it?"

Because the reversible items came first and the document tied the global CDN to the metrics. A CDN would add cost and ops without telling us which hop is slow.

20-SECOND VERSION AND NACF BRIDGE

20-SECOND VERSION

At Flexport the monthly review showed Asian users waiting 21 seconds at P95 on the freight-forwarder app — 6.4 times the US, on 45% of the views. I split it into a static-content problem and a routing problem, sequenced the reversible fixes first behind a 32-check smoke test, and the review series later showed Asia level with North America.

NACF BRIDGE — ONE SENTENCE

A geo-routed edge near the user with a backbone between sites is the cross-dock placement idea in software: put a node near demand, run the linehaul between hubs, and measure the tail — a P95 on inbound transit or dock wait, not the average, is what sizes appointment buffers and capacity.

BEHAVIORAL PACK — FOUR QUESTIONS THIS STORY ANSWERS, EACH A SEPARATE 90-SECOND STAR FROM A DIFFERENT FACET

B1 · "Walk me through a big problem or issue in your organization that you helped to solve. How did you become aware of it? What information did you gather? What information was missing and how did you fill the gaps?" AIQB: Dive Deep Q4 **Dive Deep** FACET: DATA ANALYSIS

Open (first two sentences): "At a monthly review, Asia showed a twenty-one second page-load P95 against three seconds in the US. The average would have hidden that; I split the tail by region and then by request path."

90-second STAR. S Freight-forwarder app launched in April 2022, 48 of 53 partners on it by May; one region far slower than the rest. **T** Find out where the time goes before anyone buys a fix. **A** I cut 13.92 thousand views by region — Asia 45.3% of views at 6.42× the US P95 — then by path: static JS P95 5 s in China against 0.5 s in the US, and GraphQL from Asia over the public internet with no regional edge. I checked sample sizes — P99 would have rested on 63 observations — and used P95. **R** Two named causes with owners, a dated eight-row plan, and a regional series on the weekly review.

Land: 6.42× on 45.3% of views · **Pivot to NACF:** inbound transit-time by origin lane: the tail by region, not the average, is what sizes buffers and dock-appointment slack.

Do NOT say: that I found the root cause alone, or "I cut Asia latency 81%".

B2 · "Tell me about a time when you evaluated the customer experience of your product or service. What did you do? What was the result?" AIQB: Customer Obsession Q5 **Customer Obsession** FACET: SOLUTION DESIGN

Open (first two sentences): "The slowest region was also the largest: Asia was forty-five percent of the views. So the plan was ordered by where the partners actually were, not by what was easiest to tune."

90-second STAR. S Freight partners across 10 countries using the new app; the review showed one region waiting far longer. **T** Prioritize the work by who is hurt most. **A** I weighed six options — cache time, double-CDN removal, asset replication, regional edge, global CDN, an accelerator — and ordered them by traffic share, reversibility and dependency; the global CDN waited on a metrics trigger. **R** A plan where the first changes were the reversible ones, and by week 39 the review series put Asia (non-China) within 2% of North America.

Land: 45.3% of views · **Pivot to NACF:** siting a node: weight the lanes by volume first, then the tail; the largest flow decides the sequence.

Do NOT say: any dollar figure as savings, or customer complaints that the record does not document — the document says the slowness was noticed in the monthly business review.

B3 · "Give me an example of a calculated risk that you have taken where speed was critical. What was the situation and how did you handle it? What steps did you take to mitigate the risk? What was the outcome?" AIQB: Bias for Action Q1 **Bias for Action** FACET: IMPLEMENTATION

Open (first two sentences): "We started with the changes that could be undone — removing a double CDN, turning on the firewall — and held the expensive global CDN until the metrics asked for it."

90-second STAR. S A latency gap and an open security incident follow-up on the same network path. **T** Move fast on the reversible, slow on the expensive. **A** I sequenced eight plan rows with owners and ETAs from June 24 to August 15 — 52 days — put the firewall and the double-CDN removal first, and wrote the DNS-override smoke-test routine so each change could be verified and backed out. **R** Four of eight rows marked done in the document by June 30; the conditional row stayed conditional.

Land: 52-day plan; 4 of 8 rows done · **Pivot to NACF:** peak prep: do the reversible changes first and buy capacity last — the same logic as flexing labor before adding a door.

Do NOT say: that every row finished on time — only four were marked done; the tuning rows had ETAs, not results.

B4 · "Describe a time when you refused to compromise your standards around quality/customer service, etc. Who was your customer? What was the result?" AIQB: Highest Standards Q1 **Insist on the Highest Standards**

FACET: PROBE QUESTIONS

Open (first two sentences): "Every WAF or CDN change ran thirty-two smoke checks, and I refused to quote a before-and-after the data couldn't support — including a flattering eighty-one percent I could have computed."

90-second STAR. S Production network changes in two regions, plus a tempting headline number. **T** Keep production safe and the claims honest. **A** The change process: DNS override, resolution check, internal and partner log-in, workview, log-out and re-log-in, repeated on the China instance, before and after. For the result I used the like-for-like review series, not the investigation window against a week-52 figure. **R** No unreviewed network change; claims limited to −44.2% overall and Asia 5.5 → 4.0 s over weeks 39 to 52.

Land: 32 checks per change; 81.1% not quoted · **Pivot to NACF:** a standard pre-check and post-check on every dock or yard change, and a rule not to compare windows that are not like for like.

Do NOT say: that the 81% is a result; that I attributed the drop to one change.

SAME STORY, THREE ANGLES — THREE CARDS, THREE OPENERS, THREE METRICS, THREE LPS

Data / analytical angle **Dive Deep**

Opener: "The average looked fine; the ninety-fifth percentile in Asia was twenty-one seconds, on forty-five percent of the views."

Headline metric: 6.42× on 6.31k of 13.92k views

- Region cut first; path cut second (static vs dynamic).
- Sample-size logic: P99 on 63 observations vs 22 in the US; P95 on 316 / 110.
- P95s do not add: 5 s of JS is not 5 s of 21.19.
- Week 47: NA 2.09×, Asia 2.29× — application, not network.

Conflict / influence / backbone angle **Have Backbone; Disagree and Commit**

Opener: "The loud ask was "just turn on a global CDN"; I held it until the metrics asked for it, and that cost us a schedule row."

Headline metric: one conditional row (Q3 or later); 4 of 8 rows done

- Network infra, the app team and security each owned a piece; none could close it alone.
- The plan's conditional row resolved the push without a standoff.
- Security approval before replicating assets in China — I kept that gate.
- My seat: I drove the follow-ups and kept the plan and the smoke-test checklist honest; the app engineer and network owner made the changes.

Honest failure-and-learning angle **Learn and Be Curious**

Opener: "We measured P95 only; P50 and P90 by region did not exist until October, and we never had a like-for-like before-and-after."

Headline metric: window-mismatched 81.1% — not quoted

- The action item to add P50 / P90 / P95 by region closed on October 11, 2022.
- The China CDN had no consistent way to be benchmarked — an open question in the document.
- What I would do differently: baseline by region on the weekly series from day one.
- What held: no unreviewed change and no overclaimed result.

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS

"So you cut Asia latency by 81%."

Numeric answer. No. (21.19 − 4.0) / 21.19 = 81.1% subtracts a 17-day investigation figure from a week-52 review figure that may not be the same region population. Like-for-like: Asia (non-China) 5.5 → 4.0 s = −27.3% over weeks 39 to 52; overall monthly 8.39 → 4.68 s = −44.2%.

Say exactly: “I wouldn't quote eighty-one percent — it compares two different windows. The like-for-like review series shows overall P95 down forty-four percent from April to September, and Asia level with North America by week 39.”

"Static JS was 5 seconds of your 21 — so fixing it saves 5 seconds?"

Numeric answer. No. A P95 of one resource is not a slice of a page-load P95, and P95s do not add. The 5 s China JS P95 against 0.5 s in the US (10×) points at the path; the number to steer by is the page-load P95, re-measured after each change.

Say exactly: “Percentiles don't add — five seconds at P95 for one resource isn't five seconds off the page. I re-measured page-load P95 after each change instead.”

"Why P95? Why not P99?"

Numeric answer. Sample size. In the 17-day window Asia had 6,310 views, so P99 rests on 1% × 6,310 = 63.1 observations and the US on 21.9; P95 rests on 315.5 and 109.5. At roughly 2,600 Asia views a week, a weekly P95 still has about 130 tail views.

Say exactly: “In seventeen days the US had about twenty-two views past its P99 — too thin to steer by. P95 had over a hundred in the US and over three hundred in Asia.”

S16-A — Flexport — The data model under the Monday review: a container-week grain, a ticket-to-container bridge, a 1% parity gate and a sync-drop alarm that turned four hand-stitched systems into one Snowflake pipeline NEW

LPs this story can serve here: Dive Deep (primary) · Invent and Simplify · Frugality · Insist on the Highest Standards
Process family: Improve — data pipeline and reconciliation design under an operating metric; build-vs-bridge and cutover gating

LEADERSHIP PRINCIPLES THIS STORY CARRIES — ONE-LINE PROOF SENTENCE EACH

Dive Deep The cost-to-serve ratio only works if tickets and containers are counted at the same grain; a join at the wrong grain would have made it look 44.4% better than it was (illustrative), so the grain was fixed before the pipeline.

Invent and Simplify A ticket-to-container cross-reference table shipped the join now, while the real key was pushed upstream to Support — ship with the bridge, fix the source — and seven frozen metrics replaced a pile of ad-hoc pulls.

Frugality The status quo was priced in the BRD (over $100K a year, priced not saved) so the infrastructure team could prioritize the build themselves; scope stayed at seven metrics and the existing BI tool — no new system bought.

Insist on the Highest Standards Nothing switched until every frozen metric matched the manual pull within 1% for consecutive weeks, every mismatch explained by cause, and a failed feed raised an alert instead of silence.

Honesty label. I wrote the business requirements document and owned the acceptance gate, the parallel-run procedure and the cutover call; *the infrastructure team built the pipeline* — I did not lay pipe, I made the pipe buildable (Apple A3). The ">$100K a year" is a **priced baseline** — priced, not claimed as savings: the BRD's own arithmetic is $103,680 (30 → 6 hours a week across two weekly reviews at an assumed $90 an hour) and my split of it into hours and decision risk is a model. The BRD names **no table or column** — it names the Zendesk Ticket ID, the Crux Container Number, Flexport core data and Looker SQL Runner views — so I describe the join, the grain and the artifacts, not a production schema; the container-week grain is my design logic, anchored to the weekly-stock grain the review already used (Apple A2). **Four systems:** the BRD names the ticket system, the Crux container pull (by hand, in Google Sheets) and core data; Apple A3's whiteboard lists ticketing, scraper registry, product-event DB and CRM — say "four systems" and name the ticket system and the container pull with confidence. **Overlap:** the failure angle here is the data-access security review (Apple G3), told as the one miss it was; the data-model, grain and reconciliation angle is this story's own.

WHAT THE RECORD SAYS (FROM THE BUSINESS REQUIREMENTS DOCUMENT AND THE PROGRAM NOTES; RECORD-FROM-DOCS)

Problem. Operator intervention for Shipment Visibility is managed in the ticketing system: a ticket is created when the visibility service fails to start tracking a submitted container automatically, and Data Services closes it. To track key metrics automatically, ticket data must be joined to container numbers from the visibility vendor's data, and then to core shipment data. RECORD-FROM-DOCS

As-is. Manual pulls from the ticketing system matched to a manual pull of containers into spreadsheets: 1.5–2 hours on average to produce one week-over-week snapshot of seven metrics (coverage automated, coverage with human input, tickets generated, tickets per active container, 4PL % within SLA, 3PL % within SLA, and the 4PL-vs-3PL delta). RECORD-FROM-DOCS

Requirements. BR-1 customer data protected; BR-2 interoperates with other capabilities; BR-3 feed daily, preferably hourly; BR-4 an alert to internal support users when the feed fails. Objectives: automated reporting through the BI tool's SQL runner; easy joins to core data. RECORD-FROM-DOCS

The pricing in the document. "On Average 3 resources are spending 5 hrs per week for 2 WBR's" at an *assumed* $90 an hour — printed as a $10,880 monthly cost amounting to $129,600 a year; reduced to 1 hr a week, $25,920; "Savings here would be $103,680 a year" (BRD p1–2; 30 → 6 hours a week). The printed monthly figure does not match its own annual (3 × 5 × 2 × 4 × $90 = $10,800). RECORD-FROM-DOCS **Say:** "over $100K a year — the BRD

priced it at $103,680 on thirty hours a week at an assumed ninety dollars an hour; my split into hours and decision risk is a model; priced, not a claimed saving."

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. The Monday review ran on four systems that did not talk, stitched together in spreadsheets by me — system accuracy 60%, 1.5 to 2 hours a snapshot, and tickets that carried no container number, so the program's cost-to-serve could not be computed from the data. **Task.** Write the requirements and the acceptance test for a pipeline that produces the same seven numbers without me. **Action.** I fixed the grain first — container by week, with tickets and containers counted at the same grain, because a join at ticket grain would have made cost-to-serve look about 44% better than it was. I shipped a ticket-to-container cross-reference table so the join could go live and pushed a real container ID upstream to Support. I priced the status quo in the BRD so the infrastructure team could prioritize the build, then set the gate: every frozen metric within 1% of the manual pull for consecutive weeks, mismatches explained by cause — mostly late tickets on the manual side — and an alert whenever the feed fails. **Result.** Primary metric: system accuracy 60% to 90% on one pipeline instead of four systems — and the first automated catch was a ticket-sync drop of about 4% that nobody could have seen by hand. The dollar I carry is a price in the BRD — over $100K a year, $103,680 on its own arithmetic — priced, not a saving.

SAFE-SAY — TWO SENTENCES TO SAY EXACTLY

Most attackable number. “The review was priced at over a hundred thousand dollars a year — the requirements document works it to a hundred and three thousand, six hundred and eighty on thirty hours a week at an assumed ninety dollars an hour — and that is a price, not a saving I claim.”

“What's your source for that?” “It is my own requirements document; the arithmetic and its monthly typo are printed on the page, my split into hours and decision risk is a model, and the accuracy, the parity gate and the four-percent catch are in my interview workbook.”

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — The program's weekly review needed seven operating metrics, and two of them — tickets generated and tickets per active container — required joining the support ticketing system to container data. The tickets did not carry a container ID. So the numbers were assembled each Monday by hand from four systems into spreadsheets: system accuracy 60%, one person able to produce them, and silent data loss nobody could see. A VP was steering the program by a number that only one person could produce.

T — Define the data contract and the acceptance test: one grain, a join that survives missing keys, definitions in code, a reconciliation gate to cut over, and a failure alert — and get the infrastructure team to build it by showing them the price of the status quo.

Baselines on the table: Four systems · 1 person · system accuracy 60% · 1.5–2 h per weekly snapshot (BRD) · 7 frozen metrics · tickets with no container ID · no failure alarm · priced baseline: BRD $129,600 a year → $103,680 difference (30 → 6 h/wk at an assumed $90/h), over $100K priced, not saved (my model: $100,360).

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery** — documented the as-is — which systems, which pulls, which join — named the key gap (tickets without a container ID), froze seven metric definitions with their owners, and priced the status quo in the BRD (over $100K a year) so the infrastructure team could prioritize the build themselves. *Exit bar:* infra prioritizes the build off the price; scope is the seven metrics, nothing new.
- **Plan & Design** — wrote the requirements (BR-1 to BR-4), chose the container × week grain, specified the documented ticket-to-container cross-reference, set BR-4 (feed-failure alert) and the stale-table alerts, and sketched the pipeline: scheduled extracts → S3 landing zone → SQS-triggered loads → Snowflake raw → curated metric tables → Looker SQL Runner views. *Exit bar:* requirements accepted by infra; acceptance gate published before build.

- **Build & Test** — extract and load specs per system; the bridge table first; parity checks per metric; the parallel-run procedure, every mismatch explained by cause; the data-access security review that surfaced mid-build and cost two weeks. *Exit bar:* all seven metrics inside 1% of the manual pull for consecutive weeks; review closed.
- **Cutover & Go-Live** — the cutover memo; the Monday deck switched to the pipeline; the manual pull kept running as rollback until parity had held a week beyond the gate. *Exit bar:* first Monday off the pipeline shows the same seven numbers.
- **Hypercare / Close** — watched the failure alerts; triaged the first automated catch (a 4% ticket-sync drop) to a source cause; moved definitions into code; pushed the real container key upstream. *Exit bar:* accuracy 60% → 90%; the pipeline steers the review without me.

Influence and ownership. Mine: the as-is documentation, the grain choice, the bridge-table design, the seven frozen definitions, the pricing, the acceptance gate, the parallel-run procedure and the cutover memo. Not mine: the pipeline build and its alerts (infrastructure team), the real container key (Support), the security review (security team). I influenced by pricing the status quo in the BRD and making the cutover decision unarguable with a published gate.

> **Designed the process; others own it now.** The definitions are in code, the gate is a documented procedure and the alerts page a team, not me. **Trade-off put to leadership.** New metrics for stability (the seven were frozen, with a parking lot), and two weeks of date for a data-access review I should have planned.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY (RECORD VS MODELED LABELED)

- **$** — Over $100K a year, priced in the BRD, not saved: the BRD route gives $103,680 (30 → 6 h a week at an assumed $90/h); my model gives $100,360 ($30,160 hours + $70,200 decision risk). Both are priced, not claimed as savings. Realized candidate: 208 hours retired × $90 = $18,720 (modeled).
- **#** — Four systems → one pipeline; seven definitions in code; no longer a single point of failure (one engineer maintains the pipeline instead of one PM rebuilding it, Apple A3); zero WBR deliveries skipped through the build (record).
- **%** — System accuracy 60% → 90% (record); parity gate within 1% per metric for consecutive weeks (record); first automated catch a ticket-sync drop of about 4% (record).
- **Time** — the weekly snapshot (1.5–2 h by hand per the BRD) → automated; the data-access review cost two weeks (record).
- **Customer** — the VP and the core team steered on the same seven numbers the first Monday off the pipeline; Data Services and Support got tickets joined to containers for the first time.
- **Quality** — every parallel-run mismatch explained by cause — mostly late-arriving tickets on the manual side; silence on a failed feed replaced by an alert.

L6 LEVEL EVIDENCE — this story against the Amazon L6 functional rubric; every line is this story's record or labeled model

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	No one had written requirements for a program's operating metrics, and the cost-to-serve ratio had no join key. I defined grain, bridge and gate before anyone built.
Scope & influence	A pipeline owned by another organization, a key owned by Support and a review owned by security; I moved all three by pricing and publishing the gate, not by authority.
Execution trade-off + mechanism others now own	Seven metrics frozen for stability; two weeks lost to a review I should have planned. The mechanism others own: definitions in code, the parity procedure, the alerts.
Impact (long-term)	The weekly review no longer depends on one person, and the pipeline sees what the sheets could not — the first catch was a 4% drop.
Process improvement (standard work institutionalized)	Parallel-run-until-parity with a written gate; a bridge-then-fix-the-source rule for missing keys; a kickoff question about data-access approvals and their lead time.
Complexity & consensus	Four source systems, infra, Support and security with different priorities — one price in the BRD and one published gate aligned them.
Root cause at scale	The reason the number could be wrong was structural: the unit of cost (a ticket) and the unit of volume (a container) had no shared key or grain.

FIVE FACETS AT A GLANCE — the labeled structure the probing section below follows

1 · Data analysis	Ticket grain vs container grain; the key gap; late-arriving tickets; which mismatches were the manual side's fault; sample of what silence hid.
2 · Solution design	Sheets automation vs warehouse pipeline; container × week grain; bridge table vs waiting for the key; hourly vs daily feed; alarm design.
3 · Math & data logic	Join fan-out (0.667 vs 1.20); parity 0.42% pass and 1.25% investigate; alarm 4% vs 1%; BRD $129,600 → $103,680 vs model $100,360.
4 · Implementation	BR-1 to BR-4; parallel run to rollback; cutover memo; alert triage; security review as a dependency with a lead time.
5 · Probe questions	Seven numeric probes plus three trap drills: priced vs saved, 1.25% investigate-or-fail, sync-drop threshold.

PROBING — FIVE FACETS, THEN THE FULL DRILL

Facet 1 — Data analysis (what data, grain, joins, cuts, what it revealed)

What I read. Three data sets named in the BRD **RECORD-FROM-DOCS**: (1) Zendesk tickets — one row per ticket, created when the visibility service fails to start tracking a submitted container automatically, closed by Data Services; (2) Crux container data — pulled by hand into Google Sheets, keyed by container number; (3) Flexport core data in the warehouse. The unit of *cost* is a ticket; the unit of *volume* is a container; the ratio needs both, so I analyzed the grain at which each could be counted.

DATA SET	UNIT (GRAIN)	KEY IT CARRIES	WHAT IT IS USED FOR	WEAKNESS FOUND
Zendesk tickets	one row per ticket	Ticket ID; *no container ID*	numerator: tickets generated	cannot be joined to a container
Crux container data	one row per container	Container Number	denominator: active containers; coverage	a manual pull into Google Sheets, taken once a week
Flexport core data	one row per shipment / container	container number, client, mode	cuts: 4PL vs 3PL; SLA	not joined to tickets until a bridge exists

The seven metrics the BRD froze, and the grain each lives at

#	METRIC (BRD WORDING)	NUMERATOR	DENOMINATOR / CUT	GRAIN
1	Coverage — % of containers tracked (automated)	containers tracked with no human input	active containers	container-week stock
2	Coverage — % of containers tracked (with human inputs)	containers tracked after a human touch	active containers	container-week stock
3	Cost to serve — tickets generated	tickets	—	ticket, counted per week
4	Cost to serve — tickets generated / active container	tickets	active containers	needs the ticket → container join
5	Timeliness — 4PL % within SLA	containers inside SLA	4PL containers	container-week, 4PL cut
6	Timeliness — 3PL % within SLA	containers inside SLA	3PL containers	container-week, 3PL cut
7	Timeliness — delta (4PL vs 3PL)	metric 5 less metric 6	—	derived

Metric names are the BRD's. The numerator, denominator and grain columns are my design logic — the BRD does not define them. "Active container" is the review's own definition: cumulative inflow less containers 15 days past departed_terminal (Apple A2, grain 2).

What it revealed. (1) *No key, no ratio:* without a container ID on the ticket, tickets per active container could only be assembled by hand RECORD-FROM-DOCS. (2) *Grain decides the headline — in the real instrument:* the review workbook (Apple A2, SV_28.xlsx) shows 80.6% automated at event grain (1,991 of 10,289 events human-touched = 19.4%), 54.1% at ticket grain (538 auto, 456 human) and 40.0% on 17 Jan falling to 21.9% on 31 Jan at weekly stock — three grains, three answers, so the grain label travels with every number (record). My worked join example makes the same point for the cost ratio: 12 tickets over 4 of 10 active containers give 18 rows at ticket grain, 12 / 18 = 0.667 instead of 12 / 10 = 1.20, a ratio 44.4% too good (illustrative — my design example, not program data). (3) *Late-arriving tickets:* the manual snapshot missed tickets that arrived after the pull — nearly every parallel-run mismatch was the manual side (record, Apple A3). (4) *Silence was invisible:* a ticket-sync drop of about 4% after a routine update looked like a quiet week in the manual era (record).

Facet 2 — Solution design (options considered, chosen design, why)

DESIGN QUESTION	OPTIONS WEIGHED	CHOSEN	WHY (RECORD UNLESS MARKED)
Where the logic lives	Automate the spreadsheets · BI on a ticket export · warehouse pipeline + BI views	Warehouse feed + BI SQL views (the objectives in the document)	Joins to core data are one query; the manual pull stays a rollback, not the source.
Grain	Ticket · container · container × week	Container × week (Monday–Sunday, as the review reads it)	Numerator and denominator at one grain prevents fan-out; matches the weekly-stock grain the review already used (design logic; Apple A2 grain 2).
The missing key	Wait for Support to add a container ID · parse it from ticket text · cross-reference table now + real key upstream	Bridge now, key upstream	Ship with the bridge, fix the source: the program did not wait for another team's roadmap.

DESIGN QUESTION	OPTIONS WEIGHED	CHOSEN	WHY (RECORD UNLESS MARKED)
Feed frequency	Daily · hourly	Daily, preferably hourly (BR-3)	BR-3 says daily, preferably hourly; my whiteboard sketch has daily with hourly on the fast tables (Apple A3). The review is weekly, so daily is sufficient; hourly helps alarm latency.
Failure handling	Dashboard only · alert to support users · both	Alert when the feed fails (BR-4) and when sync rate drops	The first catch — a 4% drop — only exists because an alert does.
Cutover	Big-bang · parallel run to a gate · phased by metric	Parallel run to a 1% gate for consecutive weeks, manual pull as rollback	Makes the decision unarguable — the VP sees the same seven numbers.

The data elements, from the record (the BRD names no tables or columns)

ELEMENT	GRAIN / KEY	WHAT THE RECORD SAYS	SOURCE
Zendesk tickets (feed)	one row per ticket · Ticket ID	created when auto-tracking fails to start; closed by Data Services; the queue's UPDATED_BY_ID splits human from auto	BRD p1; Apple A2 grain 3
Crux container data	one row per container · Container Number	was a manual pull into Google Sheets; statuses include departed_terminal, in_review, out_of_network	BRD p2; Apple A2
Flexport core data	shipment / container	joined in Looker SQL Runner; carries the 4PL / 3PL and SLA cuts the metrics need	BRD objectives; metrics 5–7
Cross-reference table	one row per ticket–container pair	documented bridge so the join ships before the real key exists; data classes named, who can read what	Apple A3, G3
Feed and alerts	Zendesk → Snowflake, daily or preferably hourly	BR-3 feed frequency; BR-4 alert to SV Support users when the feed fails	BRD p4
Looker views (SQL Runner)	one row per metric × week	the seven definitions in SQL, no manual reconciliation	BRD use cases
Pipeline sketch (as I'd whiteboard it)	sources → scheduled extracts → S3 landing zone → SQS-triggered loads → Snowflake raw → curated metric tables	daily, hourly on the fast tables; SQL-runner queries behind the same WBR deck; stale-table alerts to the ops channel; one engineer maintains it	Apple A3 design sketch

The names above are the record's own (Ticket ID, Container Number, Looker SQL Runner, UPDATED_BY_ID, the three statuses). Table names, column names and the container-week fact are *design logic* I describe — not a production schema I recall.

Facet 3 — Math & data logic (four tables: Before · Fix substituted · After · Dollars)

Table 1 — Before: the problem in numbers (the three-grain row is record, Apple A2; the join illustration is illustrative; BRD pricing is record-from-docs)

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Manual cost of a snapshot	`1.5–2 hours to arrive at one week-over-week snapshot of seven metrics`	record-from-docs (BRD As-Is); a different measure from the about-four-hours-a-week-at-its-worst in Apple A1/A2 — do not stack them	1.5–2 h / snapshot
2	System accuracy	`system accuracy 60% (record); read as a weekly hit rate, (1 − 0.60) × 5 = 2 weeks in 5 off`	record (60%); the weeks-in-5 reading is my arithmetic, not a record	2 weeks in 5
3	Join fan-out at the wrong grain	`10 active containers; 12 tickets over 4 of them; rows after a ticket-grain join = 12 + (10 − 4) = 18`	illustrative example	18 rows for 10 containers
4	Ratio, wrong vs right	`wrong 12 / 18 = 0.667; right 12 / 10 = 1.20; understatement = 1 − 0.667 / 1.20 = 44.4%`	illustrative example	cost-to-serve 44.4% too good
5	BRD labor baseline	`3 people × 5 h × 2 reviews = 30 h a week; × 4 × 12 = 1,440 h; × $90 = $129,600 a year`	record-from-docs; arithmetic mine	$129,600 / yr
6	The printed monthly figure	`30 h × 4 × $90 = $10,800, not the printed $10,880; gap $80`	record-from-docs typo; arithmetic mine	$10,800
7	Three grains, one workbook (real)	`event grain: 1 − 1,991 / 10,289 = 80.6% automated; ticket grain: 538 / (538 + 456) = 54.1% automated`	record (Apple A2, SV_28.xlsx: 1,991 / 10,289 events; 538 auto / 456 human tickets)	80.6% vs 54.1%

Table 2 — The fix: the gates and alarms, values substituted (example values illustrative)

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Grain	`container × Monday-week; numerator (tickets) and denominator (active containers, touched in the last 15 days) counted at the same grain`	design; the 15-day active rule is record (Apple A2)	one row per container-week
2	Unmatched-ticket alarm	`unmatched share = 3 / 405 = 0.74% ≤ 1% → pass`	illustrative: 405 tickets, 3 unmatched, threshold 1%	0.74%
3	Parity — pass	`|70.9 − 71.2| / 71.2 = 0.42% ≤ 1% → pass (coverage: manual 71.2%, pipeline 70.9%)`	illustrative values; the 1% gate is the BRD acceptance rule (record)	0.42% → pass
4	Parity — investigate	`|405 − 400| / 400 = 1.25% > 1% → investigate: 5 late tickets, the manual side wrong, the pipeline right`	illustrative values (tickets: manual 400, pipeline 405 — not the real 538 / 456 counts)	1.25% → investigate
5	Sync-drop alarm	`alert if 1 − sync rate > 1%; first catch 1 − 0.96 = 4% = 4× the threshold`	catch is record; the 1% threshold is illustrative	4% → alert
6	Parity checks needed to cut over	`7 metrics × 2 consecutive weeks = 14 checks minimum`	the BRD says "consecutive weeks"; two is the minimum, the actual number is illustrative	≥ 14 checks

Table 3 — After: before → after

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	System accuracy	`60% → 90%; read as a weekly hit rate, (1 − 0.90) × 5 = 0.5 in 5 off`	record (60% → 90%); the weeks-in-5 reading is my arithmetic	2 in 5 → 0.5 in 5
2	Systems and key-person risk	`4 systems → 1 pipeline; one person stitching → one engineer maintaining it`	record (Apple A3); no bus-factor count is claimed	4 → 1 · no single point of failure
3	Manual hours	`~4 h a week × 52 = 208 h a year → ~0`	modeled	208 h retired
4	Silent data loss	`invisible → alert; first catch a 4% ticket-sync drop`	record	seen for the first time
5	Ticket-to-container join	`none → documented cross-reference → real key pushed upstream`	record (Apple A3); the join rate is not stated in any source — I would measure it	join key now upstream

Table 4 — The dollars: two priced baselines, one realized candidate — none claimed as savings

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	BRD route: after and difference	`$129,600 × (1 / 5) = $25,920; $129,600 − $25,920 = $103,680`	record-from-docs (BRD); priced, not claimed	$103,680
2	Model route: hours	`4 h × 52 = 208 h; 208 × ≈ $145 = $30,160`	modeled (rate illustrative; my model, not a source figure)	$30,160
3	Model route: decision risk	`52 weeks × 10% = 5.2 wrong-number weeks; 5.2 × $13,500 = $70,200`	modeled (both inputs illustrative; range $12K–$117K)	$70,200
4	Model route: total	`$30,160 + $70,200 = $100,360`	modeled; the record states "over $100K" as the priced baseline	$100,360
5	Do the two routes agree?	`($103,680 − $100,360) / $100,360 = 3.3%; both clear $100K by different bases (30 h a week vs ~4 h a week plus risk)`	my comparison; the two bases differ (30 h a week in the BRD vs ~4 h in my model)	3.3% apart
6	Realized candidate	`208 h × $90 = $18,720 (hours actually retired at the BRD rate)`	modeled; the honest version of "savings" — measure hours retired and restated Monday numbers	$18,720

Facet 4 — Implementation (phases, owners, rollout, cutover, controls, risks)

STEP	WHAT HAPPENED (RECORD UNLESS MARKED)	OWNER	CONTROL
Requirements	BRD with BR-1 to BR-4, seven definitions, as-is and pricing	me	accepted by infra; gate published before build
Bridge	documented ticket-to-container cross-reference so the join ships; real container ID pushed upstream	infra builds; Support owns the key	unmatched tickets counted and listed, never dropped
Build	scheduled extracts → S3 → SQS loads → Snowflake raw → curated → Looker SQL Runner (the whiteboard sketch); failure alerts	infrastructure team	BR-4 alert; BR-1 data protection
Security review	data-access review for ticket data carrying customer content surfaced mid-build; two weeks; re-sequenced; Monday review kept alive on the manual pull (Apple G3)	me (owned it upward immediately); security team	no review delivery skipped

STEP	WHAT HAPPENED (RECORD UNLESS MARKED)	OWNER	CONTROL
Parallel run	manual vs pipeline per frozen metric, within 1% for consecutive weeks, mismatches explained by cause	me	gate published; late-arriving tickets the usual cause
Cutover	the Monday deck switches to the pipeline; manual pull kept as rollback a week beyond parity	me (memo)	rollback = the manual pull
Hypercare	first alert triaged: 4% ticket-sync drop; definitions into code	infra + me	alerts reach a person, not silence

Risks named. The key gap, parity failure, one person as the single point of failure — and, as it turned out, the data-access review, which was not on the list. **Lean / Kaizen mapping.** The manual pull is motion and waiting waste; the seven frozen definitions are standard work; the parity gate is jidoka — stop the line when the pipeline and the reference disagree; the bridge table is poka-yoke for a missing key; "ship with the bridge, fix the source" is root-cause countermeasure at the right layer; every PDCA starts with the first alert.

Facet 5 — Probe questions (hardest follow-ups, numeric answers)

> **Why container × week?**
>
> Because the review reads weeks and the ratio needs numerator and denominator at one grain: tickets per active container. At ticket grain the container repeats once per ticket — my worked example gives 18 rows for 10 containers and a ratio of 0.667 instead of 1.20, 44.4% too good. At container-week every metric is a sum or a ratio of one table.

> **How did you join tickets that had no container ID?**
>
> A documented cross-reference table so the pipeline could ship, then a real join key pushed upstream so the fix outlived the workaround (record, Apple A3). The design I would add: count and list unmatched tickets, never silently drop them, with an unmatched-share alarm at 1% (threshold illustrative). I do not have a measured join rate to quote.

> **Why daily or hourly?**
>
> BR-3 says daily, preferably hourly; my whiteboard sketch is daily with hourly on the fast tables. The review is weekly, so daily is sufficient for the numbers; hourly matters for the failure alarm — a drop is caught the same day instead of the next.

> **What if parity had failed?**
>
> Then we would not have cut over: the manual pull stays the source of truth. Pass is within 1% on every frozen metric for consecutive weeks — 0.42% passes, 1.25% is investigate not fail (illustrative values), and in the cases I saw the explanation was late-arriving tickets on the manual side.

> **You wrote $103,680 in the BRD — what did you save?**
>
> Nothing I claim. It is a price: 3 × 5 × 2 × 4 × 12 × $90 (an assumed rate) = $129,600, less $25,920 after, $103,680 — and my own model prices it at $100,360 including decision risk. The realized candidate is the hours retired, 208 × $90 = $18,720, modeled, and I would measure it.

> **Why not wait for Support to add the container ID?**
>
> Because a program metric cannot wait on another team's roadmap; the bridge gave us the join now and the upstream fix made it cheap to retire the bridge. Ship with the bridge, fix the source.

> **What did the pipeline catch that you could not?**
>
> A ticket-sync drop of about 4% after a routine update (record, Apple A3). With my illustrative 1% alarm threshold that is 4× the threshold; in the manual era, silence read as a quiet week.

BUSINESS IMPACT MODEL — KPI TREE

```
The weekly review steers on numbers that are right, owned by more than one person, and alarmed when they
break
+- System accuracy 60% -> 90% (record)
+- Data model: container x week grain; bridge table (ticket <-> container); definitions in code
|    +- grain logic: 12 tickets / 10 containers = 1.20, not 12 / 18 = 0.667 (illustrative); real: 80.6%
event vs 54.1% ticket grain (Apple A2)
+- Gate: parity within 1% per metric, consecutive weeks (record; 0.42% pass / 1.25% investigate are
illustrative) | manual pull = rollback
+- Alarm: ~4% ticket-sync drop caught (record); alert threshold 1% (illustrative)
+- $ (priced, not saved): over $100K | BRD $103,680 | model $100,360 | realized candidate $18,720
(modeled)
(loop)  four systems by hand -> one person stitches -> one pipeline -> parity gate -> alarms
```

SOLUTION FLOW

```
Zendesk tickets (no container ID) --+                                          +--> Looker SQL Runner
views --> Monday deck
Crux container data ---------------+--> scheduled extracts -> S3 -> SQS loads -> Snowflake raw -> curated
metric tables
core data (4PL / 3PL, SLA) --------+              ^                                    |
          cross-reference table (documented; ticket <-> container)                     +--> alerts: feed
failure (BR-4), stale tables
parallel run: manual vs pipeline per metric, within 1%, consecutive weeks -> cut over -> manual pull kept
one more week as rollback
(pipeline stages: the whiteboard sketch, Apple A3; the BRD fixes the feed, the alert and the Looker SQL
Runner views)
```

SENSITIVITY — LOW / BASE / HIGH

LABOR BASIS FOR THE HOURS TERM	HOURS × WEEKS × RATE	BASIS
canon model: ~4 h a week	4 h × 52 wk × $145 = $30,160	modeled
one person, 5 h × 2 reviews	10 h × 48 wk × $90 = $43,200	illustrative
BRD: 3 people, 5 h × 2 reviews	30 h × 48 wk × $90 = $129,600	record-from-docs

The hours term alone moves 4.30× across the three bases (129,600 / 30,160), before the decision-risk term. That spread is why the number is a *price*, never a saving. The decision-risk term ($70,200) has its own range, $12K–$117K.

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

> The record number here is a price, not a saving. The manual way of producing the weekly review was priced in my requirements document at over a hundred thousand dollars a year — about a hundred and four thousand on its own arithmetic, thirty hours a week at an assumed ninety dollars an hour; my own model gets to about a hundred thousand with decision risk — and that price let the infrastructure team prioritize the build themselves. What I own is the design under it: a container-by-week grain so tickets and containers are counted together, a bridge table so the join could ship before the source was fixed, and a gate that said nothing switches until all seven metrics match the manual pull within one percent for consecutive weeks. System accuracy went from sixty to ninety percent, and the first automated catch was a ticket-sync drop of about four percent that nobody could have seen by hand. The realized version of the dollars is hours actually retired — about two hundred hours, roughly nineteen thousand at the requirements document's rate, modeled — and I won't call any of it savings.

IF CHALLENGED — THE FULL ANSWERS

"The requirements document says $103,680 saved. That's a lot for a spreadsheet."

It is a price, not a saving. The document's own arithmetic is 3 people × 5 hours × 2 reviews × $90, and its printed monthly figure does not match its annual. I say what the price was for — the BRD priced doing nothing so the infrastructure team could prioritize the build themselves — and I lead with system accuracy and the first catch, not dollars.

"Why build a pipeline for seven metrics?"

Because the ratio the program steered on — tickets per active container — had no join key and the number rested on one person stitching four systems by hand. Seven was the scope I held on purpose; new metrics went to a parking lot until the pipeline was stable.

"What's your actual technical contribution?"

The infrastructure team built the pipeline. Mine were the grain, the bridge-table design, the seven definitions, the pricing, the acceptance gate, the parallel-run procedure and the cutover memo — the part that decides whether a build is trusted.

20-SECOND VERSION AND NACF BRIDGE

20-SECOND VERSION

At Flexport the weekly review ran on four systems stitched by hand by one person. I wrote the requirements and the acceptance gate: a container-by-week grain, a cross-reference table for the missing ticket key, and a one-percent parity gate. System accuracy went from 60% to 90%, and the first automated catch was a ticket-sync drop of about 4%.

NACF BRIDGE — ONE SENTENCE

Capacity planning for inbound sits on the same data discipline: appointments, POs and containers must join at one grain (container × week or door × hour), unmatched records must be counted rather than dropped, and a feed that goes silent must raise an alarm — otherwise a quiet dock schedule looks like a healthy one.

BEHAVIORAL PACK — FOUR QUESTIONS THIS STORY ANSWERS, EACH A SEPARATE 90-SECOND STAR FROM A DIFFERENT FACET

B1 · "Give me an example of a complex problem you solved with a simple solution. What made the problem complex? How do you know your solution addressed the problem?" AIQB: Invent and Simplify Q1

Invent and Simplify FACET: SOLUTION DESIGN

Open (first two sentences): "The Monday review depended on four systems and one person assembling them by hand. I simplified it into one pipeline with seven frozen definitions and a bridge table for the one thing that was missing."

90-second STAR. S Four systems, one person, accuracy 60%, tickets with no container ID. **T** Produce the same seven numbers without that person. **A** I wrote the requirements, chose a container-by-week grain, specified a ticket-to-container bridge so the join could ship before the source was fixed, froze seven definitions, and set a one-percent parity gate with the manual pull as rollback. **R** Accuracy 60% → 90%; four systems → one pipeline; the review no longer depends on me.

Land: four systems → one pipeline; 60% → 90% · **Pivot to NACF:** a standard data contract for inbound: one grain, one bridge for missing keys, definitions in code.

Do NOT say: that I built the pipeline myself, or that the dollar is saved.

B2 · "Tell me about a situation that required you to dig deep to get to the root cause. How did you know you were focusing on the right things? What was the outcome? Would you have done anything differently?"

AIQB: Dive Deep Q2 | **Dive Deep** | FACET: DATA ANALYSIS

Open (first two sentences): "A join at ticket grain would have repeated each container once per ticket and made cost-to-serve look about forty-four percent better than it was. I caught that in the design, before it was in a deck."

90-second STAR. S Cost-to-serve per active container was the program's headline ratio, and its join key did not exist. **T** Make the ratio right before anyone steered on it. **A** I laid out the grain of each data set, showed with a worked example that 12 tickets over 4 of 10 containers gives 18 rows and a ratio of 0.667 instead of 1.20, and moved the model to container × week with numerator and denominator at the same grain. The parallel run then showed most mismatches were late-arriving tickets on the manual side. **R** A ratio that foots, and a first automated catch — a 4% ticket-sync drop — that the manual era could not have seen.

Land: 0.667 vs 1.20 (illustrative); 4% drop (record) · **Pivot to NACF:** any network ratio — utilization, cost per unit — is only as good as the grain of its numerator and denominator.

Do NOT say: that the 44.4% was a real finding in production — it is my design example; or that the manual numbers were never right.

B3 · "Tell me about a time when you generated a creative solution to a problem or project without requiring additional resources. What was the problem? What was the solution and how did you come up with it? What was the outcome?" AIQB: Frugality Q5 | **Frugality** | FACET: IMPLEMENTATION

Open (first two sentences): "I didn't ask for budget. I priced the manual process in the BRD, so the infrastructure team put the build on their own roadmap, and I held the scope to seven metrics."

90-second STAR. S The pipeline belonged to another organization with its own priorities. **T** Get it built without owning or funding it. **A** I priced the status quo in the BRD — its labor arithmetic gave $103,680 and my model $100,360 including decision risk; I held scope at seven metrics with a parking lot and used the existing BI tool's SQL runner. **R** Infrastructure prioritized the build itself; no new system bought; zero review deliveries skipped through the build.

Land: over $100K priced, not saved · **Pivot to NACF:** a business case for dock or yard automation: price the status quo, scope tight, no new tool unless the numbers demand it.

Do NOT say: the $103,680 as savings; or the hours basis as settled — it is the BRD's 30 hours a week at an assumed $90 an hour, not my ~4 hours.

B4 · "Describe a time when you refused to compromise your standards around quality/customer service, etc. Who was your customer? What was the result?" AIQB: Highest Standards Q1 | **Insist on the Highest Standards** | FACET: PROBE QUESTIONS

Open (first two sentences): "Nothing switched until all seven metrics matched the manual pull within one percent for consecutive weeks, with every mismatch explained by cause, and a failed feed raising an alert."

90-second STAR. S A VP steered the program by this number, and the pipeline was new. **T** Earn the cutover instead of announcing it. **A** I published the acceptance gate before build; ran the parallel run; investigated every mismatch — 1.25% is investigate, not fail (my illustrative example); kept the manual pull as rollback a week beyond parity; and required the failure alert (BR-4) before go-live. **R** The first Monday off the pipeline showed the same seven numbers, and silence stopped meaning health.

Land: 1% gate; 0.42% pass (illustrative) · **Pivot to NACF:** cutting over a yard-management or appointment system: parallel run to a numeric gate, rollback kept, alarm on silence.

Do NOT say: that the 1% threshold on the alarm was in the record — it is illustrative; or the number of consecutive weeks.

SAME STORY, THREE ANGLES — THREE CARDS, THREE OPENERS, THREE METRICS, THREE LPS

Data / analytical angle **Dive Deep**

Opener: “A ticket-grain join would have made cost-to-serve look forty-four percent better than reality — so before we built anything, I fixed the grain.”

Headline metric: 12 / 18 = 0.667 vs 12 / 10 = 1.20 (illustrative); 4% drop (record)

- Unit of cost (ticket) vs unit of volume (container); one grain: container × week.
- Unmatched tickets counted and listed, never dropped.
- Parity: 0.42% pass; 1.25% investigate (illustrative); mismatches the manual side's late tickets.
- Say "illustrative" on every example number.

Conflict / influence / backbone angle **Have Backbone; Disagree and Commit**

Opener: “Everyone wanted one more metric during the build; I held the scope at seven with a parking lot, and shipped the bridge instead of waiting for Support.”

Headline metric: seven frozen metrics; one bridge table

- Stability over coverage — a documented trade-off, not an oversight.
- Bridge now, real key upstream: another team's roadmap did not hold the program.
- Priced in the BRD so infra could prioritize it themselves — influence without authority.
- My seat (Apple A3): the BRD, the seven definitions, the parallel-run gate, the acceptance test, the cutover call; infra built the pipeline.

Honest failure-and-learning angle **Earn Trust**

Opener: “I discovered the data-access security review mid-build instead of planning it — two weeks — on the pipeline that was supposed to retire my own manual review.”

Headline metric: two-week security-review miss; zero Monday reviews skipped

- I owned it upward immediately: the slip was scoping, not engineering — the BRD priced the build and never the review (Apple G3).
- Ticket data carries customer content, so the access review is a gate with lead time, not a formality; I had treated it as a formality.
- I re-sequenced instead of stalling: the parallel run kept the Monday review alive on the manual path, so no review week was skipped.
- I closed the review properly — cross-reference table documented, data classes named, who could read what — and now every data program starts with "whose approval does this data need, and how long does that take?"
- Not a dollar claim: the miss cost margin, not delivery. Do not mix in the $103,680 here.

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS

"Your document says $103,680 saved. So you saved over a hundred thousand?"

Numeric answer. No. 3 × 5 × 2 × 4 × 12 × $90 (an assumed rate) = $129,600; after = $25,920; difference $103,680 — a priced labor estimate, and the printed monthly figure ($10,880) does not match its annual ($10,800 × 12). My model prices the baseline at $100,360 ($30,160 + $70,200). The realized candidate is the hours actually retired: 208 × $90 = $18,720, modeled.

Say exactly: “It's a price, not a saving — about a hundred and four thousand on the document's labor basis, about a hundred thousand in my model. The realized version is hours retired, about nineteen thousand, modeled.”

"Pipeline 405 tickets, manual 400. That's a 1.25% gap — a failure?"

Numeric answer. Investigate, not fail (illustrative values): |405 − 400| / 400 = 1.25%, just over the 1% gate, and the explanation in the cases I saw was five late-arriving tickets on the manual side. Contrast 70.9% vs 71.2% coverage: 0.42%, pass. (Example values are illustrative.)

Say exactly: “A gap of one-point-two-five percent is over the gate, so we investigate — and the cause was late tickets the manual pull missed. Coverage at point-four-two percent passed.”

"How do you know the 4% drop wasn't noise?"

Numeric answer. The alarm rule is 1 − sync rate > 1% (threshold illustrative); the observed 1 − 0.96 = 4% is 4× that threshold, and the record says it was a ticket-sync drop of about 4% after a routine update, invisible in the manual era; I did not keep the triage detail beyond that. A threshold like this is tuned from weeks of normal variation, which I would pull from the history.

Say exactly: “Four percent is four times the alarm threshold, and in the manual era it would have looked like a quiet week. I triaged it to a source cause, not to noise.”

Question bank — likely questions for this interviewer, with a one-line answer plan

NEW

Behavioral and functional questions a hiring manager for NACF Supply Chain is likely to ask, in rough order of likelihood. Each plan points at a packet story or a named backup in the master packet. Stories allocated to other interviewers are referenced as pointers only. v2 adds rows 17–28 for the five new primaries; the Router at the front maps all 16 Leadership Principles.

#	LIKELY QUESTION	ANSWER PLAN (ONE LINE)	STORY
1	**Tell me about yourself.**	The 75-second newest-to-oldest script from the master packet: Sephora (one signed "available"; dual-DC WMS migration) → Flexport (the review; $0.66 → $0.03) → Elementum (measured lanes, $1.5M out) → Manhattan (99% fill). End on "design the supply chain, keep it honest in a weekly review — at network scale."	Master TMAY
2	**Why Amazon, why now?**	Three reasons — the forecast (Elementum lanes), the weekly review (Flexport), one version of the truth (Sephora) — and "what I went to Sephora to build is live."	Master Why Amazon
3	**Tell me about your most significant delivery.**	S11 pitch; end on CTS $0.66 → $0.03 across 7 → 68; stop.	S11
4	**Tell me about a time you changed a plan that was already committed.**	S12 pitch; private-first; 66% less effort, value month 6; ~$5M once.	S12
5	**Tell me about a time leadership doubted your program.**	S11 Discovery: accepted the critique as being about evidence; built the review; left the critic steering by the numbers.	S11
6	**How do you make trade-offs between speed and quality?**	S11: board no faster than automation matures; wave 3 held publicly. S12: confidence buffers over a fast optimistic plan.	S11 / S12
7	**Describe how you would run your first 90 days in NACF Supply Chain.**	Book of record and primary metric first; stocks-and-flows map of the process; the invariant broken today; 3 key results with denominators; a weekly input/output review by week 6 (master §3.0, seven steps).	Master §3.0
8	**How would you decompose a complex network problem (e.g., inbound placement cost rising)?**	Open as the master's §3.99 script: book of record + metric → stocks and flows → broken invariant → minimal design → sequence by Reach × Impact × Confidence ÷ Effort → one metric, one labeled dollar.	Master §3.99
9	**Tell me about a time you failed.**	Full failure story here: S11-B (the pilot ran later than the first testing plan — testing under-sized, monitoring late, now sized on hop count) is the primary; the master's UAT-crash bench story (§4.3 — numeric entrance criteria ever since) is the backup. S18's RF miss (Goforth) and S16's security-review miss (Josyula) are held for other interviewers — pointers only; S4 (the in-transit rule I got wrong) is Lan's backup pointer, so keep it clean.	S11-B · Bench §4.3
10	**How do you measure success for a process you designed?**	A KR without a denominator is not a KR: seven frozen metrics with owners, honest denominators (15-day active rule), inputs tagged to outputs.	S11

#	LIKELY QUESTION	ANSWER PLAN (ONE LINE)	STORY
11	**What's a number you refused to report?**	The 99.4% three-touch week — printed as a data miss.	S11
12	**What would your current manager say you need to work on?**	Start the review at kickoff rather than after the critique (S11); back-test a rule before publishing it (master S4 lesson, pointer only).	S11 / S4 pointer
13	**How would you think about inventory-placement strategy for a network like mine? (placement was her 2017–22 world — public-profile inference)**	S11's logic translated: publish the selection bar before the first node (graduation criteria ≈ placement criteria), calibrate per node (~50 containers ≈ a trial volume), hold a node in public when it misses. Then master §3.99: book of record → stocks and flows → broken invariant → minimal design.	S11 / §3.99
14	**How do you decide connectivity in a crossdock network — which nodes, which flows?**	S12's sequencing logic: rank flows by benefit × impact ÷ effort at the work-item grain (interactions eliminated per flow), FCL-first as "highest-volume flow first," a reversal trigger written per node before the swing.	S12
15	**You ran launch readiness for 50+ buildings — what does readiness mean for a process launch? (her 2014–17 world — public-profile inference)**	FC-readiness discipline translated: a written entry bar per wave (the six criteria), a launch gate on real volume (100 containers × 7 checks), a published rollback rule (the reversal trigger), and the hold taken in public when the bar misses.	S11 / S12
16	**Tell me about building a team or capability from scratch.**	S11's mechanism answer: input owners across nine teams recruited to sign the definitions they would be red against; the review run by hand until the pipeline (S16-A, in this packet) carried it; wave teams grown into owners — capability built while delivering, not before.	S11
17	**Walk me through a data analysis that changed a decision.**	S11-A: the 22× cost-to-serve drop split into 6.0× (60% → 10% of containers needing a human) × 3.67× (touches on each); the 3-touch 99.4% week discarded. Backup S12-A (P95 by region, then by path).	S11-A / S12-A
18	**How would you design the data model behind an operating metric?**	S16-A: one grain (container × week), numerator and denominator at that grain, a documented cross-reference for the missing key, a 1% parity gate and a feed-failure alert — the BRD names no tables, so the join, the grain and the artifacts are the story.	S16-A
19	**How do you decide a product or process is ready to launch?**	S11-B: four test gates, a 100-container ledger × 7 checks, six published graduation criteria — and own that the pilot ran later than the first testing plan.	S11-B
20	**How do you retire or migrate a customer base without stranding anyone?**	S11-C: nine segments, three questions each, concentration first (3 brokers = 75.0% of containers), dated actions, the dissent on the page.	S11-C
21	**Tell me about diagnosing a regional performance problem.**	S12-A: P95 by region (Asia 21.19 s vs US 3.3 s = 6.42×), then by path (static vs dynamic), reversible fixes first, 32 smoke checks a change.	S12-A
22	**How do you know a number is right before you steer on it?**	S16-A parity gate (≤ 1% for consecutive weeks, mismatches explained by cause); S11-A footing and honest denominators; S11-C re-footed the doc's own table.	S16-A / S11-A / S11-C

#	LIKELY QUESTION	ANSWER PLAN (ONE LINE)	STORY
23	**How would you apply Kaizen / Lean here? (her trainer background — public-profile inference)**	Waste and standard work in S11-A (3.67 touches; seven frozen definitions); jidoka in S11-B (hold wave 3); genchi genbutsu and PDCA in S12-A; poka-yoke in S16-A (bridge table, parity gate). Say the gate, never the slogan.	S11-A / S11-B / S12-A
24	**How do you decide what to fix first?**	S11-B Pareto: 41 of 59 failing containers first broke at two hops (69.5%) — fix those; S11-C concentration; S12 benefit × impact ÷ dev-weeks.	S11-B / S11-C / S12
25	**Tell me about a metric that looked great and was not.**	S11-A: 99.4% on three touches — printed as a data miss; a 95% interval on N = 3 is wider than the metric.	S11-A
26	**Tell me about something that took longer than planned.**	S11-B: the first testing plan targeted early November 2021 and the pilot launched in December; the documents disagree on whether that was late, so I say "later than the first testing plan" — testing effort was under-estimated and monitoring arrived late; now sized on hop count.	S11-B
27	**How would your container-week grain apply to inbound capacity? (transferability probe)**	S16-A bridge: one grain for appointments, POs and containers (container × week or door × hour), a documented cross-reference for missing keys, an alert on a silent feed. Then the booklet: doors × hours × unload rate; the 85% knee.	S16-A
28	**Why should I believe your dollars?**	Every dollar carries its basis. Record: 7 → 68, $0.66 → $0.03, ~$5M once. Modeled: ≈ $50K direct CTS, $1.52M run-rate. Priced, not saved: S16-A's $103,680 / $100,360. See the NUMBERS page.	S11 / S12 / S16-A

Backup bench — use only if a primary doesn't fit

Three fallbacks for the hiring manager, none of them another interviewer's primary: S9 (Elementum — the 597-lane Pareto and the ≥95% gate, for Backbone / Think Big / Highest Standards if S11 and S12 are spent), S19 (Elementum · Walmart-client — the promise buffer as one governed dial; a design-flavored Frugality / Invent & Simplify alternate, all model, illustrative labels intact) and S13 (Manhattan — Cyber Monday at 4 AM, the Bias for Action / Customer Obsession alternate). Tell S11 and S12 first.

Bench discipline. The two (or four) primaries above are the stories to tell first. Reach for a bench story only when the question genuinely does not fit a primary, or when the interviewer asks for "another example" on an LP already spent. Each entry is a 60-second pitch, a compressed STAR, one results line and two probes — enough to answer and stop; no full probing bank or derivation. Where a bench story is another interviewer's primary, the red note says so: use it only if the question demands it, and keep the facts identical to that packet.

BACKUP — ONLY IF ASKED S9 — Elementum — 1,000 supplier/carrier routes asked, 597 built first: X12 EDI onboarding behind a ≥95% valid-ASN cohort gate

LPs this backup can serve: Have Backbone; Disagree & Commit (primary — 597 vs 1,000, two levels up) · Deliver Results · Insist on the Highest Standards (the gate held twice) · Think Big (the staged 1,000-lane vision) · Broad Responsibility (small carriers kept inside the standard by the portal floor)

Basis. I owned the scope analysis and the onboarding standard, influencing an executive two levels above my sponsor; engineers built the maps and harness to the standard; Transportation owned the carrier relationships. Cohort sizes and the number of cohorts are not in the record — do not quote them.

60-SECOND PITCH — STOP ON THE PRIMARY METRIC

Situation. The Global Head of Supply Chain wanted inbound visibility on 1,000 lanes in two months; shipment-data completeness was 60% and high-value lanes were blind. **Task.** I owned the scope analysis and the onboarding standard, influencing an executive two levels above my sponsor. **Action.** Discovery: a spend Pareto — 597 lanes carried 80% of freight spend — pre-validated with Transportation and Procurement before I took it up. Plan & Design: the onboarding standard (X12 850/855/856/940/945/214/997 with an XML/portal floor — "the standard was the data, not the transport") and a cohort gate of ≥95% valid ASN. Build & Test: a mapping-and-test harness and a scorecard per lane. Cutover: 597 live in month one; one cohort failed the gate twice on a timestamp format and I held it both times. Hypercare: completeness scorecards to 95%; ~200 lanes the next wave behind the same gate. Lesson: automating dirty data manufactures confident wrong answers — the gate is the product. **Result.** Primary metric: inbound shipment-data completeness 60% → 95%. Freight spend −10% ≈ $2M in six months (record); 597 lanes = 80% of spend live in month one; adoption 8×.

COMPRESSED STAR

- **S —** 1,000 global lanes asked in two months — scope, schedule and quality all fixed; completeness 60%; lanes differed by orders of magnitude in spend and carriers differed in EDI capability.
- **T —** Own the scope analysis and the onboarding standard; take the re-scope two levels up with the evidence attached.
- **A —** Spend Pareto (597 = 80% of spend) pre-validated so no lane owner could contradict it in the room; standard + ≥95% valid-ASN gate published to carriers before cohort one; harness so later cohorts were mostly configuration; held a failing cohort twice; ~400 lanes carrying ~20% of spend deferred — priced in spend share, not lane count.
- **R —** Completeness 60 → 95%; 100% visibility on high-value lanes; 597 lanes live month one; freight −10% ≈ $2M in six months (record); method written up as the sourcing SOP.

RESULTS LINE

Completeness 60% → 95% (record) · 597 of 1,000 lanes = 80% of freight spend live in month one (record) · freight spend −10% ≈ $2M in six months (record — kept as measured, never annualized) · adoption 8× (record) · ≈$0.4M/yr document-handling labor (modeled add-on).

THE MATH — STEP-BY-STEP DERIVATION

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Shipment-data completeness	`480 / 800 = 60%`	expected = 200 shipments × 4 milestones = 800; received 480 (illustrative volumes; 60% record)	60% — 2 of 5 events missing
2	What blindness costs	`off-guide spend unseen · premium modes by habit · chase calls per late shipment`	record problem	no instrument, no lever
3	Manual documents	`597 lanes × ~50 shipments × 3 docs ≈ 90,000 docs/yr`	illustrative volumes	~90K docs/yr keyed by hand

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Spend Pareto	`S(k) = cumulative spend share; S(597) = 80%`	lanes sorted by annual freight spend (record)	597 of 1,000 lanes carry 80% — build them first
2	Cohort gate	`valid-ASN rate ≥ 95% in test before activation`	published to carriers before cohort one (record)	one cohort failed twice on a timestamp format — held both times
3	Long-tail floor	`XML / portal when EDI is absent`	"the standard was the data, not the transport" (record)	small carriers kept inside the standard
4	Completeness after	`760 / 800 = 95%`	illustrative volumes; 95% record	95%; high-value lanes 100%

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Shipment-data completeness	60%	95%; high-value lanes 100%	record
2	Lanes live in month one	0	597 = 80% of freight spend	record
3	Freight spend on onboarded lanes	base	−10% ≈ $2M in six months	record — measured, never annualized
4	Document handling	~90K docs/yr keyed	X12/XML validated, portal floor for the tail	modeled

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Implied addressable base	`$2,000,000 / 10% = $20,000,000/yr`	derived from the record pair, stated as such	≈$20M/yr
2	The record result	`$20M × 10% = $2M in six months`	record	≈$2M — said as measured
3	Slice — routing-guide compliance	`~$0.8M of the $2M`	off-guide spend caught by 856/214 (modeled split)	~$0.8M

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
4	Slice — mode discipline	`~$0.6M of the $2M`	premium modes → ocean/ground when the ETA is trusted (modeled split)	~$0.6M
5	Slice — expedites + detention	`~$0.6M of the $2M`	events replace chase calls (modeled split)	~$0.6M
6	Split check	`0.8 + 0.6 + 0.6 = $2.0M`	the slices decompose the record — they never add to it	= the record $2M
7	Document labor	`90,000 × 6 min = 540,000 min; / 60 = 9,000 h; × $45 = $405,000`	illustrative volumes; benchmark rate (modeled add-on)	≈$0.4M/yr

TWO PROBES

> **You defied a Global Head of Supply Chain's number. How?**
>
> With the spend curve and the lane owners' validation attached — 597 lanes carried 80% of the spend, so the phased plan was argued in spend share, not lane count. He accepted the phasing off the curve; I then committed to the remainder behind the same gate and delivered it.

> **Is the $2M annualized?**
>
> No — it is the record as measured: minus ten percent on the onboarded lanes' spend in six months. My three-way split (routing-guide compliance ~$0.8M, mode discipline ~$0.6M, expedites and detention ~$0.6M) decomposes the record; it never adds to it.

Canon numbers (basis labels): 60% → 95% completeness (record) · 597 / 1,000 lanes = 80% of spend (record) · −10% ≈ $2M in 6 months (record) · ≥95% valid-ASN gate, held twice (record) · 8× adoption (record) · ≈$0.4M/yr labor (modeled). Never: cohort counts or sizes; never double the $2M into a run-rate.

BACKUP — ONLY IF ASKED S19 — Elementum (client: Walmart Marketplace) — the delivery-promise buffer rebuilt as priced risk: one governed dial, +32 points of fast-promise share at the same 95% floor (all model, no record dollar)

LPs this backup can serve: Dive Deep (alternate when S8/S10 are spent) · Invent and Simplify (alternate) · Frugality (speed bought with zero new spend) — design-flavored probes

Basis. Engagement lead for the promise-policy workstream; the client's promise-engineering and data-science teams owned and built the engine and the transit models — I never configured or deployed any platform. Every quantity is from the engagement's illustrative twelve-cohort model — say "the model" in the same breath; there is no production dollar and none is ever promoted. Labels (metro two-day, mountain rural) are the model's illustrative cohort names.

60-SECOND PITCH — STOP ON THE PRIMARY METRIC

Situation. A marketplace client printing delivery dates on inventory it never touches: promised date = order time + seller handling + predicted transit + a safety buffer — and the buffer was a flat 1.10 days on every lane regardless of variability. In the engagement model — twelve lane cohorts, about a million orders a week, transit σ from 0.22 to 1.60 days — that flat buffer printed 95.8% accuracy but put only 7.6% of orders on a fast promise: dense metro lanes over-insured and fat-tailed rural lanes under-insured at the same time. **Task.** Own the decomposition, the alternatives, the validation gates and the governance recommendation; the client's data science and engineering did not report to me. **Action.** Discovery: the buffer-waste audit — the flat buffer bought Φ(5.0), near-certainty, on the tightest cohort and only Φ(0.69) ≈ 75% on the widest. Plan & Design: four policies on one comparison table — uniform, σ-proportional with one governed dial, minimum-days at the floor, profit-optimal on priced breach economics. Build & Test: b = 1.645σ holds 95% on every cohort by construction; the equimarginal check proved the optimum; the Q4 drill showed a frozen summer dial breaking the floor. Cutover: four shadow weeks against logged live orders before any displayed promise. Hypercare: the dial published in the weekly review header, re-solved before peak. **Result.** Primary metric: fast-promise share 7.6% → 39.6%, +32 points at the held 95% floor; average promised day 3.09 → 2.75; +$255K a week, about $13.3M a year — all on the illustrative book, and I say "the model" in the same breath.

COMPRESSED STAR

- **S —** A flat 1.10-day buffer on every lane: 95.8% headline accuracy hiding over-insurance on tight lanes and under-insurance on loose ones; fast-promise share 7.6% (model).
- **T —** Lead the promise-policy workstream: decompose the waste, put priced alternatives on one table, design the gates, leave a governance instrument — not a tuning habit.
- **A —** Promise identity and accuracy factorization; buffer-waste audit; four policies on one table; proofs (Φ(1.645) = 0.95 per cohort, equimarginal check, Q4 drill at ~1.45× σ); shadow mode for four weeks; the dial k owned by a business owner and printed every Monday.
- **R —** Fast-promise share 7.6 → 39.6% (+32 pts) at exactly the 95% floor; average promised day 3.09 → 2.75; +$255K/wk ≈ $13.3M/yr — model, labeled; the widest cohorts got honestly slower promises (1.10 → 2.63 days) on purpose.

RESULTS LINE

Fast-promise share 7.6% → 39.6% (+32.0 points) at a held 95.0% floor (model) · average promised day 3.09 → 2.75 (model) · +$255K/wk ≈ $13.3M/yr vs uniform (modeled on the illustrative ~1M-order book) · the profit-optimal frontier (97.8% accuracy, ≈ +$20M/yr) handed to Finance as a priced decision — shown, never claimed, never merged with the $13.3M.

THE MATH — STEP-BY-STEP DERIVATION

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	The promise identity	`EDD = t_order + handling + transit_pred + b; kept ⇔ (handling_err + transit_err) ≤ b`	per order; b = buffer in days (record-from-docs identity)	the buffer is the only policy term
2	Kept-promise probability per lane	`P(kept) = Φ(b / σ)`	ε ~ N(0, σ²) per cohort — whiteboard version; production uses the empirical quantile (record-from-docs)	accuracy is a function of b and σ only
3	Incumbent buffer	`b = 1.10 days on every lane`	uniform policy A (illustrative model)	1.10 d everywhere
4	Tightest cohort, z-score	`z = b / σ = 1.10 / 0.22 = 5.0; Φ(5.0) ≈ 0.9999997`	metro cohort σ = 0.22 d (illustrative model)	near-certainty bought — promise needlessly slow
5	Widest cohort, z-score	`z = 1.10 / 1.60 = 0.6875; Φ(0.69) ≈ 0.754`	mountain-rural cohort σ = 1.60 d (illustrative model)	≈75.4% kept — a known-loss book
6	Portfolio print	`accuracy 95.8% · fast share 7.6% · avg promised day 3.09 · profit $5.69M/wk`	order-weighted across 12 cohorts, ~1M orders/wk (illustrative model)	a green headline hiding both failures
7	The asymmetry	`padding fails silently (lost conversion files no ticket); cutting fails loudly (breaches do)`	record-from-docs — why the system drifted slow	bias toward slow, unowned

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	One governed dial	`b_lane = k × σ_lane; Φ(k) = floor ⇒ k = 1.645 for 95%`	Φ(1.645) = 0.95 under normal errors (record-from-docs design)	k = 1.645, one number for the book
2	Tightest cohort re-buffered	`b = 1.645 × 0.22 = 0.36 days`	σ = 0.22 d (illustrative)	buffer 1.10 → 0.36 d; 0.74 d of speed harvested
3	Widest cohort re-buffered	`b = 1.645 × 1.60 = 2.63 days`	σ = 1.60 d (illustrative)	buffer 1.10 → 2.63 d — slower on purpose, kept honest
4	Every cohort at the floor	`P(kept) = Φ(1.645 × σ / σ) = Φ(1.645) = 0.95`	by construction (design)	95.0% everywhere; no cohort subsidizes another
5	Portfolio after	`accuracy 95.0% · fast share 39.6% · avg day 2.75 · profit $5.94M/wk`	illustrative model output, policy B	+32 pts fast share at the floor
6	Peak regime rule	`σ_Q4 ≈ 1.45 × σ; frozen k ⇒ z = 1.645 / 1.45 = 1.13; Φ(1.13) ≈ 0.87 per fully-inflated lane; portfolio prints 91.9% < 95%`	Q4 drill (illustrative model)	k re-solved and published in October, never frozen
7	Shadow gate	`4 consecutive weeks logged ≥ floor, contacts flat → promote; else hold`	promotion bar (design)	rehearse against reality before any displayed date

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Fast-promise share (≤2-day)	7.6%	39.6% (+32 pts)	illustrative model
2	Portfolio promise accuracy	95.8% (split: ~100% / 75.4%)	95.0% — the floor, held on every cohort	illustrative model
3	Average promised day	3.09	2.75 (−0.34)	illustrative model
4	Weekly modeled profit	$5.69M	$5.94M (+$255K)	illustrative model
5	Owner of the speed-accuracy trade	implicit, in the last model tune	one governed dial, published weekly, re-solved per regime	engagement design record

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Weekly profit, policy A	`$5,690,000 / wk, taken from the model`	illustrative model output	$5.69M/wk
2	Weekly profit, policy B	`$5,940,000 / wk, taken from the model`	illustrative model output	$5.94M/wk
3	Weekly delta	`$5,940,000 − $5,690,000 = $250,000 (the model's precise print: +$255K)`	rows 1–2 (illustrative)	≈ +$255K/wk
4	Annualized	`$255,000 × 52 = $13,260,000`	row 3 × 52 weeks (modeled)	≈ $13.3M/yr — "the model," said in the same breath
5	Frontier: policy D delta	`$6,070,000 − $5,690,000 = $380,000/wk; $380,000 × 52 = $19,760,000`	illustrative model output; ×52 modeled	≈ $20M/yr — handed to Finance, never claimed
6	Why D holds 97.8%	`breach EV $12 > margin-per-promise-day $6.50 ⇒ optimum above the 95% floor`	$12 and $6.50 are the model's stated assumptions	the floor and the economics disagree — a governance finding
7	Headline	`≈ $13.3M/yr modeled; record dollars: none`	rows 3–4	≈ $13.3M/yr, always labeled

TWO PROBES

> **The whole story rests on an illustrative cohort set.**
>
> It does, deliberately — the model exists so the argument happens in numbers instead of adjectives. If the real σ looks nothing like the model's, k changes and the lane ranking changes; what survives any parameter set is the structure: buffers risk-proportional, the last buffer-day buying the same accuracy everywhere, and a floor that disagrees with the breach economics treated as a governance finding.

> **Why one dial instead of per-lane learned buffers?**
>
> Data science wanted per-lane learned buffers — more model, more value, invisible governance. I priced the difference and recommended the one-dial policy first: it captures most of the value, it is auditable, and σ improvements flow into speed automatically and visibly. The no went into the comparison table as a priced row, not a meeting minute.

Canon numbers (basis labels): 7.6% → 39.6% fast-promise share (+32 pts, model) · 95.8% → 95.0% accuracy held at the floor (model) · 3.09 → 2.75 promised days (model) · +$255K/wk ≈ $13.3M/yr (modeled) · 12 cohorts, ~1M orders/wk, σ 0.22–1.60 days, k = 1.645 (illustrative model) · breach ≈$12 vs margin ≈$6.50 (model assumptions). Never a production dollar.

BACKUP — ONLY IF ASKED S13 — Manhattan — Cyber Monday, 4 AM: allocation across 3 DCs and 100 stores when the scheduler died

LPs this backup can serve: Bias for Action (primary) · Customer Obsession (primary backup — the promise ranked first) · Deliver Results

Basis. OMS consultant on allocation, promising and the OMS–WMS handshake; engineering fixed the scheduler once I isolated it; the post-mortem mechanisms were mine to drive. $8M / $6M / 99% are record; the margin figures are my model at benchmark rates. Older story — if asked for recent, pair with the UDC robotics throttle (S2): same muscle, 2024–25.

60-SECOND PITCH — STOP ON THE PRIMARY METRIC

Situation. Manhattan OMS consultant on allocation and promising across 3 DCs and 100 stores; 4 AM Cyber Monday the VP called — backorders piling with inventory present, ~$6M of sales at risk against a 95% fill-rate goal. **Task.** Own the response before the root cause was known. **Action.** Discovery: the contradiction (ATP > 0, backorders rising) was the entry bar to declare an incident. Plan & Design: I ranked by promise-at-risk, not FIFO; node choice = the promise — near 0.85 days vs far 4.60. Build & Test: one bridge, every rebalance timestamped; reason-coded alerts I had already built. Cutover: rebalanced so no DC drowned; status every two hours until 9 PM. Hypercare: root cause — the allocation scheduler died silently at the daylight-saving change; the post-mortem shipped a heartbeat, a DST checklist, a 3σ page rule and a rehearsed rebalance playbook. Lesson: decide reversibly, log it, find the cause later. **Result.** Primary metric: peak fill rate — 95% goal → 99% delivered. ~$8M of peak sales protected against ~$6M at risk (record); my model puts that at ≈$3.2M of gross margin at a 40% benchmark margin; structural stockouts −20% over the engagement.

COMPRESSED STAR

- **S —** 4 AM Cyber Monday: backorder lines piling with inventory present; promises aging; ~$6M at risk against a 95% fill goal; nobody had written a clearing rule for failure.
- **T —** Own the response before the cause was known, without making it worse.
- **A —** Declared the incident on the contradiction; clearing rule — promise-at-risk, not FIFO — written on the bridge log in the first hour so nobody re-argued it at noon; rebalanced across three DCs; two-hourly status; isolated the DST scheduler death through my own reason-coded alerts; blameless post-mortem → heartbeat, DST checklist, 3σ page rule, rehearsed playbook.
- **R —** Fill 99% vs the 95% goal; ~$8M protected vs ~$6M at risk (record pair); structural stockouts −20% over the engagement; the next peak ran boring.

RESULTS LINE

Peak fill 99% vs the 95% goal (record) · ~$8M of peak sales protected vs ~$6M at risk (record pair — one-time sales that didn't die, never a saving) · ≈$3.2M gross margin at a 40% benchmark (modeled) · structural stockouts −20% over the engagement (record) · detection moved from a VP phone call to one heartbeat interval.

THE MATH — STEP-BY-STEP DERIVATION

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	4 AM state	`scheduler dead; backlog = 30,000 orders; ~$6M of sales at risk vs the 95% fill goal`	record risk pair; backlog illustrative	the bridge call
2	FIFO failure	`FIFO clears by arrival — cheap, distant-promise orders first while at-risk promises age`	record rule problem	value-blind clearing

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
3	Naive node loads	`DC1: 22,000 / 10,000 = 2.2 days; DC3: 2,000 / 6,000 = 0.33 days`	capacities 10K / 8K / 6K orders/day (illustrative)	worst node 2.2 days behind while another idles
4	No liveness detection	`a dead scheduler was found by a VP at 4 AM, not by a page`	record problem	detection by seniority

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Promise-at-risk ranking	`risk = value × urgency(promise − now); clear descending`	on the bridge log in hour 1 (record rule)	at-risk promises first, not first-in
2	Node choice = the promise	`T = handling + transit: near 0.85 d vs far 4.60 d; 4.60 − 0.85 = 3.75 d`	record pair	−3.75 days per re-pointed order
3	Load levelling	`rebalance 30,000 → 12,500 / 10,000 / 7,500: 12,500/10,000 = 1.25; 10,000/8,000 = 1.25; 7,500/6,000 = 1.25 days`	load = queue / capacity (illustrative)	worst slip 2.2 → 1.25 days
4	Liveness page (post-mortem)	`page if x < μ − 3σ = 1,200 − 3 × 150 = 1,200 − 450 = 750/hr`	μ = 1,200 allocations/hr, σ = 150 (illustrative); a dead scheduler reads 0/hr	caught in one interval, not by a VP

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Peak fill rate	95% goal	99% delivered	record
2	Peak sales	~$6M at risk	~$8M protected	record pair — one-time event
3	Worst-case promise slip	2.2 days	1.25 days	illustrative walk
4	Detection	a VP at 4 AM	one interval via the 3σ page	post-mortem design
5	Structural stockouts	—	−20% over the engagement	record

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Margin protected	`$8,000,000 × 40% = $3,200,000`	benchmark margin 35–45% (modeled)	≈$3.2M one-time
2	Orders at risk	`$6,000,000 / $150 = 40,000 orders`	AOV benchmark	40,000 orders
3	Cancels / CS avoided	`40,000 × $6.50 = $260,000`	CS contact $5–8 (benchmark; modeled)	≈$0.26M
4	Expedite premium avoided	`40,000 × 40% = 16,000 re-pointed; 16,000 × $8 = $128,000`	re-pointed share and premium midpoint of the $5–12 benchmark (both illustrative)	≈$0.13M
5	Structural-stockout run-rate	`$400M × 4% = $16M lost sales; × 20% = $3.2M recovered; × 40% = $1,280,000`	illustrative retailer × lost-sales benchmark (2–6%) × −20% record × margin	≈$1.3M/yr modeled

TWO PROBES

Why act before you knew the cause?

Because waiting had an hourly price — the queue was aging while inventory sat idle — and a reversible, logged intervention did not. I checked with engineering first that manual clears could not corrupt allocation, timestamped every rebalance, and hunted the cause in parallel with alerts I had already built.

Isn't this a hero story?

The event is; the post-mortem is the point. Carrying the first stretch solo is one of my do-differentlys. What I would present as the result is the mechanism set — heartbeat, DST checklist, 3σ page rule, rehearsed playbook — and that the next peak ran boring.

Canon numbers (basis labels): 99% fill vs 95% goal (record) · ~$8M protected vs ~$6M at risk (record) · 3 DCs / 100 stores (record) · near 0.85 d vs far 4.60 d (record) · −20% structural stockouts (record) · ≈$3.2M margin at 40% (modeled). Never "$2MM baseline"; never present $8M as a saving.

NUMBERS I MUST NOT GET WRONG — canon values with basis labels NEW

Canon numbers for all seven primaries with their basis labels (S11 and S12 from the master packet's §4.1 ledger; the five new stories' rows re-cut from the program documents, with the footing mine). Say record numbers flat; say modeled numbers with their inputs; say a priced number as priced.

METRIC	VALUE TO SAY	BASIS	NEVER
S11 cost-to-serve	$0.66 → $0.03 per container (about 95%)	record	"$1.00 → $0.03"
S11 customers	7 → 68 = 9.7×; zero rollbacks; no added ops headcount	record	"10×", or any growth multiple other than 9.7×
S11 automation / accuracy	40% → 90% / 60% → 90%	record (this packet's canon; loop packet differs — do not mix)	"70% baseline"
S11 targets / timing	68 customers · 170 MAU · 32K shipments; both targets two months early	record	—
S11 direct CTS dollars	≈$50K/yr (range $30–81K; exact $30,240–$80,640)	modeled on illustrative containers/shipment	presenting it as the value — the value is scale
S11 pre-prod measurement	300 containers, ±1.6% at 95%; rollout proof 1.5 vs 6 months; ~$1.5M saved	user anchor — separate canonical	merging the $1.5M pre-production estimate with CTS
S11 review by hand	about four hours a week at its worst, by hand for months; seven frozen metrics; ±5% WoW; 15-day active rule	record	"I invented the WBR"
S12 time-to-value / effort	month 18 → month 6; 66% less engineering effort	record	—
S12 cost avoidance	~$5M, said once	record	"$5M annual cost reduction" alongside it
S12 CTS at work-item grain	−50% partner-first vs −25% operator-first; 339.5 min/shipment; 2,200 interactions	record	—
S12 partners / burn-up	48 of 53 within a month; import-side app April 2022: 11 partners / 10 countries; 55.8% → 83.2%	record	—
S12 run-rate / decomposition	≈$1.5M/yr run-rate; ≈$2.9M + ≈$1.5M ≈ $4.4M (12% under the ~$5M record)	modeled (12 eng × $20K; 20K shipments illustrative)	presenting the split as the program's figure
S12 employer	Flexport FF App export launch	record	telling it as a Sephora roadmap (loop-packet conflict)

METRIC	VALUE TO SAY	BASIS	NEVER
S11-A decomposition	22× = 6.0× (60% → 10% of containers needing a human) × 3.67× (touches per container); weekly automation 40.0% (17 Jan) → 21.9% (31 Jan 2022) is record	record inputs; decomposition mine	attributing the 22× to automation alone; any growth multiple other than 9.7×
S11-A honest denominator	active = cumulative inflow less containers 15 days past departed_terminal; 99.4% on N = 3 discarded (95% interval 44%–100%)	record decision; interval is my arithmetic	printing the three-touch week
S11-B ledger and gates	100 containers × 7 checks; 59 failing rows, 41 first failed at two hops (69.5%); 500 containers / 20 min / 99.6%	record-from-docs; my arithmetic	claiming the pilot was on time, or a number of weeks late — say "later than the first testing plan"
S11-C Crux book	79 customers · 294,581 containers · printed $185,892 = six of nine segments · nine rows = $254,952 · 3 brokers = 75.0% of containers	record-from-docs; footing mine	quoting $185,892 as "the book"; naming a keep-alive cost
S12-A Asia latency	Asia 21.19 s vs US 3.3 s = 6.42×; 45.3% of 13.92k views; overall monthly P95 8.39 → 4.68 s = −44.2%	record-from-docs; arithmetic mine	quoting 81%; subtracting P95s across sources; a dollar as savings
S12-A dollars	tail time ≈ $1.6K / yr; exposure ≈ $0.69M / yr upper bound	illustrative / modeled	calling the exposure a saving
S16-A pipeline	system accuracy 60% → 90%; parity ≤ 1% (record gate; 0.42% pass / 1.25% investigate are illustrative); about 4% sync drop; four systems → one	record (accuracy, drop, gate); examples illustrative	the alarm threshold or weeks-to-parity as record
S16-A dollars	over $100K a year priced · BRD $103,680 (30 → 6 h/wk at an assumed $90/h) · model $100,360 · realized candidate $18,720 (208 h × $90)	priced / modeled — none claimed as savings	"I saved $100K"; a monthly figure other than $10,800
S12 decomposition range	$2.85M + $1.52M = $4.4M (12% under ~$5M); range $2.9M–$6.7M; effort piece alone $1.8M–$4.5M	modeled	"the effort band contains the $5M"; $6.8M (rounded high case)
S11 pre-production set	~$1.5M pre-production estimate · n = 300 → ±1.6% · 1.5 vs 6 months	user anchor (GFiber v8 only) — kept separate, never added to cost-to-serve	saying it as program record; "E2E 85% → ~98%" (say 86% tracked, 500 containers / 20 min / 99.6%)
S11 FTE equivalent	80,000 × 3.5 touches × 1 min ÷ 1,800 h ≈ 2.6 FTE (2.4 at 1,920 h)	modeled (assumptions named)	presenting it as record headcount

Never-say, one glance before the call.

- Never "10×", or any growth multiple other than 9.7× — say 7 → 68 (9.7×).
- Never merge the ~$1.5M pre-production saving with cost-to-serve; never stretch it into a range.
- Never "$5M avoidance" and "$5M annual reduction" as two results — the avoidance is said once.
- Never "I invented the WBR" — copied from the LSA review, which was the point.
- Never claim platform configuration; program-lead voice throughout. The only personally configured platform in canon is Manhattan DOM.
- S14, S15, S10 are the bar raiser's, and S16 is his primary too — this packet's S16-A is the data-model cut only; S1/S3, S2/S18, S6/S8 belong to Lan, Goforth and Hoerger — pointers only here.

WHAT TO SAY ABOUT MY ROLE — the I-versus-we line for each story NEW

The I-versus-we rule. Say *I* for what I decided or authored — the plan, the gate, the analysis, the document, the read-out. Say *we* only for results other people delivered, and name the owner when the work was theirs. No source documents a direct report, so every people answer is program-lead voice: owners, gates and cadence — never "my team of …".

STORY	"I" — WHAT I OWNED	"WE" / THEIR WORK	NEVER SAY	EVIDENCE
S11 · wave machine	I owned the rollout: I wrote the wave plan as a schedule, published the entry bar (about fifty containers of the customer's own data) and the six graduation criteria before wave one, and ran the weekly review that gated each wave.	Nine teams (~100 people) built and operated the product; onboarding and sales sat with other teams; the VP decided the holds.	I built the platform · I ran the pilots myself · I scaled it alone	AP A1 p6–7; P4PL p1–2
S11-A · the Monday review	I built and ran the review by hand for months, froze the seven definitions with the input owners, and made the denominator honest. The dollars per ticket come from Data Services and FP&A at their loaded rates, never my own.	The input owners ran their lines; the pipeline later carried the formulas.	I set the cost per ticket · the LSA workbook's numbers are mine	AP A2 p8–10
S11-B · launch readiness	One of two technical program managers. I defined the gates and ran the go / no-go read-out; I made the 100-container run the UAT spine with a Jira ID on every missed row.	The QA team ran the container log day to day; business users ran UAT; the test lead designed the hop-by-hop trace.	I ran the test · the pilot was on time · it was N weeks late	AP A5 p13–15; PTA p1–3
S11-C · Crux transition	I owned the mitigation of the decommission risk: top of the risk register, the apples-to-apples comparison, the 79-customer base priced per segment, and the one-canonical-source rule.	The transition document's owners built the per-customer paths with me; the decision was the executive decider's (RAPID).	I decided to retire Crux · I own the revenue number	AP A4 p12–13; RAPID p1
S12 · export roadmap	I drove the sequence call: I priced both orders on shared axes and ranked the backlog by benefit × impact ÷ dev-weeks; my manager saw the math first and pressure-tested it with engineering for two days; the onsite ratified it.	Engineering did the re-estimates and the build; the 339.5-minute baseline is the program's time-and-motion analysis — I did not run the stopwatch.	I built the app · it was my idea alone · $5M a year	AP B2 p17–19
S12-A · Asia latency	I drove the follow-ups from the monthly review and kept the plan, the sequencing and the smoke tests honest.	The app engineer wrote the investigation; the network-infrastructure owner made the CDN and DNS changes (ASIA p3 names the owners).	I fixed the CDN · I found the root cause	ASIA p1–4; AP B3 p19–21
S16-A · Snowflake pipeline	I wrote the BRD, froze the seven definitions, made the Monday review the acceptance test and owned the cutover call; I own the miss — I planned the build and not the security review.	The infrastructure team built the pipeline: I didn't lay pipe, I made the pipe buildable.	I built the pipeline · I saved $100K · bus factor ≥ 2	AP A3 p10–11, G3 p45–46; BRD p1–5

Seat sources: Apple v11 chapters A1–A5, B2–B3 and G3 (the candidate's own account), the BRD, the RAPID table, the investigation document and the testing approach. Anything not in those is not said as "I".

VERIFY BEFORE YOU SAY IT — 4 specifics in no source file NEW

The first pass carried 37 yellow items. Everything the program documents, the Apple v11 workbook, the BRD or the review workbooks state was converted to a fact or a labeled anchor (see SOURCE TRACE). These are the only specifics that are in **none** of the source files. **Rule: do not say the specific — say the safe sentence beside it.**

ROUTER AND FRONT MATTER

☐ V1 a named person I mentored or developed, with an outcome — no source names one. **Safe sentence:** "I led through programs rather than a reporting line: I grew the input owners across nine teams until each signed and defended their own definition. I don't have a one-to-one mentee story I can document, so that is the one I'll give you."

S11-A

☐ V2 whether the 10- and 30-day alternatives were compared before 15 was frozen — not in any source
Safe sentence: “I froze the fifteen days with the input owners; I did not record a ten- and thirty-day comparison, and I would run one now.”

S11-C

☐ V3 how Crux handled exceptions — not in any source
Safe sentence: “I don't know how Crux handled exceptions; for the new product, a failed auto-track opened a ticket to Data Services.”

S12-A

☐ V4 whether synthetic probes were adopted — not in any source
Safe sentence: “The document raised synthetic probes as an open question; I added P50, P90 and P95 by region to the review, and I can't say whether probes were adopted.”

Left as labeled anchors, not VERIFY items. The ~$1.5M pre-production set (n = 300, 1.5 vs 6 months) and the “#3 → #14 of 16” ranking are in the candidate's own prior master only — say them as “my estimate” and “as I recorded it”; Snowflake table and column names are in no source (the BRD names the Ticket ID, the container number and Looker SQL Runner views only), so the data-model story describes the join, the grain and the artifacts and never names a table.

SOURCE TRACE — every quantitative claim in the new and modified stories NEW

Number · story · source file · page / row / sheet · match. **Y** = the source says it; **Y-with-rounding** = the source says it and I rounded or divided; **CONFLICT** = sources disagree — say the safe wording; **UNSUPPORTED-anchor** = only my own prior master or my own model — say it as “my estimate / my model”. Apple page = PDF page of the v11 workbook.

AP Apple_PMIII_Interview_Stories_v11_2026-08-26 (PDF page; chapter in brackets) · **BRD** BRD_-_SV_Zendesk_Data_in_Snowflake · **TPM** Technology_Program_Management_Status_Week_of_November_19th__2021 · **PCRS** SV_-_Pilot_Client_Roll-out_Schedule · **PTA** SV_-_Product_Testing_Approach · **P3PL** Shipment_Visibility_3PL_ingestion-_One_Pager · **P4PL** Path_to_4PL__Visibility__Rajesh · **WBRAI** WBR_Metric_Culture_using_AI · **LSA** LSA_WBR_2022 workbook (the .CSV upload is an .xlsx; sheet and Excel row given) · **C100** 100_Container_Debugging_Session_-_Basic_test_cases (.csv; my recount of the working log) · **RAPID** RAPID_-_Crux_Customer_Transition · **ASIA** FF_App_Asia_Latency_Investigation · **HLSD** High-Level_Solution_Document_FF_App__Schedules · **GF8** GFiber_MASTER_Packet_v8 (the candidate's own prior master — a user anchor, not a program document) · **RECON** numbers-reconciliation.md (CANON v2 ledger and §2 tables)

#	NUMBER / CLAIM	STORY	SOURCE FILE	PAGE / ROW / SHEET	MATCH
1	7 → 68 customers; 9.7× (68 / 7 = 9.71)	S11	AP [A1]; WBRAI	AP p6–7; WBRAI p1–2	Y-with-rounding

INTERVIEW-PREP PACKET 1 OF 5 · ADD-ON · FOUR DESIGN CASES FROM THE GOOGLE FIBER (GFIBER) PACKET

Amazon NACF Supply Chain loop — Packet 1 add-on: Snigdha Tripathy

Amazon — Senior Supply Chain Manager, NACF Supply Chain (L6) · four full design stories: E1 · E3 · E9 · E11

Snigdha Tripathy

Senior Manager, Supply Chain — NACF Supply Chain · HIRING MANAGER

Wednesday, October 29, 2026 · 10:00 am PDT · 55-minute video interview

COMPANION TO: AMAZON-NACF-PANEL-1-TRIPATHY-KIMI-K3 (THE SEVEN FLEXPORT PRIMARIES). NOTHING IN THAT PACKET CHANGES; THIS ADD-ON STANDS ALONE.

DESIGN CASE — say "I designed"; numbers marked illustrative / modeled / record per basis label. This banner repeats on every story. None of the four is a delivered result.

Why this add-on exists. Her public profile (public-profile inference, labeled as such in the main packet) says she will test whether mechanisms transfer to her world: inventory placement across a network, inbound lead times and capacity, readiness for 50+ launches, standard work and root cause. The four design cases map one-to-one onto that: **E1** field / truck-stock inventory — positioning and replenishment (maps to FC placement); **E3** vendor EDI + VMI for long-lead equipment — inbound planning and lead times (maps to inbound capacity); **E9** ERP cutover from a legacy WMS — tolerance, mocks, freeze, one promise publisher (maps to FC launch readiness); **E11** direct procurement of long-lead equipment — PO lifecycle, confirmations, ranked expediting (maps to inbound expedite and prioritization). Each is a full primary, built at finished-goods grain, with the same anatomy as the Flexport primaries: pitch, situation / task, five gated phases, basis-labeled results, L6 evidence, five labeled facets, four-table math, a four-question behavioral pack, three angle cards and three trap drills.

How to say it: every story below is a **design case**. Open with "I designed…" or "Here is how I would run it…". Where a lived record sits underneath (Sephora cutover, Elementum EDI lanes and lead-time distributions, Flexport gates) it is named separately and labeled **record**; the design numbers are **illustrative** or **modeled**, never delivered outcomes.

Canon: amazon/amazon-l6-scm-master-packet.html (E1 / E3 / E9 / E11, §3.0); origin: GFiber_MASTER_Packet_v8 Part 3 prompts D1 / D3 / D9 / D11; record numbers: Apple PMIII v11 and NUMBERS-RECON §3 (CANON v2). Every dollar carries its basis label.

INTERVIEW-PREP PACKET 2 OF 5 · PER-INTERVIEWER · BUSINESS-PROCESS LENS

Amazon NACF Supply Chain loop — Packet 2: Ryan Hoerger

Amazon — Senior Supply Chain Manager, NACF Supply Chain (L6)

Ryan Hoerger

Manager, Placement Analytics — NACF Supply Chain

Wednesday, October 29, 2026 · 12:00 pm PDT · 55-minute video interview

SHADOW INTERVIEWER: SANDY HSIAO (A SECOND NOTE-TAKER — SAME PACE, SAME NUMBERS; EXPECT ONE QUESTION FROM THE SHADOW NEAR THE END)

Strategy in one line. The most quantitative interviewer on the panel gets the Elementum stories as primaries — ten, each with a real analytical spine (distribution, sample size, interval, counterfactual, sensitivity) and substituted worked numbers. Lead with S8 (measured lanes → p99 promise → ~$1.5M of inventory carrying cost released, zero stockouts) or S6 (honest supply → shortage alert a lead-time early → $2M released under a two-signal rule); go deeper with S8a (the distribution analysis), S8b (the safety-stock formula redesign), S8c (the back-test) and S9 (1,000 lanes → 597); reach for the Walmart Marketplace delivery-experience DESIGN CASES (S19, S20, S21 — prep models, never delivered results; the lived companion is S8/Apple F4) and the new-market newsvendor design (E7) as the second and third examples. The two lane programs' dollars never meet. In his language: S6 positions safety stock where measured errors justify it; S8 positions the promise at p99 per lane. Every dollar keeps its basis word — record · user anchor · modeled · illustrative.

LP focus — my guess, not confirmed: Dive Deep · Are Right, A Lot · Learn & Be Curious — with a mentorship angle (his public About line names "a culture of mentorship"; expect one people question). Amazon does not disclose the assignment; the guesses are reasoned from the interviewer's title, the JD and his public profile in "Read me first" (public-profile inference, labeled as such) and should be held loosely — Insist on the Highest Standards remains a live alternate via the 99% bar in S8.

Shadow etiquette: address both; the shadow is usually a new interviewer being calibrated — same numbers, same pace; if the shadow asks the last question, answer it with the same discipline (phase asked, then stop).

Canon: amazon/amazon-l6-scm-master-packet.html (§1.2 roster, §4.1 ledger). Every number below is that packet's value; every dollar carries its basis label (record · user anchor · modeled · priced).

Contents NEW — existing sections kept; red NEW pills mark what this upgrade added; teal ELEVATED marks an existing story that gained sections

FRONT MATTER

A	5-minute cram sheet — profile hooks, ten stories in order, three opening sentences, five numbers NEW	3
B	Question → story router — all 16 Leadership Principles and the common non-LP prompts NEW	4
	Read me first — the interviewer's lens, guessed LPs, answer strategy (existing)	6

PRIMARY STORIES — EACH: LPS · 20-SECOND VERSION · PITCH · S/T · ACTION · RESULTS · L6 · FIVE FACETS · PROBING + FOUR-TABLE MATH · BEHAVIORAL PACK · THREE ANGLES · TRAP DRILLS

S6	Elementum — one real-time supply/demand view: shortage a lead-time early; 70% → 85%; $2M released (existing, elevated) ELEVATED	9
S8	Elementum — measured lane distributions: p99 promise on 200 lanes; 580K units / ~$1.5M of carrying cost released, zero stockouts (existing, elevated) ELEVATED	21
S8a	Elementum — actual-vs-planned lead-time distribution analysis: p50 / p90 / p99, how the brochure was wrong NEW	32
S8b	Elementum — safety-stock formula redesign: service-level z, two honest terms, one lane released and one lane topped up NEW	41
S8c	Elementum — validation and back-test design: out of sample, not a quiet quarter NEW	49
S9	Elementum — a thousand lanes asked, 597 first (user anchor): spend Pareto, ≥95% ASN gate, completeness 60% → 95% (record) NEW	57
S19	DESIGN CASE · Walmart Marketplace — the delivery promise: one governed buffer dial; fast-promise share 7.6% → 39.6% (in the model) NEW	68
S20	DESIGN CASE · Walmart Marketplace — the pre-purchase delivery WBR: factor math and an Andon (in the model) NEW	80
S21	DESIGN CASE · Walmart Marketplace — the managed-shipping program: incentive diagnosis, contract, shadow gate (in the model) NEW	92
E7	Elementum design engagement (new-market build) — equipment forecast-to-buy: newsvendor, pooling, re-forecast trigger NEW	104

BACK MATTER

	Question bank — likely questions with a one-line answer plan (extended) EXTENDED	112
	Cheat-numbers box — canon values with basis labels (extended) EXTENDED	114
	Backup bench — S4, S7 and the FFA micro-story (S9 is now a primary)	116
H1	VERIFY BEFORE YOU SAY IT — the checklist NEW	125
H2	NUMBERS I MUST NOT GET WRONG — canon values with basis labels NEW	126

How to use this packet in 90 seconds. Page A is the cram sheet. Page B routes any question to a story, an angle, a 15-second opener and one number. Every primary has four behavioral questions, three angle cards and three trap drills — the trap drills are the statistical follow-ups this interviewer is most likely to throw. Anything tagged VERIFY-WITH-RAJESH is a detail that is not in the record: confirm it or leave it out; the one-page checklist near the back collects them all.

A · 5-minute cram sheet — Ryan Hoerger, Placement Analytics NEW

WHO IS IN THE ROOM (PUBLIC-PROFILE INFERENCE — FRAMING ONLY, NEVER QUOTED BACK)

- Manager, Transfer/Placement Analytics; Chicago Booth MBA (Siebel Scholar); analytics manager at Nike; Cornerstone Research before that — expert-grade statistical work. Shadow: Sandy Hsiao (same numbers, same pace).
- **Expect:** definitions and denominators ("how was it measured?"), n and intervals, the counterfactual ("how do you know it was you and not seasonality?"), and "what is your softest input?"
- **Style:** claim → number with its basis word → stop. Memo-like, not a wind-up.

THREE SENTENCES TO OPEN WITH

> "Every dollar I give you carries its basis — record, modeled or illustrative — in the same breath, and I will tell you the n behind every percentage."

> "The planning parameter was wrong before the policy was: the brochure lead time on 200 lanes, and what counted as supply — I measured the first lane by lane and defined the second before any screen existed."

> "I owned the definitions, the policy and the release rule; planners owned the forecast and the buffers, the data team built the distributions, Finance signed each release."

THE TEN STORIES IN THE ORDER I REACH FOR THEM — THE SINGLE NUMBER EACH ONE LANDS

#	STORY	REACH FOR IT WHEN HE ASKS…	ONE NUMBER (BASIS)
1	**S8**	Used data to change an inventory policy · went deeper than the request	580K units / ~$1.5M of carrying cost released, zero stockouts (record — Apple F4; one-time, never annualized)
2	**S6**	Improved forecast accuracy · needed Finance and Planning buy-in	70% → 85%; $2M released (record, one-time)
3	**S8a**	Dug into the data · data contradicted belief	plan 18 d vs actual mean 21 d, p99 34 d (illustrative lane)
4	**S8c**	How did you validate? · how do you know it was not seasonality?	held-out quarter 99.1%, Wilson [98.7, 99.4] (illustrative inputs)
5	**S8b**	How do you set safety stock? · simplified · backbone	lane A 12,937 → 8,102 units; lane B +1,383 (illustrative)
6	**S9**	Prioritized 1,000 items · held a quality bar · pushed back upward	a thousand lanes asked, 597 first = 80% of spend (user anchor); completeness 60% → 95% (record)
7	**S19**	A metric hid the problem · simplified a decision	fast-promise share 7.6% → 39.6% at the held 95% floor (design case — in the model)
8	**S20**	Took ownership of an un-owned number · built something to act faster	Promise Yield 41.5% = 43.6% × 95.2%; ~30 d → < 24 h (design)
9	**S21**	Why a program stalled · precise about what was mine	≈$3.7M/yr per +10 pts of enrolled GMV (modeled)
10	**E7**	Decision with little data · learned a new method	critical ratio 0.99 → z 2.33 → first buy 9,495 on a 6,000 mean (illustrative; design)

FIVE NUMBERS NEVER TO GET WRONG

- **580K units / ~$1.5M of carrying cost released** — S8, record (Apple F4 says "carrying cost released" — use that noun), one-time, zero stockouts; $2.59/unit is derived. Never merged with the $2M into a range; never per year.
- **$2M** — S6, record, one-time; a different program — never added to the $1.5M.
- **A thousand lanes were asked; 597 first = 80% of spend** (user anchor — GFiber v8 only; Apple F1 and the resume say a thousand lanes onboarded across 25 European locations, so confirm what went live); completeness 60% → 95% — record. Freight −10% ≈ $2M of freight spend is a six-month user anchor, never annualized. Never say "400+ lanes."

STATISTICAL REFLEXES (SAY THESE WITHOUT BEING ASKED)

- Give n and the interval: 22 late of 2,500 → 99.1%, Wilson [98.7, 99.4] — illustrative inputs.
- One held-out quarter is one draw; rolling origin is the upgrade. Zero stockouts bounds the rate: 0 in 1,950 lane-weeks → below 0.154% (rule of three).
- Name the softest input before he does.
- **NACF bridge:** inbound lead-time variability and the definition of supply sit under every WOC target and every placement promise — booklet INV-A (WOC), INV-B (safety stock), INV-C (placement).

- **99% lead-time accuracy at the p99 promise on 200 lanes** — record; know which definition (coverage or ratio) before quoting a tolerance.
- **Six sites** — no regional qualifier; S19's ≈$13.3M/yr and S21's ≈$3.7M/yr are *modeled*, never record.

B · Question → story router NEW

How to use. Find the LP or prompt on the left, open with the 15-second sentence, land the one number with its basis word, stop. "Q#" is the behavioral question inside that story's own pack (a separate 90-second STAR from a different moment of the story). Shaded cells are honest stretches — no formal people-development story in this packet, and I will not borrow another interviewer's.

IF ASKED ABOUT…	PRIMARY STORY · ANGLE (BEHAVIORAL Q#)	BACKUP	15-SECOND OPENER	ONE NUMBER (BASIS)
Customer Obsession	S19 · Q3 — pin accuracy at 95% on every cohort; let speed float	S8 · Q2 — the customer was the production line	"Fast-promise share can be juiced by bleeding accuracy, so I pinned accuracy at 95% on every cohort and let speed float."	**Fast-promise 7.6% → 39.6% at the held 95% floor (design case — in the model)**
Ownership	S20 · Q2 — promise accuracy was owned by nobody between Tuesdays	S8 · Q4 — a promise policy planning now owns	"The one number the customer feels — promise accuracy — was owned by nobody between Tuesdays, so I took it and gave every factor a named owner."	**7 outputs over 10 inputs; Promise Yield 41.5% = 43.6% × 95.2%**
Invent and Simplify	S8b · Q1 — a formula nobody could defend plus a week of pad → two readable terms	S19 · Q2 — one dial b = k·σ instead of per-lane learned buffers	"Safety stock was a formula nobody could defend plus a week of pad nobody could count; I replaced both with two terms a planner could read."	**Lane A 12,937 → 8,102 units (illustrative); k = 1.645**
Are Right, A Lot	S8c · Q1 — held a quarter out before releasing 580K units	S8a · Q2 — the scans said 21 days, the plan said 18	"A plan fitted to history always looks perfect on that history, so before I released anything I held a quarter out."	**Held-out 99.1% vs 96.5% for a bell-curve plan (illustrative inputs)**
Learn and Be Curious	E7 · Q1 — the newsvendor model from MIT coursework on a launch problem, labeled toolkit	S8c · Q4 — shadow-mode the drift flags before go-live	"I took the newsvendor model from my MIT MicroMasters coursework and applied it to a launch problem — and I label it as the toolkit."	**CR 0.99 → z 2.33 → first buy 9,495 on a 6,000 mean (illustrative)**
Hire and Develop the Best	No packet primary — honest stretch; closest: the S6 hand-over (planners run the alert and the measurement without me)	S8 · Q4 — planning re-applies the release rule on its own cadence	"I have no formal mentoring story here; the nearest true one is that planners now run the alert, and domain owners the gates, without me. VERIFY-WITH-RAJESH"	**Planner collaboration +50% (record, Apple F3)**
Insist on the Highest Standards	S9 · Q2 — the ≥95% valid-ASN gate failed twice and was held twice	S8c · Q2 — 99% per lane, no pooling	"A cohort failed our ≥95% valid-ASN gate twice on a carrier timestamp format, and I held the gate both times."	**Completeness 60% → 95% behind a ≥95% gate (record)**
Think Big	E7 · Q2 — a launch chain designed as the template for market N+1	S6 — eight data domains, one view across six sites	"I designed the launch chain as a template for market N+1, not a one-off for market N."	**One chain · three books of record · five invariants (design, not run)**
Bias for Action	S20 · Q4 — an Andon that acts in 24 hours instead of a 30-day scorecard	S6 · Q3 — alert live in three months	"A 30-day rolling scorecard lets a degrading seller or carrier burn customers for weeks; I designed a control that acts inside 24 hours."	**~30 days → < 24 hours (design); false-trip bar < 5%**
Frugality	S8b · Q3 — less stock and better service	S8 — the release itself, with the watch armed first	"Less stock and better service — on one lane, 37% fewer units and seven late shipments in a hundred became one."	**580K units / ~$1.5M net, zero stockouts (record, one-time)**
Earn Trust	S6 · Q2 — the two-signal rule signed before the first release	S8c · Q3 / S21 · Q3 — say what the test cannot show; say what was mine	"Releasing $2M of safety stock is a risk Finance and Planning both carry, so the rule was theirs before it was mine."	**$2M released (record, one-time); both-errors rule**
Dive Deep	S8a · Q1 — 400 scans on the busiest lane: 21 days actual against 18 planned	S20 · Q1 — 97% national, 82% in the Southeast: the factor math names the cell	"Buffers kept growing and nobody could say why, so I pulled the shipment scans on our busiest lane — about 400 shipments, planned date against actual receipt."	**Mean 21 d vs plan 18 d; 240 of 400 (60%) slower than the brochure (illustrative lane)**
Have Backbone; Disagree and Commit	S9 · Q1 — told the Global Head that 1,000 lanes in two months means confident wrong data	S8b · Q2 — a rule that can add stock, not just release it	"The Global Head of Supply Chain wanted 1,000 lanes of inbound visibility in two months; I told him the schedule would deliver confident wrong data and showed him the spend curve instead."	**597 lanes = 80% of spend first; the remainder (~20% of spend) deferred behind the same gate (user anchor)**
Deliver Results	S6 · Q3 — a shortage visible a lead-time early, in three months	S9 — completeness 60% → 95% (record); freight −10% ≈ $2M of freight spend in six months (user anchor)	"Three months from kickoff, a planner could see a shortage a lead time before the line stopped."	**70% → 85% forecast accuracy; $2M one-time (record)**
Strive to be Earth's Best Employer	No packet primary — honest stretch; closest: S6 planner collaboration +50% once the private spreadsheets died (Apple F3)	S8 — the drift flag and refresh cadence handed to planning	"I will not dress up a story I do not have; what is true is that the work moved off the planners' week into root-causing. VERIFY-WITH-RAJESH"	**Planner collaboration +50% (record, Apple F3)**

IF ASKED ABOUT…	PRIMARY STORY · ANGLE (BEHAVIORAL Q#)	BACKUP	15-SECOND OPENER	ONE NUMBER (BASIS)
Success and Scale Bring Broad Responsibility	S9 · Q4 — carriers without EDI would have been priced out; the standard became the data, not the transport	S20 — an Andon with a < 5% false-trip bar so a seller is not penalized on noise	“Carriers without EDI would have been priced out of the standard, so I made the standard the data, not the transport.”	**Adoption 8× (user anchor — GFiber v8 only); XML/portal floor**

COMMON PROMPTS THAT NAME NO LEADERSHIP PRINCIPLE — AND THE STATISTICAL PROMPTS HE IS MOST LIKELY TO ASK

COMMON PROMPT	PRIMARY · ANGLE	BACKUP	ONE NUMBER
Tell me about a time you failed	S4 (bench) — the in-transit promise rule I got wrong, fixed through the signed policy	S6 angle (iii) — MPN worklist gated longer than planned · S9 angle (iii) — the gate failed twice	**Lane σ ≈ 0.3 d; ~0.49-day window ≈ 95% (record promise math)**
…disagreed with your manager	S9 · Q1 — the Global Head, two levels above my sponsor (a client leader)	S8b · Q2 — release-only rule vs add-stock clause	**597 lanes = 80% of spend**
…influenced without authority	S8 — Finance signed each lane; none reported to me	S21 — contract design across seller, marketplace, carrier	**580K units / ~$1.5M (record)**
…reduced cost	S9 — freight −10% ≈ $2M of freight spend in six months (user anchor, not annualized)	S8b — inventory capital, 580K units / ~$1.5M	**$2M in six months; ≈$0.4M/yr doc labor modeled**
…dealt with ambiguity	S8 — a "variability report" request reframed as a parameter problem	E7 — a launch with no local history	**200 lanes scoped by site, lane and mode**
…simplified a process	S19 — one governed dial instead of per-lane learned buffers	S8b — two terms; S20 — 7 outputs over 10 inputs	**k = 1.645; 7.6% → 39.6%**
…decided with incomplete data	E7 — newsvendor on no history; the critical ratio sets the quantile	S8a — thin lanes print their interval	**CR 0.99; z 2.33; trigger ±20% over two weeks**
…missed a deadline	S6 — MPN worklist gated longer; re-sequenced date with the coverage number	S9 — gate held twice; schedule moved, not the bar	**Alert live in 3 months (record)**
…mentored someone	Honest stretch — S6 owners take over gates and root-cause reviews VERIFY-WITH-RAJESH	S8 — planning owns the refresh cadence	**Planner collaboration +50% (record, Apple F3)**
…delivered under a tight timeline	S6 — three months to a live shortage alert	S9 — 1,000 in two months became 597 in month one	**Alert in 3 months; 597 lanes live month one**
…changed your mind with data	S8b angle (iii) — the textbook form was my starting point; one skewed lane showed it understates the tail VERIFY-WITH-RAJESH	S21 angle (iii) — the funnel said awareness; interviews showed an unpriced trade VERIFY-WITH-RAJESH	**normal p99 30.3 d vs ranked 34 d; release 8,009 vs 4,835 (illustrative lane)**
How would you set safety stock / service level?	S8b — two terms; critical ratio; lane A and lane B	S19 — one dial b = k·σ at a 95% floor	**SS 12,937 → 8,102 (illustrative)**
How do you validate / back-test a policy?	S8c — held-out quarter, paired replay, interval, rule of three	S21 — shadow gate before day one	**99.1% [98.7, 99.4]; 0 in 1,950 → < 0.154%**
MAPE vs bias · alert thresholds · false alarms	S6 — alert at lane p90; precision/recall; cost of a false alarm	S20 — Andon false-trip bar < 5%	**p90: precision 71.2%, recall 98.6% (illustrative lane)**
Lead-time variability — how do you measure it?	S8a — p50 / p90 / p99, empirical not bell-curve	S8 — per-lane distribution, drift flag	**plan 18 d vs mean 21 d, p99 34 d**
New market / placement with no history	E7 — newsvendor + risk pooling + re-forecast trigger; NACF INV-C	S19 — promise at the tail you can defend	**Q = 9,495 on a 6,000 mean (illustrative)**
Prioritize 1,000 items	S9 — spend Pareto, four-factor score, 597 first	S8a — which lanes are thin	**597 = 80% of spend**
Metrics architecture / WBR · promise policy · incentives	S20 · S19 · S21 respectively	S6 — metrics tree	**Promise Yield 41.5%; 7.6% → 39.6%; ≈$3.7M/yr per +10 pts (modeled)**
Your statistical background?	MIT SCM MicroMasters toolkit, labeled; S8a / S8c are the interval work	Never "I build models for a living"	**Toolkit, not job title**

Read me first

The interviewer's lens (inference from title, JD and public profile — the profile parts labeled)

Inference from the title. "Placement Analytics" is the analytical arm of inventory placement — deciding where inventory should sit in the network so that the promise holds at the lowest landed cost. A manager in that function lives on forecast error, lead-time variability, safety-stock policy, service levels and the data-quality underneath them. He will be the most quantitative interviewer on the panel and the most likely to ask "how was that measured?", "what was the denominator?", and "what is the softest input in your model?" He is also the one most likely to recognise a textbook formula being passed off as a program artifact — so the honesty labels matter more here than anywhere.

What that means for the answers. Ten Elementum primaries (the router and cram sheet say which to reach for). The first two are the Plan-process redesigns with the math visible: the shortage-alert / real-time supply-demand view (S6 — forecast accuracy 70 → 85%, $2M safety stock released under a two-signal rule) and the measured-lane lead-time program (S8 — promise at p99 on 200 lanes, 580K units / ~$1.5M of carrying cost released with zero stockouts). The other eight are the same facts cut for a statistician — the lead-time distribution (S8a), the safety-stock formula (S8b), the back-test (S8c), the 1,000 → 597 lane prioritization (S9), the Walmart Marketplace delivery promise, WBR and managed-shipping DESIGN CASES (S19, S20, S21 — in the model, never delivered) and the new-market newsvendor design (E7). The lane programs end on *capital released on evidence with service held* — asset utilization and reliability in the JD's words. Keep the two programs' dollars apart in every sentence. A shadow (Sandy Hsiao) is on the call: same pace, same numbers, expect one question from the shadow near the end.

What his public profile adds (public-profile inference, labeled)

The profile (public-profile inference — directional, not verified biography). Manager, Transfer/Placement Analytics at Amazon (Jul 2025–), New York; before that Senior Business Intelligence Engineer at Amazon (Dec 2024–Jul 2025); analytics manager at Nike (2021–24); analyst at Cornerstone Research (2016–20) — an economics-consulting shop where the work product is expert-testimony-grade statistical and financial analysis; Chicago Booth MBA (Siebel Scholar); Duke. His own About line: "rigorous statistical and financial analysis… a blend of data analysis and writing skills… a culture of mentorship." **Quoted for framing only — never referenced in the room; none of it enters my stories.**

What that means for the answers. Expect *definition-level probing*: MAPE versus bias and which one steered; the grain (SKU-family? per lane?); the window and refresh; what "99% lead-time accuracy" tolerates in days. Three such definition Q&A are drilled into the S6/S8 probing below. Second, *answer style: crisp and memo-like* — claim, evidence, stop; he writes for a living, and a long wind-up reads as evasion. Third, speak *placement*: S6 is positioning safety stock where the measured errors justify it; S8 is positioning the promise at p99 per lane — his daily work is deciding where inventory sits versus where it is promised. Fourth, the mentorship line in his About suggests one people probe — answer it with planners grown into owners (S6's measurement handover; S8's drift flag owned by planning), not with org charts.

Three guessed LP focus areas, with rationale

> **Labeled guess.** Amazon assigns 2–3 Leadership Principles per interviewer and does not disclose them. These three are inferred from the title, the JD and the public profile above (public-profile inference); if the first question lands on a different LP — Insist on the Highest Standards via the 99% bar, or Frugality via the capital releases — the twist maps under each story carry the pivot.

GUESSED LP	WHY THIS INTERVIEWER WOULD CARRY IT	STORY TO OPEN · BACKUP
Dive Deep	An analytics manager tests whether the candidate goes to the data grain — measured lane distributions instead of brochure values; the definition of "supply" before any screen. S8 is the Dive Deep primary in the master map.	S8 (open) · S6 (the supply definition, the MAPE/bias measurement)
Are Right, A Lot	Placement decisions are judgment under uncertainty; he will probe how the candidate was right against the room's belief and how the decision was made safe (release rule, watch window, fat-tail exception).	S8 (measured vs brochure; p99 chosen by planning on the asymmetry) · backup: S6 (refusing unfirmed MRP orders as supply)
Learn & Be Curious (with a mentorship angle)	A Cornerstone-trained analyst with a Booth MBA who writes about rigor and mentorship (public-profile inference) will test whether the candidate learns at the definition level and grows people at the mechanism level: the MIT toolkit acquired to design what I had been implementing — labeled toolkit, never day job — and planners grown into owners of the measurement, the drift flag and the refresh cadence. Insist on the Highest Standards stays live as the 99% bar before any release and the two-signal rule before any buffer came out.	S8 (99% bar; drift flag owned by planning) · S6 (measurement handed to planners)

Answer strategy — business first, systems as enablers

- **Open with the process problem and its cost, not the system.** First sentence names the broken process (Plan, Source, Make, Deliver or Return), who it hurt (customer, Finance, the floor) and the baseline number. The platform appears only as the enabler of the redesign, in one clause.
- **Use the JD's four outcome words as the results frame:** reliability (did the promise hold?), responsiveness (how much earlier did we see it?), cost efficiency ($ with its basis label), asset utilization (capital, labor-hours, capacity released).
- **Action = operating-model redesign in gated phases** — Discovery → Plan & Design → Build & Test → Cutover → Hypercare, each spoken as entry bar · what I delivered · exit bar. Say the gate that fired, not the meeting that happened.
- **Every dollar carries its basis word in the same breath** — record · user anchor · modeled · priced. A record dollar is said flat; a modeled dollar is said with its inputs. Never promote a modeled number to record.
- **Program-lead voice.** I owned definitions, rules, gates and the signature chain; engineers, SIs and vendor teams configured and built to the spec I signed. The only platform personally configured in canon is Manhattan DOM.
- **The pitch ends on the primary metric.** Then stop. Silence after the pitch is the interviewer filling their STAR worksheet; their probes are the second half of the answer.
- **For Placement Analytics specifically:** lead with the planning parameter that was wrong (brochure lead time; unfirmed orders counted as supply), the decision it corrupted (buffer size, shortage response), and the rule that released capital safely. Show one formula only when asked, labeled as the MIT toolkit illustration — the data team built the distributions; planners sized the buffers; Finance signed.
- **Answer style for this room: crisp, memo-like.** Claim, evidence, stop. His background (Cornerstone rigor; a writing-heavy About line — public-profile inference) means a long wind-up reads as evasion; the one-breath basis label ("record", or "modeled, on illustrative inputs") does more credibility work here than any extra sentence.
- **Speak placement.** Frame S6 as positioning safety stock — buffer placed only where measured forecast and lead-time errors justify it — and S8 as positioning the promise at p99 per lane, recomputed on a drift flag. His

team decides where inventory sits versus where it is promised (public-profile inference); that is the exact shape of both stories.

- **Keep S6 and S8 apart:** $2M (S6, forecast-driven, two-signal rule) and ~$1.5M / 580K units (S8, lead-time-driven, 99% bar) are different programs — never add them, never swap their mechanisms. "Six sites" — never "six NA sites"; never paste S6's "3 months" onto the six-site ingest (that is S7, not in this packet).

Loop-consistency rule. One question, one story; never the same story to two interviewers — interviewers compare notes. Held for other packets (do not spend here): S11/S12 (Tripathy) · S2/S18 (Goforth) · S1/S3 (Lan) · S16/S15/S10/S14 (Josyula). S7 (CM BOM) is an unallocated master-packet backup — pointer only, and no BOM-explosion content. S9, S19, S20, S21 and E7 are used here as primaries: if the same story is also drafted for another interviewer, tell it in one room only. If pushed for "another example" on an LP, use the named backup in the question bank or the backup bench at the end of this packet, never a story allocated to another interviewer.

How to read the "L6 level evidence" block under each story. Amazon's L6 functional bar (user-supplied rubric): *Ambiguity* — strategy or network undefined; I select the stakeholders, set the goals, deliver independently. *Scope & influence* — team-level scope; influences one to two levels up. *Execution* — tactical and strategic; simplifies or extends; applies best practices; force-multiplies; mitigates long-term risk; makes the short-versus-long-term trade-off explicit. *Impact* — long-term team goals. *Process improvement* — operational-excellence best practices institutionalized. *Complex* — visible risks, roadblocks and constraints mitigated through expertise, judgment and influence to consensus. Overview themes the block is tuned to: designing and modeling the supply chain rather than working in it; developing new processes for others to own; root-cause mechanisms that resolve trending issues at scale; recommendations to leadership that outline competing metrics. The block sits right after Results so the evidence is on the page when the probing starts.

The stories — business-first, canon numbers

Ten Elementum primaries from the same six-site manufacturer, three Walmart Marketplace DESIGN CASES (S19–S21 — built from my own interview-prep models, never delivered; lived companion: Apple F4 / S8) and a new-market design engagement (E7). Each primary: LPs carried · 20-second version · 60-second pitch → Situation/Task → Action in gated phases → Results → L6 evidence → the five facets → Probing with the four-table math → behavioral pack (four separate 90-second answers) → three angles → three trap drills. S6 and S8 are the existing stories, elevated; the other eight are new to this packet (red NEW pills mark every new section).

S6 — Elementum — one real-time supply/demand view across about eight data domains: a shortage visible a lead-time early, forecast accuracy 70% → 85%, $2M of safety stock released under a two-signal rule ELEVATED

LPs this story can serve here: Dive Deep (the definition of supply; MAPE/bias at the decision grain) · Earn Trust (the two-signal release rule signed with Planning and Finance) · Deliver Results (third — alert live in 3 months) · Think Big (one view over eight domains) · Are Right, A Lot (backup — refusing unfirmed orders as supply)
Process family: Plan — S&OP / shortage management / safety-stock policy; data-integrity program behind the plan

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH NEW

- **Dive Deep** — I profiled every domain and defined supply honestly before any screen — released planned orders only, because unfirmed MRP orders breathe every run.
- **Earn Trust** — The $2M left the buffer only under a both-errors-improved rule Planning and Finance signed — the exception was written in before anyone asked.
- **Deliver Results** — Forecast accuracy 70% → 85% on scoped class-A SKUs; the shortage alert live in three months; planner collaboration up 50% once the spreadsheets died (Apple F3).
- **Ownership** — Nobody owned the seam between about eight data domains (user anchor) and the planners — I took the definitions, the data-integrity program and the delivery.

Honesty label. I owned the definitions, the data-integrity program and the delivery; the client's SAP teams and our integration engineers built the feeds; planners owned the forecast — I owned its measurement and the release rule. I have not owned a demand forecast end-to-end and won't claim it. The safety-stock formula is how I explain it now with the MIT toolkit — an illustration, not a program artifact.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. A six-site manufacturer — mixed make-to-order and make-to-stock — learned about a component shortage when the line stopped. S&OP ran off private spreadsheets, shipment data was incomplete, and supplier, material, BOM, inventory, production, transportation, sales-order and planning data lived in SAP and site systems but never met. Leadership's question — which customer orders are at risk this quarter? — had no data path, so the plan responded with expedites instead of re-plans and buffers sized on noise. **Task.** Nobody owned the seam; I took the definitions, the data-integrity program and the delivery. **Action.** I defined supply honestly before any screen — on-hand plus production plan plus released planned orders only, at SKU × location × date — and refused to count unfirmed MRP orders because they change every run. Domains went live in waves sequenced by planner trust, each behind a published data-quality gate, with daily reconciliation to the SAP source and false alarms worked as defects. The shortage alert fires when days-of-cover falls to the lane's measured p90 lead time — the last moment a re-plan is cheaper than a flight. Safety stock came out only under a rule Planning and Finance signed: release where forecast error and lead-time error had both improved. **Result.** Primary metric: forecast accuracy on the scoped class-A SKUs 70% → 85%. $2M of safety stock released under the two-signal rule — record, one-time working capital — with ≈$0.8M a year of modeled recurring value around it; the shortage alert live in three months; planner collaboration up 50% (Apple F3 — not “effort down 50%”). That $2M is a different program from the lane program's $1.5M; I never add them.

20-SECOND VERSION NEW

Eight data domains, one honest definition of supply, a shortage alert that fires when days-of-cover falls to the lane’s p90 lead time — a lead-time early — and $2M of safety stock released only where forecast error and lead-time error had both improved.

NACF BRIDGE — ONE SENTENCE

This is the NACF WOC loop: define supply honestly, alert at the last moment a re-plan is cheaper than an expedite, and cut weeks of cover only where both error signals have improved — INV-A and INV-B in the inbound booklet.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — A strategic manufacturing customer with six sites: planners learned about a component shortage when the line stopped; S&OP ran off private spreadsheets; shipment data was incomplete; about eight data domains (user anchor) lived in SAP and site systems but never met. Leadership's question — "which customer orders are at risk this quarter?" — had no data path.

The Plan process underneath was running on an unsafe definition of supply (unfirmed MRP orders counted because they looked better), an unmeasured lead-time error, and a shortage signal that arrived at line-down. The cost: expedites instead of re-plans, buffers sized on noise, and planners spending ~40% of their week reconciling rather than root-causing.

T — Nobody owned the seam — no spec, no agreed grain, no definition of "supply," no data-quality bar. I chose all four, as owner of the definitions, the data-integrity program and the delivery. Goal: a real-time supply/demand view with honest definitions and a shortage visible a lead-time early — and planner trust, which was the real product.

Baselines on the table: forecast accuracy 70% on scoped class-A SKUs · shortage detected at line-down (target: a lead-time early) · shipment-data completeness 60% · planner effort on reconciliation and firefighting (≈40% of the week, illustrative share; the −50% is record).

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery (4–6 wks)** — profiled every domain (completeness, latency, joinability) to my own gap templates; wrote the definitions memo — grain SKU × location × date; supply = on-hand + production plan + released planned orders only — and the metrics tree (OTIF, inventory $, MAPE/bias, lane lead-time accuracy, completeness, latency, adoption).

Refused Planning's request to count unfirmed MRP orders as supply. *Exit bar:* signed gap findings per domain; scope frozen in writing; planners agree the supply definition before any screen.

- **Plan & Design (parallel)** — master-data foundation plan; MPN mapping worklist with its coverage gate; domain-wave sequence by trust; DQ scorecard spec; the 10-step onboarding playbook. *Exit bar:* master-data gates green; unmapped-MPN list under threshold with a named owner; wave order signed by domain owners — who could fail their own wave.
- **Build & Test (8–12 wks)** — domain waves behind published DQ gates — inventory and production first (numbers planners already believed), then purchasing/ASN, then transportation; shortage-alert rule specified (days-of-cover vs lane lead-time p90); daily reconciliation to MD04/COOIS/VA05/MB52; weekly root-cause loop with false alarms worked as defects. *Exit bar:* per-domain completeness ≥ gate; reconciliation passing daily; false alarms trending down; pilot planners using the alert.
- **Cutover & Go-Live (4 wks)** — views live for pilot planners with the at-risk list replacing the Monday spreadsheet; nobody mandated off the spreadsheet — rollback stayed free. *Exit bar:* planners answer "where is my product" from the platform in the live S&OP meeting.
- **Hypercare / Close (4 wks)** — exception workbench staffed; weekly root-cause reviews handed to domain owners; the safety-stock release rule signed with Planning and Finance — release only where forecast error AND lead-time error both improved. *Exit bar:* blockers/day under threshold two consecutive weeks; the release survives audit.

Influence and ownership. Mine: the definitions memo, the metrics tree, the DQ scorecard spec, the wave sequence, the release rule and the onboarding playbook. The client's SAP teams and our integration engineers built the feeds; planners owned the forecast — I owned its measurement (MAPE/bias per SKU family) and the release rule; domain owners held sign-off over their own gates. The MPN worklist gated longer than planned — escalated to the sponsor as a re-sequenced date with the coverage number attached, not a slip.

> **Designed the process; others own it now.** I designed the definitions, the DQ gates, the release rule and the onboarding playbook; domain owners now run the gates and the weekly root-cause reviews, and planners run the alert without me. **Trade-off put to leadership.** The recommendation to Planning and Finance outlined the competing metrics — working capital released vs service risk — and resolved it as a rule: release only where forecast error and lead-time error both improved.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY (CANON NUMBERS ONLY)

- **$** — $2M safety stock released (record, one-time working capital, under the both-errors-improved rule signed with Planning and Finance) + ≈$0.8M/yr *modeled* recurring (carry ≈$0.2M at 10% · expedites pre-empted ≈$0.3M · planner capacity ≈$0.3M; range $0.5–1.2M) — never added to S8's $1.5M.
- **#** — eight data domains into one view across six sites; shortage-alert product live in 3 months; adoption 8× (record).
- **%** — forecast accuracy 70% → 85% on scoped class-A SKUs (record); planner collaboration +50% (record, Apple F3); shipment data incomplete at the start (the 60% → 95% completeness figure belongs to S9 — do not quote it here).
- **Time** — the alert fires at days-of-cover ≤ lane lead-time p90 — a lead-time early instead of at line-down (record mechanism); views live in 3 months (the alert product; the six-site ingest is a separate 5-month program — never paste 3 months onto it).
- **Customer** — "which customer orders are at risk this quarter?" answered from the platform in the live S&OP meeting, not a spreadsheet (record exit bar).
- **Quality** — daily reconciliation to MD04/COOIS/VA05/MB52; false alarms classified weekly to root cause and burned down as defects (record).

L6 LEVEL EVIDENCE — what the interviewer pattern-matches against the Amazon L6 functional rubric; every line is this story's canon, no new numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	Eight data domains, six sites and no shared definition of supply. I wrote the definitions memo (grain SKU × location × date; supply = on-hand + production plan + released planned orders only) and the metrics tree, and chose the domain owners who would sign their own gates.
Scope & influence	The client's SAP teams and our integration engineers built the feeds; planners owned the forecast; Planning and Finance signed the release rule; domain owners held sign-off over their gates — none reporting to me.
Execution trade-off + mechanism others now own	Working-capital release vs service risk: release only where forecast error AND lead-time error both improved. Mechanisms others own now: the DQ scorecard, the 10-step onboarding playbook and the weekly root-cause reviews handed to domain owners.
Impact (long-term)	$2M of safety stock released (record); forecast accuracy 70% → 85% on class-A; planner collaboration +50%; the shortage alert fires a lead-time early instead of at line-down.
Process improvement (standard work institutionalized)	Domain waves behind published DQ gates; daily reconciliation to MD04/COOIS/VA05/MB52; false alarms classified weekly to root cause and burned down as defects.
Complexity & consensus	Nobody was mandated off the Monday spreadsheet — rollback stayed free until planners answered "where is my product" from the platform in the live S&OP meeting; the MPN worklist gated longer than planned and the gate held.
Root cause at scale	Unfirmed orders inflating supply was a definition defect, not a planner habit — fixed once in the supply definition and applied across all six sites.

THE FIVE FACETS NEW — data analysis · solution design · math & data logic · implementation · probe questions; each labeled so the interviewer can see all five are present

1 · Data analysis	Data: eight domains (supplier, material, BOM, inventory, production, transportation, sales-order, planning) across six sites; shipment data incomplete at the start (the 60% figure is S9's); MAPE and bias at the SKU-family grain on scoped class-A SKUs. Revealed: unfirmed MRP orders inflated supply; the lane's own lead time was unmeasured.
2 · Solution design	Options: count unfirmed orders or not · alert at brochure lead time or measured p90 · release buffer on accuracy alone or on both signals. Chosen: released planned orders only; alert at DoC ≤ lane p90; release only where both errors improved.
3 · Math & data logic	Math: DoC = on-hand ÷ daily demand = 1,200 ÷ 100 = 12 ≤ p90 14 → alert; SS = z·d·σ_L = 2.33 × 100 × 4 = 932 → 466 at σ_L 2; alert precision 71.2% / recall 98.6% at p90; both-errors rule false-release rate under noise 25% → 2.5% with a one-SE bar.
4 · Implementation	Implementation: definitions memo → data-quality gates per domain → waves sequenced by planner trust → daily reconciliation to SAP source → alert live in 3 months → release rule signed → false alarms classified weekly.
5 · Probe questions	Probe questions: MAPE vs bias · what "accuracy" means · why p90 for the alert and p99 for the promise · false alarms · whether "both improved" is signal or noise — see Trap Drills.

PROBING — CHALLENGE Q&A TUNED TO THIS INTERVIEWER

> **Analytics — How was 70 → 85% measured, and on what?**
>
> Accuracy = 1 − MAPE on the scoped class-A SKUs, with bias published alongside it from month two, at the SKU-family grain the planners decide on. The planners owned the forecast; I owned the measurement and the input integrity — I have not owned a demand forecast end-to-end and won't claim it.

> **Analytics — Why exclude unfirmed MRP planned orders from supply? That understates it.**
>
> Deliberately. Unfirmed orders breathe every MRP run; counting them amplifies noise and inflates supply, which is exactly how the line-down surprises happened. Released planned orders only — accepted by planners before the first screen was built.

Analytics — The $2M — how do I know it is not a prettier average?

Because of the release rule: buffer came out only on SKU families where forecast error and lead-time error had both demonstrably improved, signed by Planning and Finance. That is why the release survived audit. It is one-time working capital; the recurring value around it is my model and labeled.

Analytics — Your expedite row is the softest. Defend it.

Agreed — about sixty expedites a year pre-empted at a $5K premium, both illustrative. The record is the mechanism: the alert fires at days-of-cover ≤ lane p90. To firm it I would pull the expedited-freight ledger for the six sites twelve months before and after the alert went live and count the premium directly.

Analytics — Why p90 for the alert threshold and p99 for the promise (S8)?

Different decisions. The alert is a re-plan trigger — p90 gives the planner a window before the tail bites. The promise is a commitment — it sits at the tail you can defend. Same measured distribution, two policies read off it.

Analytics — Define your two error metrics: MAPE versus bias. Which one steered?

MAPE is mean absolute percentage error — how wrong the forecast is on average, direction ignored; bias is the signed mean error — whether it runs systematically high or low. MAPE without bias hides a chronic over-forecast inside a decent average, and a chronic over-forecast is exactly how buffer quietly accumulates. So accuracy was reported as 1 − MAPE on the scoped class-A SKUs at the SKU-family grain, with bias published alongside from month two — and the release rule required forecast error and lead-time error both to improve, so neither metric could carry the decision alone.

Analytics — What are the precision and recall of an alert at the lane's p90?

On an illustrative lane — replenishment time normal with mean 10 and σ 3 days, so p90 = 13.8 — and days-of-cover states uniform across 0–120 days: of every 1,000 checks about 83 would run short without action; the p90 alert fires on about 115; 71.2% of alerts are real (precision) and 98.6% of shortages are caught (recall). Moving to p99 lifts recall to 99.9% and drops precision to 58.8%. Illustrative lane; the record is the rule, DoC ≤ lane p90.

Analytics — Two kinds of false alarm — how do you tell them apart?

Statistical and defect. A designed false positive is an alert on a lane that turned out fine — at p90 about 29% of alerts by construction; that is the price of the window. A defect false alarm is the data lying — a wrong on-hand, a missing receipt, an unfirmed order counted as supply. The record burns the second kind down weekly by root cause; I do not let the first kind masquerade as a data problem.

Analytics — Is "both errors improved" signal or noise?

Under no real improvement each metric is a coin flip, so both improve by chance 25% of the time — on 100 families, about 25 false releases. Requiring each to beat its own standard error cuts that to 2.5% (about 2.5 families); two standard errors, 0.05%. The record says "demonstrably improved"; how that was operationalized is a number I would confirm before I quote one. VERIFY-WITH-RAJESH

Analytics — Why does bias matter when MAPE is already 15%?

Because direction compounds. A +10% over-forecast on 100 units a day adds 70 units a week; in 13.3 weeks the excess alone equals the whole 932-unit buffer on the example lane. MAPE tells you how far off; bias tells you which way the stock is piling up.

Shadow / closing — What would you do differently?

Start the MPN-mapping worklist on day one — it is never "done" and it gated more than I planned. And define supply honestly before any screen, which held.

THE KEY MATH — THE NETTING WALK AT FINISHED-GOODS GRAIN, THE ALERT RULE AND THE TWO-SIGNAL RELEASE (ILLUSTRATIVE VALUES; RECORD PERCENTAGES)

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Accuracy before / after	`1 − 0.30 = 70% → 1 − 0.15 = 85%`	record	70% → 85%
2	Honest supply	`supply(t) = on-hand + in-transit ≤ t + production ≤ t + RELEASED planned orders`	record rule	unfirmed MRP orders excluded
3	Projected balance (FG SKU)	`PAB(3) = 400 − 500 = −100; PAB(7) = 1,000 − 1,200 = −200; PAB(10) = 1,800 − 1,600 = +200`	illustrative FG example — timing shortage, not volume	fix window = day 9 − day 7 = 2 days
4	Alert rule	`DoC = 1,200 / 100 = 12 days ≤ lane p90 14 → alert; p90 = 9 → no alert`	record design; values illustrative	a lead-time early, no false alarm on the fast lane
5	Two-signal release	`SS = z·d·σ_L = 2.33 × 100 × 4 = 932 → σ_L 2: 466; release 466 units — only if BOTH errors improved`	toolkit illustration; the rule is record	release survives audit
6	Recurring value	`$2M × 10% = $0.2M · 60 × $5K = $0.3M · 2.4 FTE × $120K = $0.3M`	modeled (benchmarks labeled)	≈$0.8M/yr; $2M one-time record

MRP math at finished-goods grain only — no BOM explosion in this packet. The six-site ingest (S7) is a separate program; never paste this story's "3 months" onto it.

Where this lands at Amazon. Placement rests on two error signals — forecast error and lead-time error — measured at the decision grain. The transferable disciplines: define supply before the screen, alert at the last moment a re-plan is cheaper than an expedite, and release buffer only when both error signals improve. Reliability (shortage seen a lead-time early), cost efficiency (expedites pre-empted), asset utilization ($2M of working capital released on evidence).

FULL DERIVATION — FOUR-TABLE MATH, SOLUTION FLOW, SENSITIVITY, SPOKEN STATEMENT, IF-CHALLENGED NEW

BUSINESS IMPACT MODEL — KPI TREE, NUMBERS, THE MATH

```
Customer orders at risk this quarter -> answered a lead-time early
+- Inventory $ (stock): $2M safety stock released (record)
|    +- forecast error 30% -> 15% (accuracy 70 -> 85%, record)
|    +- lead-time error (lane p90 measured, not brochure)
|    +- release rule: BOTH errors improved -> SS = z*sigma*sqrt(L) falls
+- Shortage response (flow): alert when DoC <= lane LT p90
|    +- fix window = LT p90 - DoC: days to re-plan instead of fly
+- Planner collaboration +50% (record, Apple F3) -> hours to root cause, not reconciliation
+- Data-integrity loop: daily recon -> defects burned down -> planner trust (+)
     -> adoption 8x -> more domains feed the peg -> errors fall further (+)
```

DRIVER	BASELINE	AFTER	$/YR	BASIS
Forecast accuracy, class-A SKUs	70%	85%	—	record
Safety stock released (one-time)	—	$2M out	—	record
Carry on released $2M	tied up	free	$0.2M	modeled ($2M × 10% WACC; benchmark 8–12%)
Expedites avoided via the alert	~150 events/yr	~60 pre-empted	$0.3M	modeled (60 × $5K; premium benchmark $3–8K)
Planner effort on reconciliation	12 × 40%	12 × 20%	$0.3M	modeled (2.4 FTE × $120K; −50% is record)

DRIVER	BASELINE	AFTER	$/YR	BASIS
Total modeled recurring	—	—	**≈$0.8M**	around the $2M one-time record; never added to S8's $1.5M

If challenged. *"The $2M — measured how?"* — "It's the record: the release Finance signed, applied only on SKU families where forecast error and lead-time error had both demonstrably improved. That rule is why the release survived audit — capital came out on evidence, not on a better-looking average." *"150 shortage events?"* — "Illustrative volume — six sites at roughly 25 escalations a year. The record is the mechanism: the alert fires at days-of-cover ≤ lane p90, which is the last moment a re-plan is cheaper than a flight."

THE MATH — STEP-BY-STEP DERIVATION

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Forecast accuracy	`accuracy = 1 − MAPE = 1 − 0.30 = 70%`	scoped class-A SKUs (record)	70%
2	What the error math looks like	`MAPE = (30/100 + 10/120 + 20/80 + 10/100)/4 = (0.30 + 0.083 + 0.25 + 0.10)/4 = 18.3%`	4 illustrative weeks: A = 100, 120, 80, 100; F = 130, 110, 100, 90; |e| = 30, 10, 20, 10	18.3% on this sample; bias = (430 − 400)/400 = +7.5%
3	The supply lie	`supply counted unfirmed MRP planned orders — they change every run`	record problem	plans built on sand
4	Shortage discovery	`at line-down: ~150 expedite events/yr`	benchmark-modeled count	~150 fire-drills/yr
5	Planner burn	`12 planners × 40% = 4.8 FTE-equivalent on reconciliation`	record share	4.8 FTE reconciling, not root-causing

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Honest supply	`supply(t) = on-hand + in-transit ≤ t + production ≤ t + RELEASED planned orders only`	unfirmed MRP planned orders excluded (record rule)	walked below on ROUTER-100
2	FG netting walk — setup	`FG SKU ROUTER-100 at DC-East: on-hand 400; in-transit 600 lands day 5; production 800 day 9; demand 500 d3 / 700 d7 / 400 d10`	illustrative (v105 §5.12)	projected balance below
3	Day 3	`PAB(3) = 400 − 500 = −100`	only on-hand has arrived by day 3	dated shortage of 100 on day 3
4	Day 7	`PAB(7) = (400 + 600) − (500 + 700) = 1,000 − 1,200 = −200`	day-9 production is too late for day-7 demand	shortage of 200; fix window = 9 − 7 = 2 days
5	Day 10	`PAB(10) = (400 + 600 + 800) − (500 + 700 + 400) = 1,800 − 1,600 = +200`	all supply lands by day 10	+200 — the shortage is timing, not volume
6	Shortage alert rule	`DoC = 1,200 / 100 = 12 days; 12 ≤ p90 14 → alert now`	FG SKU: on-hand 1,200 at 100/day; lane p90 = 14 days (illustrative)	alert a lead-time early, not at line-down
7	Counter-case	`p90 = 9 days: 12 > 9 → no alert`	same SKU, faster lane (illustrative)	3-day slack — no false alarm

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
8	Two-signal release rule	`SS = z × d × σ_L = 2.33 × 100 × 4 = 932; with σ_L 4 → 2: 2.33 × 100 × 2 = 466; release 932 − 466 = 466 units`	release only if forecast error AND lead-time accuracy both improved; d = 100/day, z = 2.33 at 99% (illustrative, toolkit form)	466 units off this SKU
9	Accuracy after	`error 30% → 15% (halved); accuracy = 1 − 0.15 = 85%`	gated waves; false alarms worked as defects (record)	85%

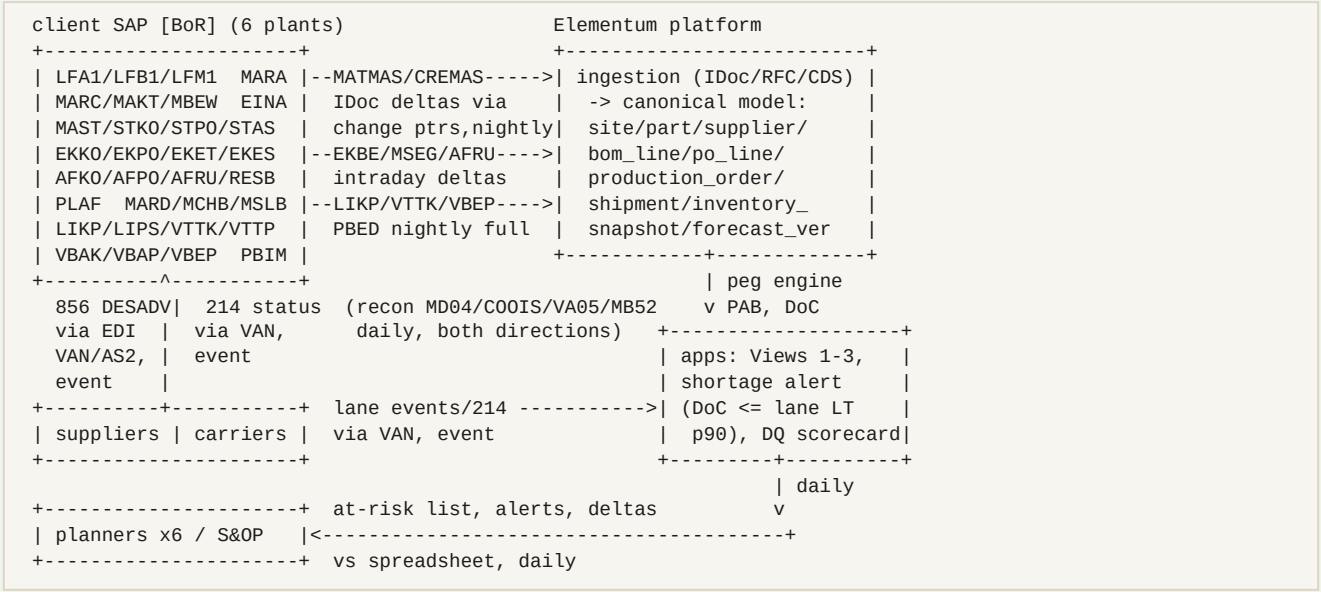

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Forecast accuracy, class-A SKUs	70%	85%	record
2	Shortage discovery	at line-down	a lead-time early (DoC ≤ p90 alert)	record design
3	Planner reconciliation share	12 × 40% of time	12 × 20% — halved	record (−50%)
4	Safety stock	sized on bad signals	$2M released one-time under the signed two-signal rule	record

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Carry on the release	`$2,000,000 × 10% = $200,000`	$2M release (record, one-time) × WACC (benchmark 8–12%)	≈$0.2M/yr
2	Expedites pre-empted	`150 × 40% = 60 caught early; 60 × $5,000 = $300,000`	events/yr modeled; premium benchmark $3–8K	≈$0.3M/yr
3	Planner capacity	`12 × 40% = 4.8 FTE; halved → 2.4 FTE; 2.4 × $120,000 = $288,000`	−50% is record; capacity redeployed, not headcount removed	≈$0.3M/yr
4	Total recurring	`0.2 + 0.3 + 0.3 = $0.8M`	modeled; never added to S8's $1.5M	≈$0.8M/yr
5	One-time	`$2M safety stock released, taken as stated`	record, under the signed two-signal rule	$2M

SOLUTION FLOW — THE SYSTEM & DATA MAP

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Cost of capital (benchmark)	8% → $0.16M	10% → $0.20M	12% → $0.24M
Expedites avoided (illustrative)	45	60	75
Expedite premium (benchmark)	$3K → $0.14M	$5K → $0.30M	$8K → $0.60M
Loaded planner cost (benchmark)	$100K → $0.24M	$120K → $0.29M	$140K → $0.34M
Total modeled $/yr	≈$0.5M	≈$0.8M	≈$1.2M

ALERT-THRESHOLD DESIGN — PRECISION, RECALL AND THE COST OF A FALSE ALARM (EXTRA TABLE)

The record is the rule — alert when days-of-cover ≤ the lane's measured p90 lead time. Everything below is my after-the-fact design arithmetic on an illustrative lane, so the threshold can be defended in numbers. VERIFY-WITH-RAJESH how p90 was originally chosen.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	The lane	`replenishment time L ~ Normal(μ = 10, σ = 3); p90 = 10 + 1.2816 × 3 = 13.84 ≈ 14 d`	illustrative lane (matches the p90 = 14 example)	θ = 13.84 d
2	Shortage if no action	`P(L > DoC) = 1 − Φ((DoC − 10)/3); DoC uniform on 0–120 d → ≈ 10/120 = 8.3% of checks`	states illustrative; ∫P(L > x)dx = E[L] = 10	83.3 per 1,000 checks
3	Alert rule (record)	`alert iff DoC ≤ θ: alerts per 1,000 = 1,000 × 13.84 ÷ 120 = 115`	record design; values illustrative	115 alerts / 1,000
4	Precision (p90)	`TP ÷ alerts = 82.15 ÷ 115.37 = 71.2%`	numerical integral of P(L > DoC) over DoC ≤ θ	71.2%
5	Recall (p90)	`TP ÷ shortages = 82.15 ÷ 83.34 = 98.6%`	same integral	98.6%
6	Same lane at p99	`θ = 16.98 d; alerts 141; precision 58.8%; recall 99.9%`	same method	more alerts, little recall gained
7	Cost of a false alarm vs a miss	`planner hour ≈ $120K ÷ 2,000 h = $60; a missed shortage ≈ $5,000 (master expedite premium)`	both illustrative (master)	$60 vs $5,000
8	Expected cost per 1,000 checks	`p75 $24,656; p90 115.372 × $60 + 1.1836 × $5,000 = $12,840; p95 $10,079; p99 $8,913`	alerts × c_fp + misses × c_miss	p90 $12,840 vs p99 $8,913
9	Cost-optimal threshold	`alert iff P(L > DoC) ≥ c_fp ÷ c_miss = 60 ÷ 5,000 = 1.2% → quantile 98.8% → θ = 16.8 d`	critical-ratio logic	θ* = 16.8 d if c_miss were $5,000
10	What p90 implies	`p90 ⇔ c_miss ÷ c_fp = 0.90 ÷ 0.10 = 9 → c_miss = 9 × $60 = $540; p99 ⇔ $5,940`	after-the-fact derivation — not how p90 was chosen	p90 prices a miss at $540
11	Minimum shipments to bound the p90	`n = 31: t(24)…t(31); n = 30 → t(24)…open`	exact order-statistic interval (95%)	n ≥ 31 per lane; else cohort p90

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

"The measured number is two million dollars of safety stock released, and that is record, signed with planning and Finance under the both-errors-improved rule. Around it I model roughly eight hundred thousand a year of recurring value: about two hundred thousand in carry cost on the capital that came out, about three hundred thousand in expedite premium the shortage alert pre-empts because it fires a lead-time early instead of at line-down, and about three hundred thousand of planner capacity from the fifty percent effort cut. The two million and the fifty percent are measured; the three recurring pieces are my model on benchmark rates, and I keep them separate from the one-and-a-half million in the lane program."

If challenged — the full answers.

The expedite figure is the softest

It rests on about sixty expedites a year pre-empted at a five thousand dollar premium, both illustrative; to firm it I would pull the expedited-freight ledger for the six sites for the twelve months before and after the alert went live and count the premium directly.

Planner capacity is not cash

Agreed, it is two point four FTE of time redeployed, not headcount removed; the fifty percent is measured, the forty percent share of the week is my assumption, and a two-week time study on the S&OP prep cycle would replace it.

Why not claim the whole two million every year

Because a release is a one-time working-capital event; the recurring value is the carry at eight to twelve percent, and I would rather say two hundred thousand a year honestly than two million a year wrongly.

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE WITH S6

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Tell me about a time you had to dig into the data to find the real problem.	Dive Deep	The supply definition — unfirmed orders inflating supply — found by profiling eight domains; MAPE and bias at the grain planners decide on.	Skip the SAP table names unless asked; systems are enablers.
Tell me about a time you released inventory / improved working capital.	Frugality / Deliver Results	$2M under the two-signal rule — record, one-time; the recurring ≈$0.8M labeled modeled.	Never add the $2M to S8's $1.5M; never claim $2M per year.
Tell me about a time you were right when the business disagreed.	Are Right, A Lot	Refusing unfirmed MRP orders as supply because it looked better; refusing a blanket safety-stock release — agreed as a rule instead.	Do not make Planning the villain; the rule did the refusing.
How do you get planners to trust a new signal?	Earn Trust	Waves sequenced by trust (inventory and production first); false alarms worked as defects; nobody mandated off the spreadsheet; domain owners could fail their own wave.	Do not claim adoption dollars; adoption 8× is the record.
How would you design a shortage / at-risk-order signal for the network?	Functional — Plan process design	Grain, honest supply, days-of-cover vs measured lane p90, DQ gate per feed, two-signal release — the §3.99 opening: book of record and metric first.	No BOM explosion; finished-goods grain only.
What's the softest number in your model?	Highest Standards / Earn Trust	The expedite row (60 × $5K); how I would firm it from the expedited-freight ledger.	Never present planner capacity as cash — it is time redeployed.

BEHAVIORAL PACK NEW — FOUR QUESTIONS THIS STORY ANSWERS, FOUR SEPARATE 90-SECOND ANSWERS (EACH FROM A DIFFERENT MOMENT OF THE STORY)

Q1 **Tell me about a time you dug into the data to find the real problem.** DIVE DEEP

Open (first two sentences): Leadership asked which customer orders were at risk, and the first thing I did was refuse to answer until we agreed what “supply” meant.

STAR (≈90 s): Situation: a six-site manufacturer found out about shortages when the line stopped; shipment data was incomplete across about eight domains. Task: nobody owned the seam, so I took definitions and data integrity. Action: profiled every domain for completeness, latency and joinability, and defined supply honestly — on-hand plus production plan plus released planned orders only; unfirmed MRP orders change every run and had been inflating supply. Result: the alert product live in three months; forecast accuracy 70 to 85% on the scoped class-A SKUs; planners accepted the definition before the first screen existed.

Land this number: 60% shipment-data completeness → daily reconciliation to SAP; 70% → 85% accuracy. · **Pivot to NACF:** NACF inbound “available” and “on-hand” need one signed definition before any placement model reads them. · **Do NOT say:** Do not say I owned the forecast; planners did — I owned the measurement and the input integrity.

Q2 **Tell me about a time you needed buy-in from Finance and Planning on a risky change.** EARN TRUST

Open (first two sentences): Releasing $2M of safety stock is a risk Finance and Planning both carry, so the rule was theirs before it was mine.

STAR (≈90 s): Situation: buffer had grown on noisy forecasts and unmeasured lead times. Task: take capital out without a stockout. Action: I proposed a two-signal rule — release only where forecast error and lead-time error had both demonstrably improved — and got Planning and Finance to sign it before the first release. Result: $2M released and it survived audit because the exception was in the rule; ≈$0.8M a year modeled around it; never added to the other program’s $1.5M.

Land this number: $2M released (record, one-time); both-errors rule. · **Pivot to NACF:** A WOC reduction at Amazon needs the same pre-signed exception: cut only where both signals improved. · **Do NOT say:** Do not add $2M and $1.5M, and do not call the $0.8M recurring a result — it is modeled.

Q3 **Tell me about a time you delivered a result on a hard deadline.** DELIVER RESULTS

Open (first two sentences): Three months from kickoff, a planner could see a shortage a lead time before the line stopped.

STAR (≈90 s): Situation: the plan responded with expedites, not re-plans. Task: ship a shortage alert fast without shipping wrong data. Action: sequenced the domains in waves by planner trust, each behind a published data-quality gate, with daily reconciliation to SAP and false alarms worked as defects. Result: alert live in three months, planner collaboration up 50%, forecast accuracy 70 to 85%. The six-site ingest is a separate five-month program — I never paste the three months onto it.

Land this number: Alert live in 3 months; planner collaboration +50% (Apple F3); 70% → 85%. · **Pivot to NACF:** Same sequencing for NACF: trust-ordered waves, a quality gate per source. · **Do NOT say:** Do not stretch “3 months” to the full ingest.

Q4 **Tell me about a time you owned something nobody owned.** OWNERSHIP

Open (first two sentences): Eight domains, six sites, and the question “which customer orders are at risk?” had no data path and no owner.

STAR (≈90 s): Situation: S&OP ran off private spreadsheets and the seam between systems and planners belonged to nobody. Task: own it. Action: I wrote the definitions memo, the data-quality scorecard spec, the wave sequence and the release rule, and stayed through hypercare. The thing I would do differently: start the MPN-mapping worklist on day one — it is never done and it gated more than I planned. Result: the question was answered in the live S&OP meeting from the platform, not a spreadsheet.

Land this number: Eight domains into one view; alert in 3 months. · **Pivot to NACF:** Placement analytics lives on that seam too: forecast error and lead-time error from different systems. · **Do NOT say:** Do not claim the client’s SAP teams’ feeds were mine.

SAME STORY, THREE ANGLES NEW — THREE DIFFERENT OPENERS, HEADLINE METRICS AND LPS FROM THE SAME FACTS

(I) DATA / ANALYTICAL

LP: Dive Deep

Open: “I would not build a screen until we agreed what supply was.”

Headline metric: unfirmed MRP orders excluded; accuracy 70% → 85%

- MAPE with bias published from month two.
- Alert at DoC ≤ lane p90: precision 71% / recall 99% (illustrative lane).
- DoC 12 ≤ p90 14 → alert; p90 9 → no alert.
- False alarms: designed vs defect.

(II) CONFLICT / INFLUENCE / BACKBONE

LP: Earn Trust; Have Backbone

Open: “Planners wanted the unfirmed orders in supply because it looked better; I refused them.”

Headline metric: released planned orders only; $2M under a signed rule

- Accepted by planners before the first screen.
- Release only if both errors improved.
- Finance and Planning signed.
- A coin-flip rule would false-release 25% of families — so “demonstrably.”

(III) FAILURE — LEARNING — WHAT I WOULD DO DIFFERENTLY

LP: Ownership; Learn and Be Curious

Open: “The MPN-mapping worklist is never done — I should have started it on day one.”

Headline metric: MPN mapping gated more than planned (record lesson)

- The lesson is in the record.
- Define supply honestly before any screen — that held.
- I did not own the forecast and say so.
- VERIFY-WITH-RAJESH the size of the delay MPN mapping caused.

TRAP DRILLS NEW — THE THREE NASTIEST FOLLOW-UPS A STATISTICALLY RIGOROUS INTERVIEWER THROWS

T1 **“Your alert fires at the lane’s p90 — what are its precision and recall, and why not p99?”**

The numbers: Illustrative lane N(10, 3): θ = 13.84; precision 71.2%, recall 98.6%; p99 precision 58.8%, recall 99.9%; p90 ⇔ miss costs 9× a false alarm.

Say exactly: “On an illustrative lane the p90 alert catches about 99 percent of shortages with about 71 percent precision; p99 buys about one more point of recall for twelve points of precision. A p90 threshold prices a miss at nine false alarms — at a sixty-dollar alert and a five-thousand-dollar miss the cost-optimal threshold would sit higher, which is why I would show planners the curve and let their own cost of an alert set the dial.”

T2 **“Both-errors-improved — what is the false-release rate if neither metric really improved?”**

The numbers: Coin-flip: 25% of families; each beat by one SE: 2.52%; two SE: 0.052%; on 100 families: 25 / 2.5 / 0.05.

Say exactly: “If nothing improved, a bare both-up rule releases a quarter of the families by luck; requiring each metric to beat its own standard error takes it to about two and a half percent — which is why the rule said demonstrably improved, not merely improved.”

T3 **“Why does bias matter if your accuracy is 85%?”**

The numbers: SS = 2.33 × 100 × 4 = 932; +10% bias × 100/day × 7 = 70/week; 932 ÷ 70 = 13.3 weeks.

Say exactly: “Accuracy is a magnitude; bias is a direction. A ten-percent over-forecast adds seventy units a week on a hundred-a-day SKU — in under fourteen weeks the excess alone equals a nine-hundred-unit buffer, which is how buffer quietly accumulates behind a decent MAPE.”

S8 — Elementum — replacing brochure lead times with measured lane distributions: promise at p99 on 200 lanes, 99% lead-time accuracy, 580K units freed / ~$1.5M of inventory carrying cost released with zero stockouts ELEVATED

LPs this story can serve here: Dive Deep (primary — measured the distribution, not the average) · Are Right, A Lot (backup — measured vs brochure; p99 on the asymmetry) · Frugality (the release) · Insist on the Highest Standards (the 99% bar before any cut) · Earn Trust (Finance signed each lane; the exception written into the rule)
Process family: Plan / Source / Deliver seam — inbound lead-time policy, safety-stock sizing, promise policy; parameter governance with a drift flag

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH NEW

- **Dive Deep** — I measured each lane's own distribution — mean, spread, tail — instead of accepting a carrier brochure or a network average.
- **Customer Obsession** — The customer was the production line: I put the cost of a line-down next to the carrying cost per lane and let planning choose p99 with the asymmetry in front of them.
- **Earn Trust** — Finance signed each lane; the release rule carried its own exception — fat tails kept their buffer — before anyone asked.
- **Ownership** — I designed the promise policy and release rule as a signed planning act that planning re-applies on its own refresh.

Honesty label. I owned the requirement (measured lanes, not brochures), the p99 promise policy and the release rule; the data team built the distributions; planners sized the buffers; Finance signed the release. Lane-cohort counts and week markers are not in the record. The safety-stock formula is the MIT inventory-theory toolkit as I explain it now — an illustration, not a program artifact. Depends on the six-site canonical model (S7 — pointer only).

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. The same six-site manufacturer planned inventory on carrier-brochure lead times — every buffer sized on a variability nobody had measured: too much on reliable lanes, too little on fat-tailed ones. The logistics manager asked for a "lead-time variability report." **Task.** I reframed it as a parameter and policy problem — nobody owned the seam between transportation reality and planning parameters, and I took it — scoped at 200 lanes by site, lane and mode. **Action.** I wrote the requirement to the data team: mean, spread and tail per lane from actual production cycle plus inbound transit; defined the promise at p99 cumulatively — the smallest day d with $P(L \le d) \ge 0.99$, not average-plus-padding — and showed each lane's asymmetry, line-down cost against carrying cost, and let planning choose the percentile; they chose p99. The release rule was written as a signed planning act with the exception inside it: fat-tail lanes keep their buffer until the source process moves; Finance agreed the rule in the same room, before any cut. I would not endorse a release until lead-time accuracy hit 99% on the 200-lane set; the stockout-and-expedite watch was armed first; every parameter got a drift flag and a refresh cadence so the promise never decays into a new brochure. **Result.** Primary metric: lead-time accuracy on 200 lanes — brochure values → 99% at the p99 promise. 580K units, about $1.5M of safety stock, released without a stockout — record, one-time working capital — with ≈$0.6M a year modeled around it. A different program from the $2M forecast release; never added.

20-SECOND VERSION NEW

Two hundred lanes planned on carrier brochures; I replaced them with measured per-lane distributions, set the promise at p99, gated any cut on 99% lead-time accuracy and released 580K units, about $1.5M, with zero stockouts.

NACF BRIDGE — ONE SENTENCE

Inbound lead-time variability is half of every WOC target and every placement promise at NACF — I would measure each vendor lane's own distribution and promise at the tail I can defend before releasing any weeks of cover.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — The six-site manufacturer's logistics manager asked for a "lead-time variability report." The real problem: inventory planning ran on carrier-brochure lead times — every buffer sized on a variability nobody had measured; too much buffer on reliable lanes, too little on fat-tailed ones; the promise to the plan was folklore.

The risk cut both ways: keep planning on brochures and you hold too much on reliable lanes and stock out on fat-tailed ones; cut buffer without evidence and the stockout is yours. And an unmaintained promise decays into a new brochure — which is why every parameter needed a drift flag.

T — Nobody owned the seam between transportation reality and planning parameters; I took it. Goal: measured lanes replace catalog values; a promise at a defensible tail; buffer released only on evidence, with service held — scoped at 200 lanes by site, lane and mode.

Baselines on the table: lead-time parameters = carrier-brochure values, variability unmeasured · buffer capital sized on catalog values · no lead-time-accuracy measurement · target 99% lead-time accuracy on the 200-lane set before any release.

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery** — reframed the report request as a parameter problem; scoped 200 lanes by site/lane/mode; wrote the success criteria — measured lanes replace catalog values; buffer released only on evidence; fat tails keep buffer; showed one right-skewed lane where the average hid the tail. *Exit bar:* planning and logistics agree the problem is the parameter, not the report.
- **Plan & Design** — requirement to the data team (mean, spread, tail per lane; production cycle + inbound transit vs actual); the p99 promise policy (cumulative, not μ + 2.33σ); the release rule as a signed planning act with the fat-tail exception inside it; the stockout-and-expedite watch; drift flag and refresh cadence. On p95 vs p99, showed the asymmetry per lane and left the choice to planning. *Exit bar:* policy signed by planning; Finance agrees the release rule in the room; data team accepts the spec.
- **Build & Test** — data team built the lane distributions and tracked lead-time accuracy per lane; manual reconciliation stayed alive. *Exit bar:* lead-time accuracy 99% on the 200-lane set — the bar I would not endorse a cut below.
- **Cutover & Go-Live** — planners executed the buffer release lane by lane under the signed rule; fat-tail lanes excluded until their source process moved; watch armed first. *Exit bar:* 580K units / ~$1.5M released; no stockout in the watch window.
- **Hypercare / Close** — read the watch; set drift flags per lane; handed the refresh cadence and the release rule to planning as an act they could re-apply. *Exit bar:* watch clean; the promise stays measured.

Influence and ownership. I owned the requirement, the promise policy and the release rule; the data team built the distributions and tracked accuracy; planners sized the buffers and executed; Finance signed each lane. When Finance pushed for a broader release, the rule they had signed did the refusing — fat-tail lanes keep buffer until the source process moves. The percentile fight never happened: I showed each lane's line-down cost against carrying cost and planning chose p99 — their choice surviving an audit is worth more than my choice winning a meeting.

Designed the process; others own it now. I designed the promise policy and the release rule as a signed planning act; planning now re-applies it on its own refresh cadence with a drift flag per lane. **Trade-off put to leadership.** The recommendation to Finance and Planning outlined the competing metrics — ~$1.5M of working capital out vs stockout

> exposure at the tail — and set the bar: p99, 99% lead-time accuracy, fat-tail lanes excluded until their source process moved.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY (CANON NUMBERS ONLY)

- **$** — 580K units freed / ~$1.5M of inventory carrying cost released without a stockout (record — Apple F4 wording, never annualized; one-time working capital); ≈$0.6M/yr *modeled* recurring around it (carry ≈$0.3M at a benchmark 20% all-in rate + expedites avoided ≈$0.3M; range $0.3–1.4M) — a different program from S6's $2M; never added.
- **#** — 200 lanes measured by site, lane and mode; 580K units released (record); ≈$2.59/unit derived — low-value components.
- **%** — lead-time accuracy 99% on the 200-lane set at the p99 promise — the bar below which I would not endorse a cut (record).
- **Time** — release only after the 99% bar; watch window clean; refresh cadence and drift flag per lane handed to planning (record).
- **Customer** — service held — zero stockouts on released lanes through the watch window (record).
- **Quality** — release only under the signed rule; fat-tail lanes kept buffer until the source process moved; the promise stays measured, never a new brochure (record).

L6 LEVEL EVIDENCE — what the interviewer pattern-matches against the Amazon L6 functional rubric; every line is this story's canon, no new numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	A report request with no agreed parameter behind it. I reframed it as a parameter problem and wrote the success criteria myself: measured lanes replace catalog values; buffer released only on evidence; fat tails keep buffer.
Scope & influence	200 lanes by site, lane and mode; the data team built the distributions; planners sized and executed; Finance signed each lane — a planning act I designed and others executed.
Execution trade-off + mechanism others now own	Working capital out vs stockout risk: promise at p99 (cumulative), a 99% lead-time-accuracy bar below which I would not endorse a cut, fat-tail lanes excluded until their source process moved. Mechanism others own now: the release rule as a signed act, the refresh cadence and a drift flag per lane handed to planning.
Impact (long-term)	580K units freed / ~$1.5M of inventory carrying cost released without a stockout (record — Apple F4 wording, never annualized; one-time working capital); the promise stays measured, never a new brochure.
Process improvement (standard work institutionalized)	Lead-time accuracy tracked per lane; drift flags; the release rule written so planning can re-apply it without me.
Complexity & consensus	Finance pushed for a broader release — the rule they had signed did the refusing; the fat-tail exception was inside the rule, so it fired as policy, not as a judgment call.
Root cause at scale	Brochure lead times were the parameter error behind every excess buffer — fixing the parameter fixed all 200 lanes at once rather than one planner's buffer at a time.

THE FIVE FACETS NEW — data analysis · solution design · math & data logic · implementation · probe questions; each labeled so the interviewer can see all five are present

1 · Data analysis	Data: shipment durations per lane (ship-to-receipt) for 200 lanes by site, lane and mode; the brochure value beside each. Revealed: lanes with measured σ far below the brochure (release) and lanes above it (keep).
2 · Solution design	Options: brochure · average · p95 · p99 per lane · network-wide percentile. Chosen: promise at the lane's own p99, cut only behind a 99% accuracy gate, fat tails kept.
3 · Math & data logic	Math: SS = z·d·σ_L = 2.33 × 500 × 5 = 5,825 vs 2.33 × 500 × 1.2 = 1,398; release 4,427; p99 = min{d : P(L ≤ d) ≥ 0.99}; $1.5M ÷ 580K = $2.59; upper-bound σ at n = 50 → 1,675.

4 · Implementation	Implementation: reframe the request → scope 200 lanes → data team builds distributions → planning chooses p99 on the asymmetry → accuracy gate → lane-by-lane release with Finance signature → watch + drift flag.
5 · Probe questions	Probe questions: p99 vs p95 · skew and the normal shortcut · what “99% accuracy” means · whether the release is selection-biased · whether the $1.5M is measured — see Trap Drills.

PROBING — CHALLENGE Q&A TUNED TO THIS INTERVIEWER

Analytics — Why p99 and not p95? That is a lot of buffer.

Per lane, the cost of a line-down on a fat-tailed lane dwarfed the carrying cost of the extra day. I showed the asymmetry lane by lane and let planning choose — they chose p99. On reliable lanes the measured σ was so far below the brochure that p99 still released buffer; on fat-tailed lanes the buffer stayed.

Analytics — How did you compute p99 on skewed lanes?

Cumulatively from the empirical distribution — the smallest d with $P(L \le d) \ge 0.99$ — not $\mu + 2.33\sigma$. On one right-skewed lane the normal shortcut understated the true p99 by about 3.4 days; that lane is why the definition is cumulative.

Analytics — Is the $1.5M measured?

The release is record: 580K units out, zero stockouts in the watch window, Finance signed each lane. The ≈$2.59/unit is the derived average. What is modeled is the recurring value around it — carry at 20% all-in (capital-only would be ≈$150K at 10%) and avoided expedites — each input labeled.

Analytics — The expedite number assumes what?

Ten thousand shipments a year on the 200 lanes and one late arrival in ten forcing an expedite before p99 — illustrative. I would pull the expedite ledger by lane for the year before and after and compare directly.

Analytics — What is lead-time accuracy, exactly?

1 − |actual − promised| / promised, tracked per lane against the p99 promise; the bar was 99% on the whole 200-lane set. Below it, no release — written into the act before anyone asked.

Analytics — At what grain did you measure lead time, and over what window?

At the lane grain, from actual ship-to-receipt durations — one empirical distribution per lane, never a network average. The record carries the per-lane distributions, the refresh cadence and the drift flag (p99 recomputed on refresh; the buffer decision re-opens if accuracy falls); it does not carry a quoted window length, and I will not invent one — what mattered design-wise was a window long enough to hold seasonality and recent enough that a dead lane's history could not vote, with the drift flag as the safety net either way.

Analytics — Why p99? What cost ratio does that imply?

A p99 promise is the critical ratio 0.99 = Cu ÷ (Cu + Co), i.e. a late day costs 99 times an extra day of cover. On the example lane an extra day of cover is 500 × $2.59 × 20% ÷ 365 = $0.71, so p99 is justified if a day of shortage costs more than about $70; p95 if more than $13. A line-down clears both bars by orders of magnitude — which is the asymmetry I showed planning lane by lane.

Analytics — Lanes released are lanes with a small measured σ. Isn’t that selection bias?

Yes — the winner’s curse. A lane picked because its measured σ looks small is partly a lucky draw. The standard error on σ is about $\sigma \div \sqrt{2(n-1)}$: 10.1% at n = 50, 3.5% at n = 400. On the reliable lane (σ 1.2, brochure 5), sizing on the 95% upper bound at n = 50 gives σ = 1.44 and a buffer of 1,675 instead of 1,398 — 277 units more, a release of 4,150 instead of 4,427. That is the arithmetic; VERIFY-WITH-RAJESH what the program did on thin lanes.

Analytics — Define “99% lead-time accuracy” so I can test it.

The master’s definition is LTacc = 1 − |actual − promised| ÷ promised with a 99% bar on the 200-lane set. Read per shipment against a p99 promise it cannot be 99%: on the example lane the mean shipment is 21 days against a 34-day promise, |21 − 34| ÷ 34 = 38.2%, a score of 61.8%. The readings consistent with 99% are coverage — 99 of 100 shipments arrive within the promise — or the re-measured lane p99 within 1% of the promised p99, a tolerance of 0.34 day on a 34-day lane. On the ratio form 1% is 0.05 day on a 5-day lane and 0.3 day on a 30-day lane. I would say which reading before quoting a tolerance. VERIFY-WITH-RAJESH

Shadow / closing — How does the promise stay honest after you leave?

Drift flag per lane with a refresh cadence: p99 is recomputed on refresh, and the buffer decision re-opens if accuracy falls. The stockout-and-expedite watch became a standing report owned by planning.

THE KEY MATH — ONE RELIABLE LANE, ONE FAT-TAIL LANE, AND THE RECURRING VALUE (ILLUSTRATIVE UNITS; RECORD PERCENTAGES AND THE RECORD RELEASE PAIR)

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Brochure-sized buffer	`SS = z·d·σ_L = 2.33 × 500 × 5 = 5,825 units`	illustrative; toolkit form	5,825 units of folklore
2	p99 defined cumulatively	`p99 = min{d : P(L ≤ d) ≥ 0.99}`	record definition	normal shortcut understates a skewed lane by 3.4 days
3	Reliable lane re-sized	`2.33 × 500 × 1.2 = 1,398; release = 5,825 − 1,398 = 4,427`	measured σ = 1.2 vs brochure 5 (illustrative)	4,427 units off this lane
4	Fat-tail lane	`2.33 × 500 × 6.5 = 7,573 — buffer KEPT`	measured σ = 6.5 > brochure 5 (illustrative)	kept until the source process moves
5	Accuracy gate	`LTacc = 1 − |actual − promised| / promised; bar 99% on 200 lanes`	record	99% held before any cut
6	The release	`$1,500,000 / 580,000 = $2.59/unit`	record pair; average derived	580K units / ~$1.5M, 0 stockouts
7	Recurring value	`$1.5M × 20% = $0.3M; 900 fewer late × 10% × $3K ≈ $0.27M`	modeled (benchmarks labeled)	≈$0.6M/yr; never added to S6's $2M

Depends on the six-site canonical model (S7) — six definitions cannot produce one σ. S7 is a pointer only in this packet; say "six sites," never "six NA sites."

Where this lands at Amazon. Inbound lead-time variability is half of every buffer and every promise in a placement model. Transferable: measure the lane's own distribution, promise at the tail you can defend, release capital only on evidence with the exception written into the rule, and give every parameter a drift flag. Reliability (zero stockouts), cost efficiency (expedites avoided), asset utilization (~$1.5M of working capital out).

FULL DERIVATION — FOUR-TABLE MATH, SOLUTION FLOW, SENSITIVITY, SPOKEN STATEMENT, IF-CHALLENGED NEW

BUSINESS IMPACT MODEL — KPI TREE, NUMBERS, THE MATH

```
Service held at lower inventory: 580K units / ~$1.5M released (record)
+- Safety stock (stock) = z * d * sigma_L per lane
|    +- sigma_L: brochure folklore -> measured per lane (200 lanes)
|    +- release rule: 99% LT-accuracy bar + fat-tail lanes keep buffer; Finance
|         signed each lane (S6's two-signal rule is that program's own control)
|    +- fat-tail lanes: sigma_L worse than brochure -> buffer KEPT
+- Promise integrity (flow): p99 per lane, LT accuracy 99% (record)
|    +- cost asymmetry: line-down >> one day of holding -> p99 not p95
+- Drift loop: refresh cadence -> p99 recomputed -> drift flag ->
     buffer decision re-opened -> promise stays measured, never a new brochure
```

DRIVER	BASELINE	AFTER	$/YR	BASIS
Lead-time accuracy, 200 lanes	brochure	99% at p99	—	record
Safety stock released (one-time)	brochure-sized	measured-sized	—	record: 580K units / ~$1.5M
Stockouts on released lanes	—	0 in watch	—	record
Carry on released $1.5M	held	free	$0.3M	modeled ($1.5M × 20% all-in carry; benchmark 15–25%)
Expedites on late arrivals	~1,000 late × 10%	~100 × 10%	$0.3M	modeled (90 × $3K)
Total modeled recurring	—	—	**≈$0.6M**	around the ~$1.5M record; never added to S6's $2M

If challenged. *"Is the $1.5M measured?"* — "The release is record: 580K units out, no stockout in the watch window, Finance signed each lane. The ~$2.59/unit is the derived average on low-value components. What's modeled is the recurring value around it — carry and expedites — and each input is labeled." *"Why did you own the percentile choice?"* — "I didn't — I owned the frame. I showed each lane's asymmetry, line-down cost against carrying cost, and planning chose p99. Their choice surviving an audit is worth more than my choice winning a meeting."

THE MATH — STEP-BY-STEP DERIVATION

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Lead-time parameters	`carrier-brochure values; variability unmeasured on 200 lanes`	record	folklore, not data
2	One lane sized on folklore	`SS = z × d × σ_L = 2.33 × 500 × 5 = 5,825 units`	d = 500 units/day; brochure σ = 5 days; z = 2.33 at 99% (illustrative, toolkit form)	5,825 units of buffer
3	Tail blindness	`normal shortcut μ + 2.33σ understates a right-skewed lane's true p99 by 3.4 days`	illustrative from the record	the promise misses the tail
4	Late arrivals	`200 lanes × ~50 shipments = 10,000/yr; × 10% = 1,000 late/yr`	volumes illustrative	~1,000 late/yr

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Measure per lane	`μ, σ, p50, p90, p99 from shipment history, 200 lanes`	production cycle + inbound transit vs actual (record)	measured distributions
2	p99 defined cumulatively	`p99 = min{d : P(L ≤ d) ≥ 0.99}`	not μ + 2.33σ unless the lane is normal (record definition)	the tail promise
3	Accuracy gate	`LTacc = 1 − |actual − promised| / promised; bar = 99% on the 200-lane set`	before endorsing any cut (record)	99% held
4	Reliable lane re-sized	`SS = 2.33 × 500 × 1.2 = 1,398; release = 5,825 − 1,398 = 4,427 units`	measured σ = 1.2 days vs brochure 5 (illustrative)	4,427 units off this lane

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
5	Fat-tail lane	`SS = 2.33 × 500 × 6.5 = 7,573 units — buffer KEPT`	measured σ = 6.5 > brochure 5 (illustrative)	kept until the source process moves
6	Drift flag	`p99 recomputed on refresh; buffer decision re-opened if accuracy falls`	record	the promise stays measured, never a new brochure

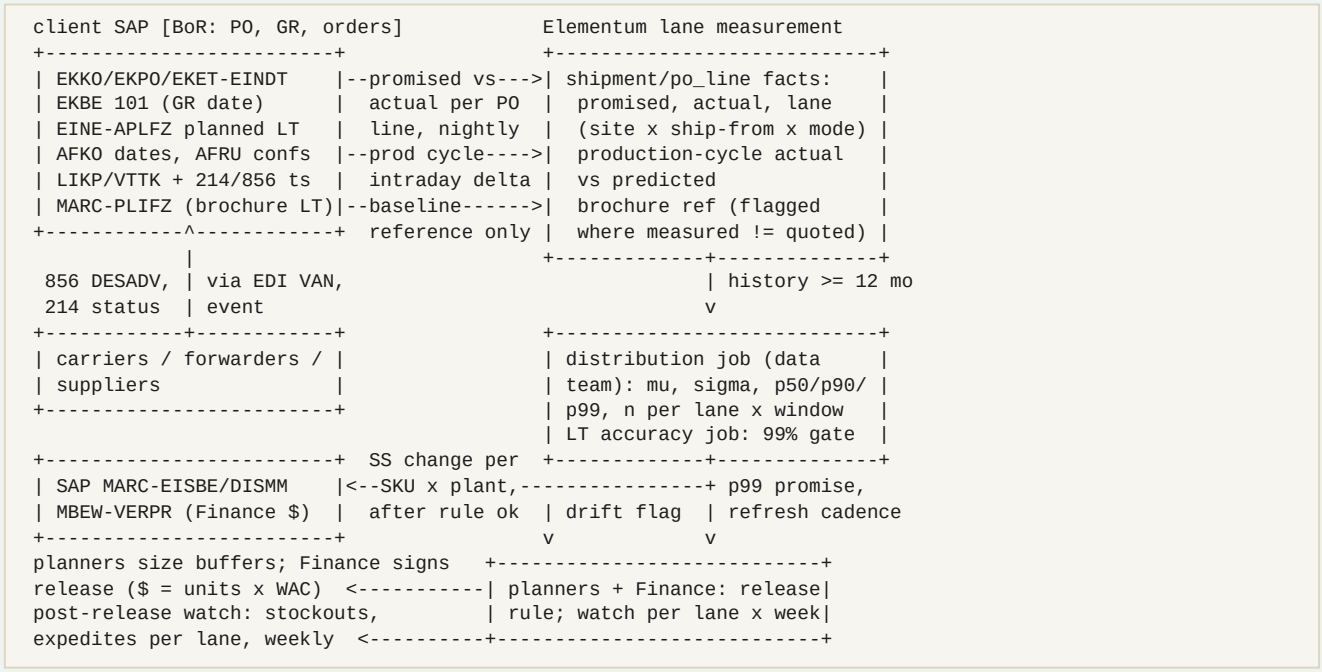

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Lead-time parameters	brochure folklore	measured distributions, 200 lanes	record
2	Lead-time accuracy	unmeasured	99% at p99	record
3	Inventory	brochure-sized	580K units / ~$1.5M released one-time	record pair
4	Stockouts on released lanes	—	0 in the watch window	record
5	Late arrivals	~10%	~1% at the 99% bar	record; volumes illustrative

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Unit value	`$1,500,000 / 580,000 = $2.59/unit`	derived from the record pair; low-value components	≈$2.59/unit
2	Carry on the release	`$1,500,000 × 20% = $300,000`	all-in carry (benchmark 15–25%)	≈$0.3M/yr
3	Late reduced	`10,000 × 10% = 1,000 before; 10,000 × 1% = 100 after; 1,000 − 100 = 900 fewer late`	volumes illustrative; the 99% is record	900 fewer late/yr
4	Expedites avoided	`900 × 10% = 90 expedited; 90 × $3,000 = $270,000`	expedited share and premium modeled	≈$0.3M/yr
5	Total recurring	`0.3 + 0.3 = $0.6M`	modeled; never added to S6's $2M	≈$0.6M/yr

SOLUTION FLOW — THE SYSTEM & DATA MAP

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Carrying rate (benchmark)	15% → $0.23M	20% → $0.30M	25% → $0.38M
Late share before p99 (illustrative)	5% → 400 fewer	10% → 900 fewer	15% → 1,400 fewer
Share of late arrivals expedited (illustrative)	5%	10%	15%
Expedite premium (benchmark)	$2K → $0.04M	$3K → $0.27M	$5K → $1.05M
Total modeled $/yr	≈$0.3M	≈$0.6M	≈$1.4M

RELEASE-DECISION DESIGN — POINT ESTIMATE VS UPPER BOUND; WHAT "99% ACCURACY" CAN MEAN (EXTRA TABLE)

The record is the rule — measured per-lane distribution, p99 promise, 99% accuracy gate, fat tails kept, Finance signs. The statistics below are my design arithmetic on illustrative lanes. VERIFY-WITH-RAJESH what the program did on thin lanes and which accuracy definition it used.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Brochure buffer	`z·d·σ_L = 2.33 × 500 × 5 = 5,825`	brochure σ 5 (illustrative); z = 2.33 (toolkit)	5,825 units
2	Reliable lane, point estimate	`2.33 × 500 × 1.2 = 1,398; release 5,825 − 1,398 = 4,427`	measured σ 1.2 (illustrative)	release 4,427
3	Standard error of σ̂	`σ ÷ √(2(n − 1)): n = 50 → 1.2 × 0.1010 = 0.121; n = 400 → 1.2 × 0.0354 = 0.042`	large-sample approximation	10.1% (n = 50) · 3.5% (n = 400)
4	95% upper bound on σ	`n = 50: 1.2 × (1 + 1.96 × 0.1010) = 1.44; n = 400: 1.2 × (1 + 1.96 × 0.0354) = 1.28`	one lane, illustrative n	1.44 · 1.28
5	Buffer on the upper bound	`n = 50: 2.33 × 500 × 1.438 = 1,675; n = 400: 1,495`	design arithmetic — not the record	1,675 · 1,495 units
6	Winner's-curse cost	`n = 50: 1,675 − 1,398 = 277 units × $2.59 = $717`	$2.59 = $1.5M ÷ 580K (record pair)	277 units ≈ $717 held back
7	Implied cost of a late day (p99)	`carry/day = 500 × $2.59 × 20% ÷ 365 = $0.71; Cu = 99 × $0.71 = $70`	critical ratio 0.99 ÷ 0.01	p99 justified above $70 per shortage-day
8	Accuracy as a ratio, per shipment	`|21 − 34| ÷ 34 = 38.2% → score 61.8%`	example lane (secondary source)	cannot be 99% — read as coverage or p99-match

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

"The measured result is five hundred eighty thousand units, about a million and a half dollars of safety stock, released at ninety-nine percent lead-time accuracy with zero stockouts on the watch; that is record and Finance signed it. What recurs around it I model at roughly six hundred thousand a year: about three hundred thousand in carrying cost on capital we no longer hold, and about three hundred thousand in expedites we no longer pay because the promise sits at the ninety-ninth percentile instead of a brochure number. The release and the accuracy are measured; the two recurring pieces are my model on benchmark carrying and expedite rates, and I never add this to the two million from the forecast program."

> **If challenged — the full answers.**
>
> **The expedite number is the softest**
>
> It assumes ten thousand shipments a year on the two hundred lanes and that one late arrival in ten forced an expedite before p99; to firm it I would pull the expedite ledger by lane for the year before and after the release and compare directly.
>
> **Twenty percent carrying cost is high**
>
> Fifteen to twenty-five is the textbook range and I use the middle; capital alone is eight to twelve, so if Finance wants capital only the carry is about a hundred and fifty thousand and I would say that instead.
>
> **Why is the million and a half not an annual saving**
>
> Because it is a one-time working-capital release, booked once as a signed planning act; what recurs is the carry and the avoided expedites, and I would rather be right at six hundred thousand a year than wrong at a million and a half.

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE WITH S8

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Tell me about a time you went deeper than the request.	Dive Deep	A "variability report" reframed as a promise-and-buffer policy; mean, spread and tail per lane from actuals; p99 defined cumulatively.	Do not claim to have built the distributions — the data team did, to my requirement.
Tell me about a time the data contradicted conventional wisdom.	Are Right, A Lot	Brochure values vs measured lanes; one right-skewed lane where the average hid the tail; planning chose p99 on the asymmetry.	S10 (Austria — "the noise said carriers") is the bar raiser's; do not use it here.
Tell me about a time you held a standard under pressure.	Insist on the Highest Standards	No release below 99% lead-time accuracy; Finance's push for a broader release answered with the rule they signed.	Do not frame Finance as the obstacle; the exception was in their rule.
How do you set safety stock / service levels?	Functional — placement policy	Two error signals (forecast, lead time), measured at the lane × SKU grain; policy by cost asymmetry; release by rule with a watch window; drift flags.	Never present the formula as a program artifact — MIT toolkit illustration.
What did you refuse to do?	Have Backbone	Averaging away a tail; endorsing a cut below 99%; a blanket release — all written into the act before anyone asked.	Keep the $2M (S6) out of this answer.
How did you make Finance comfortable releasing capital?	Earn Trust	Finance agreed the release rule in the same room as planning signed the policy — before any cut; signed each lane; the watch armed first.	No annualized $1.5M — it is a one-time release.

BEHAVIORAL PACK NEW — FOUR QUESTIONS THIS STORY ANSWERS, FOUR SEPARATE 90-SECOND ANSWERS (EACH FROM A DIFFERENT MOMENT OF THE STORY)

Q1 **Tell me about a time you went deeper than the request.** DIVE DEEP

Open (first two sentences): The ask was a “lead-time variability report.” I turned it into a parameter question: what number is the plan actually using, and how wrong is it?

STAR (≈90 s): Situation: a six-site manufacturer’s logistics manager wanted a report; inventory was sized on carrier-brochure lead times with variability unmeasured. Task: decide whether a report was the deliverable. Action: I reframed it as a parameter problem, scoped 200 lanes by site, lane and mode, wrote the success criteria — measured lanes replace brochures, and 99% lead-time accuracy before any cut — and had the data team build per-lane distributions. Result: planning chose a p99 promise and 580K units, about $1.5M, came out with zero stockouts.

Land this number: 200 lanes; 99% lead-time accuracy; 580K units / ~$1.5M, 0 stockouts. · **Pivot to NACF:** NACF inbound lead-time variability by vendor lane is the same “report” that is really a parameter. · **Do NOT say:** Do not say the data team’s distributions were mine; I owned the requirement, the policy and the release rule.

Q2 **Tell me about a time you put the customer’s cost ahead of your own team’s metric.** CUSTOMER OBSESSION

Open (first two sentences): The customer was the production line. A released unit of buffer that causes a line-down is worse than a unit never released.

STAR (≈90 s): Situation: carrying cost pushed to cut buffer; the line-down cost sat in another budget. Task: make the asymmetry visible. Action: I showed it lane by lane — an extra day of cover on the example lane costs about $0.71; a day of shortage costs far more — and let planning choose the quantile; they chose p99. On reliable lanes p99 still released buffer; on fat-tail lanes the buffer stayed. Result: zero stockouts across the released lanes.

Land this number: Zero stockouts (record); p99 on 200 lanes. · **Pivot to NACF:** Placement trades FC buffer cost against a missed promise the same way. · **Do NOT say:** Do not say planning was forced — say they chose with the asymmetry in front of them.

Q3 **Tell me about a time you got a finance partner to sign a risky decision.** EARN TRUST

Open (first two sentences): Finance signed each lane because the exception was written into the rule before anyone asked.

STAR (≈90 s): Situation: releasing safety stock is irreversible in practice. Task: a rule Finance could audit. Action: below 99% lead-time accuracy, no release; fat tails keep their buffer; Finance signs per lane; a stockout-and-expedite watch from day one. Result: $1.5M of working capital released, Finance-signed, no stockout in the watch window.

Land this number: 580K units / ~$1.5M (record, one-time). · **Pivot to NACF:** NACF WOC changes need a pre-signed exception clause too. · **Do NOT say:** Do not call the $0.6M recurring a result — it is modeled.

Q4 **Tell me about a process you designed that someone else now owns.** OWNERSHIP

Open (first two sentences): I designed the promise policy and the release rule as a signed planning act; planning re-applies it on its own refresh.

STAR (≈90 s): Situation: a one-off analysis decays into a new brochure. Task: leave a process, not a project. Action: drift flag per lane — p99 recomputed on refresh, the buffer decision re-opens if accuracy falls — and the watch became a standing report owned by planning. Result: the promise stays honest after I leave.

Land this number: Drift flag per lane; standing report owned by planning. · **Pivot to NACF:** Every NACF parameter I touch gets a drift flag and an owner. · **Do NOT say:** Do not say I run it today.

SAME STORY, THREE ANGLES NEW — THREE DIFFERENT OPENERS, HEADLINE METRICS AND LPS FROM THE SAME FACTS

(I) DATA / ANALYTICAL

LP: Dive Deep

Open: “Planning to the slow day, not the average.”

Headline metric: p99 per lane; 99% lead-time accuracy on 200 lanes

- Cumulative p99, not mean + 2.33σ — the normal shortcut understated one skewed lane by 3.4 days.
- Winner’s curse on thin lanes: size on the upper bound.
- Accuracy definition: coverage or p99-match.
- Reliable lane release 4,427; fat tail kept.

(II) CONFLICT / INFLUENCE / BACKBONE

LP: Customer Obsession; Earn Trust

Open: “Finance signed each lane because fat tails kept their buffer.”

Headline metric: 580K units / ~$1.5M, zero stockouts

- Asymmetry shown lane by lane.
- Planning chose p99.
- Exception in the rule before the ask.
- Release is one-time working capital.

(III) FAILURE — LEARNING — WHAT I WOULD DO DIFFERENTLY

LP: Learn and Be Curious

Open: “I would put the interval on the page next to every p99.”

Headline metric: p99 interval open-ended above at n < 330

- The record carries no window length — I do not invent one.
- S8a and S8c are the interval and validation work.
- Thin lanes: cohort pooling or a longer window.
- VERIFY-WITH-RAJESH the program’s thin-lane rule.

TRAP DRILLS NEW — THE THREE NASTIEST FOLLOW-UPS A STATISTICALLY RIGOROUS INTERVIEWER THROWS

T1 “Define 99% lead-time accuracy — what tolerance does it allow?”

The numbers: Ratio form: 1% × 5 d = 0.05 d; 1% × 30 d = 0.3 d. Per shipment vs a p99 promise: |21 − 34| ÷ 34 = 38.2% → 61.8%. Coverage form: 1 shipment in 100 beyond the promise.

Say exactly: “Written as one minus the absolute miss over the promise, one percent is a twentieth of a day on a five-day lane and a third of a day on a thirty-day lane — but against a p99 promise the average shipment misses by about thirty-eight percent, so I read ninety-nine as coverage: ninety-nine of a hundred shipments inside the promise. I would confirm which definition the record uses before I quote a tolerance.”

T2 “Why p99 and not p95 — what is that buffer worth?”

The numbers: Carry per day of cover = 500 × $2.59 × 20% ÷ 365 = $0.71; p99 ⇔ a shortage-day worth > 99 × = $70; p95 ⇔ > $13.

Say exactly: “A p99 promise says a shortage day costs ninety-nine carrying days — about seventy dollars on that lane — and a line-down clears that by orders of magnitude; I showed planning the asymmetry lane by lane and they chose p99.”

T3 “You released the lanes with the smallest measured σ. Isn’t that a selection effect?”

The numbers: σ̂ standard error = σ ÷ √(2(n−1)) = 10.1% at n = 50; upper-bound σ 1.44; buffer 1,675 vs 1,398; 277 units held back.

Say exactly: “Yes, partly — a lane picked for a small measured spread is partly a lucky draw; on a fifty-shipment lane sizing on the upper bound holds back about two hundred seventy-seven units of the four thousand four hundred I would otherwise release. I would show that adjustment next to every release.”

S8a — Elementum — actual-vs-planned lead-time distribution analysis: the brochure was wrong three ways — 3 days short on the mean, twice-too-wide on the spread, 16 days short on the tail NEW

LPs this story serves here: Dive Deep (primary — plan vs actual at the shipment grain) · Are Right, A Lot (rank, don't fit) · Insist on the Highest Standards (a "99%" plan that held 96.5% is not a 99% plan) · Earn Trust (the carrier's own scans, not my opinion)
Process family: Plan / Source seam — inbound lead-time parameter diagnosis before any buffer or policy change

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH NEW

- **Dive Deep** — I compared plan to actual at the shipment grain on three axes — location, spread, tail — before changing a single parameter; 240 of 400 shipments ran slower than the brochure.
- **Are Right, A Lot** — I ranked the shipments instead of fitting a bell curve; the curve's "99%" plan held 96.5% — 14 of 400 shipments ran past it — and the ranked p99 held 99%.
- **Insist on the Highest Standards** — I refused to publish a p99 that carried its own error: a plan statistic had to be distribution-free and come with its sampling uncertainty.
- **Earn Trust** — I showed planners and commercial the carrier's own scans on one lane — brochure 18, mean 21, p99 34 — so the argument was the data, not my say-so.

Honesty label. I owned the question, the comparison design and the plan statistic; the data team built the per-lane distributions to my requirement. The 18 / 21 / σ 4 / p99 34 / n≈400 lane is the loop packet's example lane (secondary source — the master packet carries "18d brochure" in its crosswalk and "lane-cohort counts are not in the record"); the ERP default σ of 8 days and the 7-day manual pad are that packet's illustrative inputs. Say "illustrative inputs, real outcomes": the record is 200 lanes, 99% lead-time accuracy at the p99 promise, 580K units / ~$1.5M released. VERIFY-WITH-RAJESH that the example-lane numbers are the ones you are comfortable quoting.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. The six-site manufacturer's safety stock kept growing and nobody could say why. Planning ran on carrier-brochure lead times — on my example lane, 18 days — plus a manual week of pad that every planner added. Task. Before touching a parameter I owned one question: how, exactly, was the planned lead time wrong? Action. I pulled about a year of shipment history on the lane — roughly 400 shipments — and compared plan to actual three ways. Location: the actual mean was 21 days, three days longer than the brochure, fifteen standard errors — not noise — and 240 of 400 shipments, 60%, ran slower than the number in the system. Spread: the ERP's default assumed an 8-day standard deviation; measured, it was 4 — wrong in the opposite direction, which is why planners had padded by hand. Tail: a bell curve from that mean and spread puts the 99th percentile at 30.3 days, but 14 of the 400 shipments ran longer — a "99%" plan that actually held 96.5%. Ranking the shipments puts it at 34. Result. Primary metric: shipments late against the plan on that lane, 60% → 1%, planned lead time 18 → 34 days; at program level, lead-time accuracy 99% on 200 lanes — record. The example lane is the pattern, not the headline.

20-SECOND VERSION NEW

The planned lead time was wrong in three directions at once — the mean was 3 days short, the ERP's spread was twice the real one, and the tail was 16 days out; I measured all three on the carrier's own scans and planned to the ranked p99, not a bell curve.

NACF BRIDGE — ONE SENTENCE

Every NACF inbound plan is a promised date; I would run the same plan-vs-actual on appointment and ASN dates versus receive scans, by vendor lane, before anyone resizes a buffer — location, spread, tail.

SITUATION / TASK — THE PROBLEM SPACE

S — Elementum, the same six-site manufacturer. Buffers kept growing, service was still shaky and nobody could explain why. Inventory planning ran on carrier-brochure lead times (18 days on the example lane) and every planner added an informal week of pad. The risk of doing nothing: working capital grows every quarter and every stockout triggers more padding — a wrong number plus panic.

T — Own the diagnosis: characterize how the planned lead time was wrong — bias, spread, tail — with the uncertainty on each statement, so the later policy (S8) and the formula redesign (S8b) stand on measured facts. Scope: 200 lanes by site, lane and mode; the example lane is the busy one.

Baselines on the table: planned lead time = brochure (18 d on the example lane) · actual mean 21 d · 60% of shipments slower than plan · ERP default σ_LT = 8 d (never measured) · manual pad 7 d × 500 units/day = 3,500 units on the lane · no lead-time-accuracy measurement existed.

ACTION — FIVE GATED PHASES

- **Discovery** — agreed with planning and logistics that the question was “how is the parameter wrong,” not “write a variability report”; chose the example lane because it had the history (≈8 shipments a week for a year). Exit bar: the comparison design — three tests, one lane — accepted before any number was shown.
- **Plan & Design** — requirement to the data team: promised date (PO-line schedule) vs actual receipt per shipment, keyed by lane = site × ship-from × mode, 12+ months so every season is in the sample; outputs mean, σ, p50 / p90 / p99, n and the late share against the plan in force. Exit bar: data team accepts the spec; planning agrees which plan statistic is on trial (mean, brochure + pad, normal p99, ranked p99).
- **Build & Test** — data team built the lane file; I owned the comparison: bias with its standard error, late share with a binomial interval, σ against the ERP default, then the four candidate plans scored on the same 400 shipments. Exit bar: the candidate table reproduces on a second pull; the ranked p99 reproduces the “99%” by construction and its sampling interval is printed beside it.
- **Cutover & Go-Live** — the finding went to planners as one lane, three numbers — brochure 18, mean 21, p99 34 — then the same three tests per lane for all 200; the plan statistic moved to the ranked p99 under the release rule (S8) and the formula (S8b). Exit bar: planning signs the plan statistic; the old brochure stays in the master as a labeled reference only.
- **Hypercare / Close** — drift flag per lane (p99 recomputed on refresh; review if the tail or the spread moves) and a standing plan-vs-actual page owned by planning. Exit bar: the page refreshes without me; thin lanes carry their interval on the page so nobody reads a max as a quantile.

Influence and ownership. I owned the question, the comparison and the plan statistic; the data team built the distributions; planners owned the parameters and the buffers; Finance and planning signed the policy that used it. The conflict was commercial: quoting 34 days where the brochure said 18 — answered with the number that decided it: a fast promise missed 60% of the time costs expedites and trust; the honest date costs only optics, and where speed truly mattered we fixed the lane, not the number.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY

- **%** — shipments late against the plan on the example lane 60% (brochure) → 1% (ranked p99); program level: lead-time accuracy 99% on 200 lanes at the p99 promise (record).
- **Time** — planned lead time on the example lane 18 → 34 days: the plan now says what 99 of 100 shipments do.
- **#** — 200 lanes measured by site, lane and mode; 580K units / ~$1.5M released later under the signed rule (record, one-time — S8).
- **$** — on the example lane only: ≈$9.0K a year modeled (carry on the 3,500-unit pad + expedites on late arrivals) — an illustrative lane, never scaled by 200 and never added to S8’s ≈$0.6M or S6’s $2M.
- **Quality** — every plan statistic reported with n and an interval; the max of a thin lane is never presented as its p99.

L6 LEVEL EVIDENCE — what the interviewer pattern-matches against the Amazon L6 functional rubric

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	No agreed definition of “how wrong is the planned lead time”; I defined it as three tests — location, spread, tail — and the unit of analysis (the shipment on a lane).
Scope & influence	Planners, logistics, commercial, Finance and a data team that did not report to me; the commercial pushback on 34 vs 18 resolved by the 60%-late number.
Execution	Chose a distribution-free plan statistic over a convenient formula and carried its interval; sequenced diagnosis (this story) before policy (S8) before formula (S8b).
Impact	99% lead-time accuracy on 200 lanes (record); the diagnosis is what made 580K units / ~$1.5M releasable without a stockout.
Process improvement	A standing plan-vs-actual page and drift flag per lane — the parameter can no longer decay into a new brochure.
Complexity	Skewed tails, thin lanes, seasonality inside a 12-month window, and a normal-fit shortcut that looks right and holds 96.5%.
Root cause	The root cause was the planning parameter, not the carrier: 60% of arrivals were “late” against a number the carrier never measured.

THE FIVE FACETS NEW — data analysis · solution design · math & data logic · implementation · probe questions; each labeled so the interviewer can see all five are present

1 · Data analysis	Data: shipment × lane (site × ship-from × mode), promised date (PO-line schedule) vs actual receipt, 12+ months; joins PO line → goods receipt → lane key; cuts by lane, mode, site, quarter. Revealed: bias +3 d (t = 15), 60% of shipments slower than plan, ERP σ 8 vs measured 4, normal-fit p99 holds 96.5%.
2 · Solution design	Options: plan to the mean · brochure + planner pad · normal-fit p99 · ranked (empirical) p99. Chosen: ranked p99 — distribution-free, defensible to the tail the business cares about; why: it is the only candidate whose coverage does not depend on an assumed shape.
3 · Math & data logic	Math: bias = 21 − 18 = +3.0 d; SE = 4/√400 = 0.20; t = 15.0 · late share 240/400 = 60% (Wilson 95% [55.1%, 64.7%]) · normal p99 = 21 + 2.33 × 4 = 30.32, 14/400 beyond → 96.5% · ranked p99 = t(⌈0.99 × 400⌉) = t(396) = 34 d · order-statistic 95% interval t(392)…t(400).
4 · Implementation	Implementation: spec → data team → lane file → comparison → planning sign-off → plan statistic moves to the ranked p99 under the S8 release rule; drift flag + refresh cadence; thin lanes print their interval. Risk: thin lanes — handled by cohort pooling or a longer window (VERIFY-WITH-RAJESH what was actually done).
5 · Probe questions	Probe questions: n and representativeness · +3 d noise vs signal · interval on a p99 from 4 observations · seasonality · thin lanes · why rank not fit — all answered with numbers below and in the Trap Drills.

PROBING — CHALLENGE Q&A TUNED TO A STATISTICIAN

> **Analytics — n = 400 on one lane. Is that representative of 200 lanes?**
>
> No, and I say so. It is the busiest lane, about eight shipments a week. The master’s illustrative volume is about 10,000 shipments a year across 200 lanes — roughly 50 on an average lane — so the example shows the mechanism and the same three tests ran per lane. At n = 50 the order-statistic interval for the p99 is open-ended above: t(48) up to “unbounded” — the maximum is only a lower bound, which is why thin lanes need a longer window or cohort pooling. VERIFY-WITH-RAJESH what the program did for thin lanes.

> **Analytics — Is a three-day difference statistically meaningful or just practically meaningful?**
>
> Both. Standard error of the mean is 4 ÷ √400 = 0.20 day, so the 95% interval on the actual mean is 21 ± 0.39 — the brochure sits fifteen standard errors away. Practically, 3 days × 500 units a day is 1,500 units of exposure per cycle that the plan did not know about.

Analytics — Your p99 is the 396th of 400. What is the confidence interval?

Wide, and I print it: with n = 400 the 95% interval for the true p99 runs from the 392nd-ranked shipment (between 31 and 34 days on this lane) to the slowest one (35 or more). In-sample coverage of the ranked plan is 99% by construction; the honest sampling interval on that coverage is 97.5%–99.6% — which is why I validated on a held-out quarter (S8c) and put a drift flag on every lane.

Analytics — Why not just mean + 2.33σ?

Because lead-time tails are right-skewed and the shortcut understates them. On this lane it gives 30.32 days; 14 of 400 shipments, 3.5%, ran longer, so a “99%” plan delivered 96.5%. On the whiteboard sample — 20 shipments, mean 12.5, σ 2.64 — the normal p99 is 12.5 + 2.33 × 2.64 = 18.65 against a ranked 22: about 3.4 days short, the canon figure.

Analytics — What about seasonality in the window?

The window was twelve months or more, so every quarter is inside the sample and the p99 prices the slow season rather than ignoring it. The test I would add is the quarterly cut: the +3-day bias should carry the same sign in all four quarters before I call it a parameter error rather than one bad season. The record does not carry that cut. VERIFY-WITH-RAJESH

Shadow / closing — What would you do differently?

Lead with the thin lane, not the busy one — show the interval first. A p99 from fifty shipments is a maximum with a label on it, and the plan page should say so.

BUSINESS IMPACT MODEL — WHAT THE WRONG PLANNED LEAD TIME COST (EXAMPLE LANE, MODELED)

```
Planned lead time wrong (brochure 18 d)
+- Location error: mean 21 vs plan 18  -> 60% of shipments late vs plan (240 / 400)
+- Spread error: ERP sigma 8 vs measured 4 -> wrong the OTHER way -> planners pad by hand
+- Tail error: normal p99 30.3 holds 96.5%; ranked p99 = 34 holds 99%
+- Consequence A (stock): 7-day pad x 500 units = 3,500 units held to cover the brochure
+- Consequence B (flow): late arrivals vs the planning date -> expedites
+- Fix: plan statistic = ranked p99 (distribution-free) + interval + drift flag
```

DRIVER	BASELINE	AFTER	$/YR (LANE)	BASIS
Planned lead time	18 d (brochure)	34 d (ranked p99)	—	loop-packet example lane (secondary)
Shipments late vs plan	28 of 400 vs the 25-d planning date (7%); 240 of 400 vs the 18-d brochure	4 of 400 (1%)	—	loop-packet example lane
Carry on the manual pad	3,500 units × $2.59 = $9,065 held	pad not needed	$1,813	modeled (20% all-in carry; benchmark 15–25%)
Expedites on late arrivals	28 × 10% × $3,000	4 × 10% × $3,000	$7,200	modeled (10% share and $3K premium illustrative)
Total, this lane	—	—	**≈$9.0K**	illustrative lane — never scaled ×200, never added to S6/S8

If challenged. *“Multiply by 200.”* — “No: lanes differ by two orders of magnitude in volume; the program-level recurring value is S8’s ≈$0.6M on its own inputs, and this lane is the mechanism, not the sample.”

THE MATH — STEP-BY-STEP DERIVATION

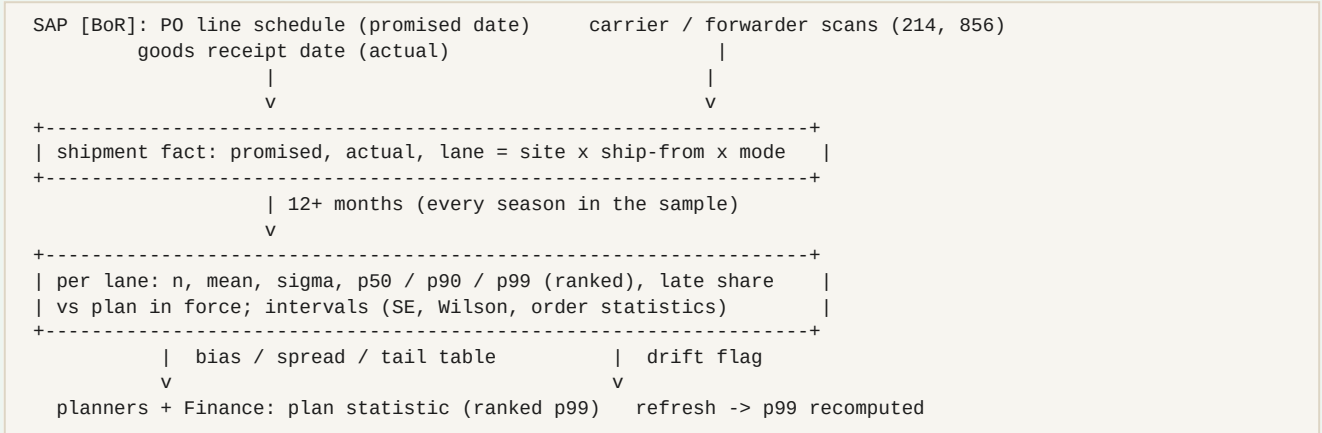
Table 1 — before: how the plan was wrong (example lane, n ≈ 400).

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Sample	`n ≈ 400 (≈ 8 shipments/wk ≈ one year)`	loop-packet example lane (secondary) — a busy lane; average lane ≈ 50 (master, illustrative)	n = 400
2	Location error	`mean − brochure = 21 − 18 = +3.0 d (3 ÷ 18 = +16.7%)`	brochure 18, measured mean 21 (example lane)	+3.0 d
3	Is it noise?	`SE = σ/√n = 4/√400 = 0.20 d; t = 3.0/0.20 = 15.0; 95% CI of mean = 21 ± 1.96 × 0.20 = [20.61, 21.39]`	measured σ = 4 d	t = 15.0 — not noise
4	Late vs brochure	`240 / 400 = 60.0%; Wilson 95% [55.1%, 64.7%]`	counts of shipments slower than 18 d	60% late
5	Spread error	`ERP σ = 8 vs measured 4 → ratio 2.0, variance ratio 4.0; CI of σ ≈ 4 ± 1.96 × 4/√(2 × 399) = [3.72, 4.28]`	ERP default 8 d (illustrative); large-sample approximation	8 is far outside the interval
6	Tail error — bell curve	`21 + 2.33 × 4 = 30.32 d; 14 / 400 = 3.5% beyond → coverage 96.5%`	z = 2.33 (99%, toolkit label)	a “99%” plan that holds 96.5%
7	Tail error — vs brochure	`ranked p99 − brochure = 34 − 18 = 16 d`	ranked p99 = t(396)	16 d short on the tail
8	The manual patch	`7 d × 500 units/day = 3,500 units`	pad and demand rate illustrative	3,500 units of pad

Table 2 — the fix: four candidate plans scored on the same 400 shipments.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Plan = mean	`21 d; shipments slower: 160 of 400`	counts from the lane file (loop packet)	serves 60.0%
2	Plan = brochure + planner pad	`18 + 7 = 25 d; slower: 28 of 400`	pad illustrative	serves 93.0%
3	Plan = normal-fit p99	`21 + 2.33 × 4 = 30.32 d; slower: 14 of 400`	assumes a bell curve	serves 96.5% — not 99%
4	Plan = ranked p99	`position ⌈0.99 × 400⌉ = 396 → t(396) = 34 d; slower: 4 of 400`	distribution-free (record definition)	serves 99.0% in-sample
5	Interval on the ranked plan’s coverage	`4/400 late → Wilson [0.39%, 2.54%] late → coverage [97.5%, 99.6%]`	binomial; n = 400	in-sample 99% is not a guarantee
6	Interval on the p99 itself	`95% interval t(392)…t(400) (coverage 96.1%); n = 50 → t(48)…open; n = 100 → t(97)…open; n = 1,000 → t(983)…t(996)`	exact binomial order-statistic interval	thin lanes cannot bound a p99 from above
7	Whiteboard sample (n = 20)	`mean 12.5, σ 2.64; ranked p50 = 12, p90 = 14, p99 = 22; normal p99 = 12.5 + 2.33 × 2.64 = 18.65; gap = 22 − 18.65 = 3.35 ≈ 3.4 d`	values 9,10,11×5,12×6,13×3,14×2,15,22 (illustrative)	normal understates by ≈3.4 d (canon)

Table 3 — after: the metric, before → after.



STEP	METRIC	BEFORE	AFTER	BASIS
1	Planned lead time (example lane)	18 d (brochure)	34 d (ranked p99)	example lane (secondary)
2	Shipments late against the plan	60% vs brochure (28 of 400 = 7% vs the 25-d planning date)	1% (4 of 400)	example lane
3	Lead-time cover in the plan (plan − mean)	18 − 21 = −3 d (plan below the mean)	34 − 21 = +13 d	derived; feeds S8b
4	Spread used in planning	8 d (ERP default, unmeasured)	4 d measured, per lane	illustrative default
5	Lead-time accuracy, 200 lanes	unmeasured	99% at the p99 promise	record

Table 4 — the dollars, every multiplication shown (example lane, modeled).

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Pad inventory	`7 d × 500 units/day = 3,500 units; 3,500 × $2.59 = $9,065`	$2.59 = $1.5M / 580K (derived record pair)	$9,065 of capital on the pad
2	Carry on the pad	`$9,065 × 20% = $1,813/yr`	benchmark 15–25% all-in	≈$1,813/yr
3	Expedites before	`28 late × 10% × $3,000 = $8,400`	late vs the 25-d planning date; share and premium illustrative	$8,400/yr
4	Expedites after	`4 late × 10% × $3,000 = $1,200`	late vs the 34-d plan	$1,200/yr
5	Expedites avoided	`$8,400 − $1,200 = $7,200`	row 3 − row 4	$7,200/yr
6	Lane total	`$1,813 + $7,200 = $9,013`	modeled, one illustrative lane	≈$9.0K/yr — never × 200

Dollar basis labels: the lane statistics are the loop packet's example lane (secondary); every dollar is modeled on illustrative inputs; the record is the 99% / 200 lanes / 580K units / ~$1.5M quartet in S8.

SOLUTION FLOW — THE PLAN-VS-ACTUAL ANALYSIS PIPELINE

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Shipments on the lane (n) — p99 interval	n = 50 → t(48)…open	n = 400 → t(392)… t(400)	n = 1,000 → t(983)… t(996)
Carry rate on the pad	15% → $1,360	20% → $1,813	25% → $2,266
Expedite share of late arrivals	5% → $3,600 avoided	10% → $7,200	15% → $10,800
Lane total (modeled, one lane)	≈$5.0K	≈$9.0K	≈$13.1K

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

“On one busy lane the brochure said eighteen days; the actual mean was twenty-one, a three-day gap that is fifteen standard errors wide, and sixty percent of shipments ran slower than the number in the system. The system’s default spread was eight days; measured, it was four. A bell curve would have promised a ninety-ninth percentile of thirty point three, and fourteen of four hundred shipments ran past it; ranking the shipments gives thirty-four, which held ninety-nine percent. The record is ninety-nine percent lead-time accuracy on two hundred lanes. The lane is an example and the dollars around it are my model on illustrative inputs — about nine thousand a year on that one lane, and I never multiply it by two hundred.”

If challenged — the full answers

The lane is the example, not the data. “The program-level result is the record — 200 lanes, 99%, 580K units, about $1.5M. The lane shows how I got there; its counts are the loop-packet example and I say so.” The interval is wide. “Yes. With 400 shipments the p99 rests on the top four; I print the interval and validate out of sample in S8c. With 50 shipments I would not call a maximum a p99.” The dollars are small. “One lane, modeled, on purpose — I would rather show the arithmetic than a program-wide number I can’t derive.”

BEHAVIORAL PACK NEW — FOUR QUESTIONS THIS STORY ANSWERS, FOUR SEPARATE 90-SECOND ANSWERS (EACH FROM A DIFFERENT MOMENT OF THE STORY)

Q1 **Tell me about a time you dug into the data to find the real problem.** DIVE DEEP

Open (first two sentences): Buffers kept growing and nobody could say why, so I stopped collecting opinions and pulled the shipment scans on our busiest lane. A year of history, about 400 shipments, planned date against actual receipt.

STAR (≈90 s): Situation: the plan said 18 days on that lane and every planner padded a week by hand. Task: find how the number was wrong before anyone changed a parameter. Action: I compared plan to actual three ways — the mean was 21 days, three days late and fifteen standard errors from the brochure; the ERP’s assumed spread was 8 days against a measured 4; and the tail ran to 34 days. I showed it as the carrier’s own data on one lane. Result: planners stopped debating whose buffer was right and agreed the parameter was the problem; that became the p99 promise and the 580K-unit release.

Land this number: 60% of shipments slower than the brochure (240 of 400); mean 21 vs 18 — t = 15. · **Pivot to NACF:** NACF inbound runs on promised dates — ASN ETAs and appointment slots; the same plan-vs-actual by vendor lane is the first diagnostic I would run. · **Do NOT say:** Do not say I built the distributions — the data team did, to my requirement; do not say “400 on every lane.”

Q2 **Tell me about a time the data contradicted what everyone believed.** ARE RIGHT, A LOT

Open (first two sentences): The belief was that the carrier was missing its transit times. The scans said the carrier was delivering in about 21 days and we were planning on 18.

STAR (≈90 s): Situation: service was shaky and the room's theory was carrier performance — re-contract, escalate. Task: decide whether this was carrier management or planning. Action: I did not argue; I compared actual to the planned number and to the ERP's assumed spread; the options ranked themselves — the carrier was consistent, our parameter was wrong. Result: the fix moved to planning parameters, not carrier contracts, and the lane held 99% at the ranked p99.

Land this number: Mean 21 d vs plan 18 d; p99 34 d. · **Pivot to NACF:** In NACF terms: before blaming a carrier or a vendor for dock chaos, check whether the inbound plan's lead-time parameter was ever right. · **Do NOT say:** Do not imply the carriers were perfect — say the distribution had a tail; the point is the plan ignored it.

Q3 **Tell me about a time you refused to accept a metric that looked good enough.**
INSIST ON THE HIGHEST STANDARDS

Open (first two sentences): A bell-curve p99 looked right — 30.3 days — and it was a "99%" plan that held 96.5%. I would not ship a 99% label on a 96.5% plan.

STAR (≈90 s): Situation: the standard shortcut, mean plus 2.33 standard deviations, was what the planning system and most analysts would use. Task: choose the plan statistic. Action: I scored four candidate plans on the same 400 shipments — mean 60%, brochure plus pad 93%, normal p99 96.5%, ranked p99 99% — and printed the sampling interval on the winner so nobody mistook in-sample for guaranteed. Result: the ranked p99 became the statistic; the interval is why I also ran a held-out quarter.

Land this number: 96.5% vs 99% — 14 vs 4 of 400. · **Pivot to NACF:** For NACF placement and WOC targets, the same discipline: name the service level, then check what the distribution actually delivers. · **Do NOT say:** Do not call 99% "guaranteed"; say in-sample by construction, interval 97.5–99.6.

Q4 **Tell me about a time you persuaded a skeptical group with data.** EARN TRUST

Open (first two sentences): Commercial hated the number — 34 days where the brochure said 18. I did not defend it; I showed them what 18 had cost.

STAR (≈90 s): Situation: commercial teams quote what the system says, and a longer date reads as slower. Task: get a defensible promise adopted without an organizational fight. Action: one lane, three numbers — 18 brochure, 21 mean, 34 p99 — and the price of the status quo: a fast date missed 60% of the time costs expedites and trust, the honest date costs only optics. Where speed genuinely mattered I offered to fix the lane, not the number. Result: planning signed the plan statistic and commercial stopped quoting the brochure.

Land this number: 60% late at the quoted date vs 1% at the plan. · **Pivot to NACF:** Amazon's promise engine faces the same trade at scale; I would lead with the cost of the missed promise, not the length of the date. · **Do NOT say:** Do not say commercial was wrong to want speed — say the lever was the lane, not the label.

SAME STORY, THREE ANGLES NEW — THREE DIFFERENT OPENERS, HEADLINE METRICS AND LPS FROM THE SAME FACTS

(I) DATA / ANALYTICAL

LP: Dive Deep

Open: “The brochure was wrong three different ways.”

Headline metric: t = 15 on the 3-day bias; 60% of shipments slower than plan

- Location: +3 d, SE 0.20 d, 15 standard errors.
- Spread: ERP σ 8 vs measured 4 — wrong the other way, hence the pad.
- Tail: normal p99 30.3 holds 96.5%; ranked p99 34 holds 99%.
- One lane, three numbers, the carrier’s own scans.

(II) CONFLICT / INFLUENCE / BACKBONE

LP: Have Backbone; Earn Trust

Open: “Commercial wanted to keep quoting 18; I would not put an 18 on a promise that failed 60% of the time.”

Headline metric: 60% late at the brochure date vs 1% at p99

- The objection was real: 34 reads slower than 18.
- I priced the status quo — expedites and trust — instead of arguing.
- Offered the lane fix where speed mattered.
- Planning signed the statistic; the brochure became a labeled reference.

(III) FAILURE — LEARNING — WHAT I WOULD DO DIFFERENTLY

LP: Learn and Be Curious

Open: “I led with the busiest lane because it had the data — and that was my analytical shortcut.”

Headline metric: n = 400 busy lane vs ≈ 50 on an average lane; p99 interval open-ended above at n = 50

- Honest limit: a thin lane’s max is not its p99.
- I would now show the interval first and pool thin lanes by cohort.
- The held-out quarter (S8c) and the drift flag were the backstops.
- VERIFY-WITH-RAJESH what the program actually did on thin lanes.

TRAP DRILLS NEW — THE THREE NASTIEST FOLLOW-UPS A STATISTICALLY RIGOROUS INTERVIEWER THROWS

T1 “Your p99 rests on four observations. How can that be a plan?”

The numbers: n = 400 → 95% interval t(392)…t(400); coverage interval 97.5%–99.6%; n = 50 → open-ended above; held-out quarter 99.1% (loop packet; S8c).

Say exactly: “It rests on the top four, and I print the interval — ninety-seven and a half to ninety-nine point six on coverage. That is why I validated on a held-out quarter and put a drift flag on every lane; on a thin lane I would not call a maximum a ninety-ninth percentile.”

T2 “How do you know the three-day gap is not one bad quarter?”

The numbers: SE 0.20 d; t = 15.0; window ≥ 12 months; the test I would add: same sign in all four quarterly cuts.

Say exactly: “Fifteen standard errors across a twelve-month window is not noise, but one bad quarter could still dominate it — the check is the quarterly cut, same sign in all four. The record doesn’t carry that cut and I would not claim it.”

T3 “What was the counterfactual — what would the plan have delivered if you had done nothing?”

The numbers: Brochure plan late 240/400 = 60%; brochure + pad 28/400 = 7% (93% served); ranked p99 4/400 = 1%.

Say exactly: “On the same 400 shipments the brochure plan was late sixty percent of the time and the brochure-plus-pad plan seven percent; the ranked p99 plan one percent — that is the counterfactual, shipment by shipment, with the interval.”

S8b — Elementum — safety-stock formula redesign: one formula nobody could defend plus a week of pad → two honest terms; one lane released 4,835 units, one lane took 1,383 in, 580K net NEW

LPs this story serves here: Invent and Simplify (primary — two terms replace a formula and a pad) · Have Backbone; Disagree and Commit (a rule that adds stock where the tail is fat) · Frugality (less stock, better service) · Ownership (a release rule someone owns after I leave)
Process family: Plan / Source seam — inventory-policy formula and release rule on top of the measured lane distributions (S8a → S8 → S8b)

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH NEW

- **Invent and Simplify** — I replaced "$z \cdot \sqrt{(LT \cdot \sigma_d^2 + d^2 \cdot \sigma_{LT}^2)}$ plus a week of pad" with two terms a planner can read — lead-time cover to the measured p99 and demand cover over the mean lead time.
- **Have Backbone; Disagree and Commit** — The rule I wrote cuts both ways — on a lane whose measured tail is fatter than the assumption it adds stock — and I kept it two-sided when a one-way cut would have been easier to sell.
- **Frugality** — Lane A went 12,937 → 8,102 units while late arrivals fell from 7-in-100 to 1-in-100: less stock and better service from one honest number.
- **Ownership** — The release was a signed planning act with a drift flag and a standing stockout-and-expedite report planning owns — the formula does not need me to keep working.

Honesty label. I owned the formula redesign, the two worked lanes and the release rule; planners owned the parameters and Finance signed each lane. Lane A (d = 500, σ_d = 150, brochure 18 d, ERP σ_{LT} = 8 d, measured mean 21 / σ 4 / p99 34) and Lane B (d = 200, σ_d = 80, brochure 24, measured mean 30 / σ 11 / p99 58) are the loop packet's worked lanes; the roll-up split — about 150 lanes releasing an average of 4,500 units, about 50 lanes adding an average of 1,900 — is the loop packet's illustrative decomposition. The record is the net: 580K units / ~$1.5M, zero stockouts.
VERIFY-WITH-RAJESH — the master and this packet's S8 say fat-tailed lanes' buffer was "kept"; the loop packet says about 50 lanes took stock in. Say "kept, and on the worst lanes raised" only if that is what happened.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. A six-site manufacturer's inventory buffers were set by a textbook formula fed an assumed lead-time swing of eight days that nobody had measured, plus a week of pad that every planner added by hand. Task. Redesign the buffer so it said what the lanes actually did, and write the rule for when capital could come out. Action. I took the formula apart: on the example lane, 97.5% of its variance came from that unmeasured eight-day swing — the formula was mostly measuring a guess. I replaced it with two terms: lead-time cover — units per day times the distance from the average lead time to the measured ninety-ninth percentile — and demand cover over the average lead time. The pad went to zero because the plan now held 99%. The rule cut both ways: release only where the measured spread was inside the assumption, and where the tail was fatter, keep or add. Result. Primary metric: safety stock on the example lane 12,937 → 8,102 units, 37% less, with late arrivals 7-in-100 → 1-in-100; the program released 580K units, about $1.5 million, with zero stockouts — record, one-time working capital.

20-SECOND VERSION NEW

I replaced a formula that was 97% an unmeasured guess, plus a hand-added pad, with two honest terms — cover to the measured p99 and demand cover — and a two-sided release rule: 580K units out net, zero stockouts.

NACF BRIDGE — ONE SENTENCE

The NACF version is the inbound booklet's INV-B: $SS = z \cdot \sigma \cdot \sqrt{LT}$ — I would show which of the two variance terms dominates before anyone moves a buffer, and I would write the release rule so it can raise a buffer as well as cut it.

SITUATION / TASK — THE PROBLEM SPACE

S — The same six-site manufacturer. Safety stock was the textbook form, $z \times \sqrt{(LT \cdot \sigma_d^2 + d^2 \cdot \sigma_{LT}^2)}$, with the brochure lead time and a σ_{LT} of 8 days that was the ERP's default, plus an informal manual pad of about a week per lane. Nobody could say which part of the buffer was protecting against demand and which against transit — and on the loud lanes the answer was always "add more."

T — Own the formula and the release rule: say what each unit of buffer is for, size it from the measured distribution (S8a), and release capital only where the measured evidence supported it — with the exception written into the rule before anyone asked.

Baselines on the table: Lane A buffer 12,937 units (25.9 days of demand) · pad 3,500 units uncounted in the ERP · 7-in-100 shipments late against the plan in force · no statement of what service level the buffer bought.

ACTION — FIVE GATED PHASES

- **Discovery** — took the ERP formula apart on one lane: the demand part contributed 405,000 to the variance, the lead-time part 16,000,000 — 97.5% of it an assumed number. Exit bar: planning and Finance agree the buffer is a parameter question, not a service-level argument.
- **Plan & Design** — two terms — lead-time cover $d \times (p99 - \text{mean})$ using the ranked p99 from S8a, and demand cover $z \times \sigma_d \times \sqrt{(\text{mean lead time})}$ — pad to zero; release rule: release only where the measured spread and tail are inside the assumption and lane accuracy holds; where they are not, the buffer stays or rises. Exit bar: Planning and Finance sign the rule's text, including the add-stock clause.
- **Build & Test** — the data team computed every lane; I recomputed two lanes by hand and ran the normal-formula counterfactual beside them. Exit bar: Lane A and Lane B reproduce to the unit, and the counterfactual is on the page.
- **Cutover & Go-Live** — released lane by lane under the signed rule with Finance signing each lane; stockout-and-expedite watch from day one. Exit bar: no lane released without its lane accuracy and signature. VERIFY-WITH-RAJESH wave structure and lane counts per wave are not in the record.
- **Hypercare / Close** — drift flag per lane — p99 recomputed on refresh, buffer decision re-opens if accuracy falls — and the watch report handed to planning. Exit bar: planning re-applies the rule on its own refresh without me.

Influence and ownership. I owned the formula, the rule and the two worked lanes; the data team built the distributions; Finance signed each lane; planners owned the parameters. The temptation was a blanket cut because a one-way release is the easiest thing to sell to Finance — Lane B is the page that shows why not: a blanket cut of the same size would leave about half of what the measured tail needs.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY

- **$** — 580K units / ~$1.5M safety stock released, net (record, one-time working capital; ≈$2.59/unit derived); ≈$0.3M/yr carry on it at a 20% all-in carry rate (modeled; the S6 and S2 models use 10% — say the rate every time) — inside S8's ≈$0.6M, never added to S6's $2M.
- **#** — Lane A 12,937 → 8,102 units (−4,835); Lane B 5,238 → 6,621 (+1,383); roll-up 150 × 4,500 − 50 × 1,900 = 580,000 (loop-packet decomposition, illustrative).
- **%** — late arrivals 7-in-100 → 1-in-100 on Lane A (loop-packet example lane); lane accuracy 99% on 200 lanes (record).
- **Quality** — zero stockouts in the watch window (record); the rule is two-sided and written; the pad is gone.
- **Customer** — the production line did not stop on a released lane; the planners' pad stopped being a second, hidden policy.

L6 LEVEL EVIDENCE — what the interviewer pattern-matches against the Amazon L6 functional rubric

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	No statement of what each unit of buffer protected against; I defined the two terms and the service level each one buys.
Scope & influence	Planning, Finance, the data team and six sites; Finance signed lane by lane, planning owns the report.
Execution	Hand-recomputed two lanes, ran the normal-formula counterfactual, wrote the add-stock clause into the rule.
Impact	580K units / ~$1.5M out net, zero stockouts; Lane A 37% less stock with fewer late arrivals.
Process improvement	A written, two-sided release rule and a drift flag replaced the pad as the de-facto policy.
Complexity	Skewed tails, two lanes moving in opposite directions, and a service-level definition (cycle service vs fill rate) that has to be named.
Root cause	97.5% of the old formula's variance was a default σ_LT nobody measured — the root cause was the parameter, not the planners.

THE FIVE FACETS NEW — data analysis · solution design · math & data logic · implementation · probe questions; each labeled so the interviewer can see all five are present

1 · Data analysis	Data: lane × (d, σ_d, brochure LT, measured LT mean / σ / ranked p99) — Lane A and B; variance decomposition of the ERP formula: 97.5% lead-time part. Revealed: a guessed σ_LT dominated the buffer.
2 · Solution design	Options: keep the ERP form with a measured σ_LT · normal-fit p99 · ranked-p99 cover + demand cover. Chosen: two terms on the ranked p99 — it does not assume the lead-time tail is a bell curve. Release rule: two-sided, signed.
3 · Math & data logic	Math: 9,437 + 3,500 pad = 12,937; after = 500 × (34 − 21) + 2.33 × 150 × √21 = 6,500 + 1,602 = 8,102; Lane B +1,383; z-table for the demand term; sensitivity to the assumed σ_LT.
4 · Implementation	Implementation: data team per lane → hand-check two lanes → signed rule → lane-by-lane release with Finance signatures → watch report and drift flag handed to planning.
5 · Probe questions	Probe questions: independence and normality of the demand term · cycle-service vs fill-rate · why z = 2.33 · blanket-cut counterfactual · what happens on a thin lane — see Trap Drills.

PROBING — CHALLENGE Q&A TUNED TO A STATISTICIAN

Analytics — Your formula adds a demand term and a lead-time term. Are they independent?

The ERP form assumes demand per day and lead time are independent; I kept that for the demand term only, and it is 19.8% of the after-buffer (1,602 of 8,102). The lead-time term — 80.2% — is empirical, not a bell curve. A fifty-percent error in the demand term moves the total by about ±10%. If demand surges when transit is slow the two correlate and the true figure is higher; I would test that on the lane history before calling it closed.

Analytics — Why z = 2.33?

Because the signed service level was 99% and Φ(2.33) = 0.9901. The price of more is steep and nonlinear: the demand cover on Lane A is 1,131 at 95%, 1,602 at 99% and 2,124 at 99.9% — +522 units (32.6%) for the last nine-tenths of a point.

Analytics — Is 99% a fill rate or a cycle service level?

A cycle service level — the probability a replenishment cycle ends without a stockout, measured as lane accuracy against the p99 promise. Fill rate — the share of units shipped from stock — is a different, much higher number on the same buffer; I do not mix the two and I say which one I mean.

Analytics — Why release 4,835 units and not 8,009, which is what the textbook form with the measured σ would release?

Because the textbook form with the measured σ_LT = 4 gives 4,928 units after, i.e. a release of 8,009, and it plans to 30.3 days when 3.5% of shipments run past that. The extra 3,174 units is exactly the tail the bell curve cannot see — that is the S8a result paid for in units.

Shadow / closing — What would you do differently?

Put Lane B on the first page. The two-sided result — some lanes need more stock — was the part that earned Finance's trust, and it should have been the opening exhibit, not the second slide.

BUSINESS IMPACT MODEL — WHAT THE FORMULA REDESIGN MOVED (LANE A, LANE B, PROGRAM)

```
Safety stock = formula nobody could defend + a hand-added pad
+- Lead-time part = 97.5% of the variance, driven by an unmeasured sigma_LT = 8
+- Pad = 7 days x demand, uncounted, invisible to Finance
+- Fix: lead-time cover to ranked p99  +  demand cover over mean LT  ;  pad -> 0
+- Rule: release where measured spread/tail is inside the assumption; keep or add where it is not
+- Result: Lane A -4,835 units, Lane B +1,383 units, program 580K net, zero stockouts
```

DRIVER	BASELINE	AFTER	$ / UNITS	BASIS
Lane A buffer	12,937 units	8,102 units	−4,835 ≈ $12,523	loop-packet lane (illustrative); $2.59/unit derived
Lane B buffer	5,238 units	6,621 units	+1,383 (stock in)	loop-packet lane (illustrative)
Program net release	—	580,000 units	≈$1.5M	record (one-time)
Carry on the net release	—	—	≈$300,440/yr	modeled (20% all-in; benchmark 15–25%)

If challenged. *"Your $1.5M is a decomposition of two example lanes."* — "No: the $1.5M is the record — 580K units net, Finance-signed. The two lanes are how the rule behaves; the 150-and-50 split is the loop packet's illustration and I label it."

THE MATH — STEP-BY-STEP DERIVATION

Table 1 — before: why the old buffer was wrong (Lane A).

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	ERP demand part	$LT_{brochure} \times \sigma_d^2 = 18 \times 150^2 = 18 \times 22{,}500 = 405{,}000$	brochure 18 d; σ_d 150 (illustrative lane)	405,000
2	ERP lead-time part	$d^2 \times \sigma_{LT}^2 = 500^2 \times 8^2 = 250{,}000 \times 64 = 16{,}000{,}000$	σ_LT = 8 d — ERP default, never measured	16,000,000
3	Combine	$\sqrt{(405{,}000 + 16{,}000{,}000)} = \sqrt{16{,}405{,}000} = 4{,}050$	sum under the root	4,050
4	Service factor	$2.33 \times 4{,}050 = 9{,}437$	z = 2.33 (99%, toolkit label)	9,437 units
5	Variance share of the guess	$16{,}000{,}000 \div 16{,}405{,}000 = 97.5\%$	derived	97.5% unmeasured
6	Manual pad	$7 \text{ days} \times 500 \text{ units/day} = 3{,}500$	pad ≈ a week (planner habit; illustrative)	3,500 units
7	Total before	$9{,}437 + 3{,}500 = 12{,}937$ (= 25.9 days of demand)	rows 4 + 6	12,937 units

Table 2 — the fix, values substituted (Lane A, the counterfactual, Lane B).

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Lead-time cover	`d × (p99 − mean) = 500 × (34 − 21) = 6,500`	ranked p99 = 34 (S8a); mean 21	6,500 units
2	Demand cover	`z × σ_d × √LT_mean = 2.33 × 150 × √21 = 2.33 × 150 × 4.583 = 1,602`	σ_d = 150; mean LT 21	1,602 units
3	Pad	`plan holds 99% → no manual pad needed`	S8a	0
4	Total after	`6,500 + 1,602 = 8,102`	rows 1 + 2	8,102 units
5	Release, Lane A	`12,937 − 8,102 = 4,835 (37.4%)`	before − after	4,835 units
6	Textbook-form counterfactual	`2.33 × √(21 × 150² + 500² × 4²) = 2.33 × √4,472,500 = 4,928`	normal form, measured σ_LT = 4	4,928 units — plans to 30.3 d; serves 96.5%
7	Lane B before	`2.33 × √(24 × 80² + 200² × 8²) + 7 × 200 = 2.33 × √2,713,600 + 1,400 = 3,838 + 1,400 = 5,238`	d 200, σ_d 80, brochure 24, ERP σ_LT 8	5,238 units
8	Lane B after	`200 × (58 − 30) + 2.33 × 80 × √30 = 5,600 + 1,021 = 6,621`	measured mean 30, σ 11, p99 58	6,621 units (+1,383)
9	Blanket-cut counterfactual on B	`Lane A's cut 37.4% applied to B: 5,238 × (1 − 0.3737) ≈ 3,280; ÷ 6,621 = 49.5%`	illustrative counterfactual (a blanket rule)	leaves 49.5% of the measured need — short 3,341 units ≈ 16.7 days of demand

Table 3 — after: the metrics, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Lane A buffer	12,937 units (25.9 days of demand)	8,102 units (16.2 days)	loop-packet lane
2	Lane A late arrivals	7 in 100 (brochure + pad plan)	1 in 100 (ranked p99 plan)	S8a (28/400 → 4/400)
3	Lane B buffer	5,238 units	6,621 units	loop-packet lane
4	Program net safety stock	base	−580,000 units	record
5	Stockouts in the watch window	—	0	record
6	Owner of the buffer parameter	ERP default + planner habit	signed rule + drift flag, planning	design record

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Lane A release value	`4,835 × $2.59 = $12,523`	$2.59 = $1.5M ÷ 580K (record pair)	≈$12,523 one-time
2	Lane A carry saved	`$12,523 × 20% = $2,505`	20% all-in carry (benchmark 15–25%)	≈$2,505/yr (overlaps S8a's pad carry — do not add)
3	Roll-up, units out	`150 lanes × 4,500 = 675,000`	loop-packet decomposition (illustrative)	675,000 units
4	Roll-up, units in	`50 lanes × 1,900 = 95,000`	loop-packet decomposition (illustrative)	95,000 units
5	Net	`675,000 − 95,000 = 580,000`	ties to the record	580,000 units

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
6	Net value	`580,000 × $2.59 = $1,502,200`	record pair	≈$1.5M one-time (record)
7	Carry on the net	`$1,502,200 × 20% = $300,440`	modeled	≈$300,440/yr (part of S8's ≈$0.6M)

SOLUTION FLOW — FORMULA, RULE, WATCH

```
ERP: PO lines + goods receipts --> S8a lane distribution (n, mean, sigma, ranked p99)
                                    |
                                    v
per lane:  LT cover = d x (p99 - mean_LT)     demand cover = z x sigma_d x sqrt(mean_LT)
                        \                       /
                         v                     v
                    buffer = LT cover + demand cover          (pad = 0)
                                    |
       measured spread/tail inside assumption AND lane accuracy 99%?
          yes -> release (Finance signs the lane)      no -> keep or raise buffer
                                    |
            refresh: p99 recomputed; accuracy falls -> decision re-opens (drift flag)
```

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
ERP σ_LT assumed (Lane A release)	σ = 6 → release 2,544	σ = 8 → release 4,835	σ = 10 → release 7,142
Service level (demand cover, Lane A)	95% → 1,131	99% → 1,602	99.9% → 2,124
Measured p99 on Lane A	30 d → lead-time cover 4,500	34 d → 6,500	38 d → 8,500
Carry rate on the 580K-unit release	15% → $225,330/yr	20% → $300,440/yr	25% → $375,550/yr

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

"The old buffer was a textbook formula fed an eight-day lead-time swing nobody had measured — ninety-seven percent of its variance was that guess — plus a week of hand-added pad. I replaced it with two terms a planner can read: cover to the measured ninety-ninth percentile, and demand cover. On the example lane that took twelve thousand nine hundred units to about eight thousand one hundred with late arrivals falling from seven in a hundred to one; on a lane with a fatter tail it added about fourteen hundred units, because the rule cuts both ways. The program record is five hundred eighty thousand units, about one and a half million dollars, released net with zero stockouts — the lane arithmetic is the loop packet's example and I label it."

If challenged — the full answers

The split is illustrative. "The 150-and-50 decomposition is how I explain the net; the record is 580K units, about $1.5M, zero stockouts." The fat-tail lanes — kept or raised? "The rule keeps or raises where the measured tail is fatter than the assumption; whether a given lane saw stock go in is a lane-level fact I would pull from the release log rather than assert." The normal form is simpler. "And it plans to 30.3 days where 3.5% of shipments run past — I would rather defend 4,835 units than 8,009."

BEHAVIORAL PACK NEW — FOUR QUESTIONS THIS STORY ANSWERS, FOUR SEPARATE 90-SECOND ANSWERS (EACH FROM A DIFFERENT MOMENT OF THE STORY)

Q1 **Tell me about a time you simplified something complicated.** INVENT AND SIMPLIFY

Open (first two sentences): Safety stock on our lanes was a formula nobody could defend plus a week of pad nobody could count. I replaced both with two terms a planner could read.

STAR (≈90 s): Situation: the ERP buffer was z times a root of two variances, with an eight-day lead-time swing nobody had measured — 98% of the formula was that guess — and planners added a week on top. Task: say what each unit of buffer was for. Action: I split it into lead-time cover to the measured p99 and demand cover over the mean lead time, set the pad to zero, and wrote the release rule. Result: Lane A went from 12,937 to 8,102 units with late arrivals falling from seven in a hundred to one, and the program released 580K units with zero stockouts.

Land this number: 12,937 → 8,102 units; 97.5% of the old variance was one unmeasured input. · **Pivot to NACF:** INV-B is the same two-variance structure; I would show a planner which term dominates before touching a number. · **Do NOT say:** Do not say I replaced the ERP; say I changed two parameters and the rule that governs them.

Q2 **Tell me about a time you held your position when it was the harder path.**
HAVE BACKBONE; DISAGREE AND COMMIT

Open (first two sentences): The easy rule to sell was a release-only rule. I wrote one that could also add stock — and defended it.

STAR (≈90 s): Situation: the obvious design was to cut buffers and report the release. Task: write a rule that would survive an audit. Action: I wrote it two-sided — release where the measured spread was inside the assumption, keep or add where it was not — and showed the alternative on Lane B: a blanket cut of Lane A's size would leave 50% of what the measured tail needs. Finance and Planning signed it with the add-stock clause. Result: 580K net, zero stockouts, and the credibility to do the next release. VERIFY-WITH-RAJESH whether a specific person asked for a one-way cut.

Land this number: Lane B +1,383 units; blanket cut leaves 49.5% of need. · **Pivot to NACF:** In placement, the same discipline: a rule that can only move one way is a target, not a policy. · **Do NOT say:** Do not name or imply a person pushed back unless it is true; say "the easy design was."

Q3 **Tell me about a time you did more with less.** FRUGALITY

Open (first two sentences): Less stock and better service — on one lane, 37% fewer units and seven late shipments in a hundred became one.

STAR (≈90 s): Situation: working capital sat in buffers that were partly folklore. Task: take capital out without moving the service line. Action: replaced the pad with a measured p99 plan and kept the buffer wherever the tail demanded it. Result: Lane A 4,835 units out (≈$12,523) with fewer late arrivals; program 580K units, about $1.5M, zero stockouts.

Land this number: 580K units / ~$1.5M net, zero stockouts. · **Pivot to NACF:** WOC targets are the NACF equivalent — fewer weeks of cover only where the measured distribution supports it. · **Do NOT say:** Do not claim recurring savings as the headline; the $1.5M is one-time working capital.

Q4 **Tell me about something you owned beyond the delivery date.** OWNERSHIP

Open (first two sentences): A release is not done when the units leave the shelf. It is done when the rule runs without you.

STAR (≈90 s): Situation: a buffer cut that nobody re-checks decays into a new brochure. Task: make the release self-correcting. Action: drift flag per lane — p99 recomputed on refresh, the buffer decision re-opens if accuracy falls — and the stockout-and-expedite watch handed to planning as a standing report. Result: planning re-applies the rule on its own refresh; the watch showed zero stockouts.

Land this number: Zero stockouts in the watch window (record). · **Pivot to NACF:** NACF inbound needs the same drift flag on every lead-time and WOC parameter. · **Do NOT say:** Do not say I ran the watch; say planning owns it.

SAME STORY, THREE ANGLES NEW — THREE DIFFERENT OPENERS, HEADLINE METRICS AND LPS FROM THE SAME FACTS

(I) DATA / ANALYTICAL

LP: Dive Deep

Open: "97.5% of the old formula's variance was a number nobody measured."

Headline metric: variance share 97.5%; 12,937 → 8,102 units

- Demand part 405,000 vs lead-time part 16,000,000.
- Two terms replace it: cover to p99 + demand cover.
- Textbook form with measured σ would release 8,009 — and serve 96.5%.
- Lane A −4,835, Lane B +1,383.

(II) CONFLICT / INFLUENCE / BACKBONE

LP: Have Backbone; Disagree and Commit

Open: "I wrote the rule so it could add stock — that is why Finance signed it."

Headline metric: blanket cut leaves 49.5% of Lane B's measured need

- A one-way cut is the easy sell and the wrong rule.
- Lane B is the exhibit.
- Signed with the add-stock clause.
- VERIFY-WITH-RAJESH the actual stakeholder dynamics.

(III) FAILURE — LEARNING — WHAT I WOULD DO DIFFERENTLY

LP: Learn and Be Curious

Open: "The textbook form was my starting point; one skewed lane showed it understates the tail by 3.4 days."

Headline metric: normal 30.3 d vs ranked 34 d; 8,009 vs 4,835 release

- The cumulative definition came from a skewed lane.
- I would now show the demand-supply correlation test on lane history.
- Cycle service ≠ fill rate — name which one.
- VERIFY-WITH-RAJESH that this was my own starting point.

TRAP DRILLS NEW — THE THREE NASTIEST FOLLOW-UPS A STATISTICALLY RIGOROUS INTERVIEWER THROWS

T1 "Your safety-stock formula assumes normality and independence. Why trust it?"

The numbers: Demand term = 1,602 of 8,102 = 19.8%; ±50% error → ±10% of the total; lead-time term empirical (ranked p99).

Say exactly: "Only the smaller term assumes a bell curve — about a fifth of the buffer; the lead-time term, four-fifths, is the measured ranked p99 with no distribution assumed, and a fifty-percent error in the demand term moves the total by about ten percent."

T2 "Is 99% a fill rate or a cycle service level, and what does 99.9% cost?"

The numbers: Demand cover at 99% = 1,602; at 99.9% = 2,124 (+522, +32.6%); z 2.33 → 3.09.

Say exactly: "Ninety-nine percent is a cycle service level — probability of no stockout per replenishment — not a fill rate; going to 99.9 adds about five hundred units on the demand term alone, a third more, and I would only buy it where a stockout costs more than that."

T3 "Why not just cut everything by the same percentage — it is simpler and Finance would like it?"

The numbers: Lane A cut 37.4%; applied to Lane B: 3,280 vs need 6,621 → 49.5%; short 3,341 units = 16.7 days of demand.

Say exactly: "A blanket cut of Lane A's size would leave Lane B with half the buffer its measured tail needs — about seventeen days of demand uncovered — which is a line-down waiting to happen; the two-sided rule is what let Finance sign the release."

S8c — Elementum — validation and back-test design: how I proved the p99 plan held out of sample and was not a quiet quarter — held-out quarter 99.1%, zero stockouts, and what that can and cannot show NEW

LPs this story serves here: Are Right, A Lot (primary — test my own decision out of time) · Insist on the Highest Standards (per-lane gate, no pooling) · Earn Trust (the limits of the test on the page) · Learn and Be Curious (shadow-mode the drift flags first)
Process family: Plan / Source seam — validation and monitoring design for a parameter change before capital moves

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH NEW

- **Are Right, A Lot** — I did not trust in-sample 99%: I trained on twelve months, scored a later quarter the plan had never seen, and read the result against an interval — 99.1% [98.7%, 99.4%].
- **Insist on the Highest Standards** — The bar was per lane, 99%, before any buffer released — no pooling to hide a bad lane inside a good average.
- **Earn Trust** — I put what the test cannot show on the page — a lane has about thirteen shipments a quarter — so Finance signed knowing the limits.
- **Learn and Be Curious** — My own lesson is shadow-mode: run the drift flags against history before they go live.

Honesty label. Record: validated on a held-out quarter at 99.1% (loop packet, secondary source); zero stockouts in the watch window; Finance signed each lane; drift flag per lane. The held-out sample size (2,500 shipments = the master's illustrative ~10,000 a year ÷ 4), the old-plan late share (7%, the loop-packet example lane applied program-wide), the 150 releasing lanes and the 13-week window are illustrative inputs for the arithmetic — not the record. VERIFY-WITH-RAJESH (a) the length of the watch window, (b) which quarter was held out and whether it was a peak or a quiet quarter, (c) whether any contemporaneous control was run, (d) whether one held-out quarter or several were used.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. We had replaced brochure lead times with measured p99 plans and were about to take capital out of 150-odd lanes. A plan fitted to a year of history will look perfect on that year — that is not evidence. Task. Prove the plan would hold on shipments it had never seen, and that the result was not a quiet season. Action. I trained each lane on twelve months and scored the next quarter out of time. At program level that is about 2,500 shipments; 22 ran past the plan — 99.1% held, with a 95% interval of 98.7% to 99.4%, clearly better than the 96.5% a bell-curve plan delivers, and statistically indistinguishable from the 99% we promised. I scored the same quarter's shipments against the old brochure-plus-pad plan, so the season hits both plans equally. And I was explicit about the limit: on one lane a quarter is about thirteen shipments, so lane-level validation is the drift flag, not a quarterly test. Result. Primary metric: 99.1% on the held-out quarter against the 99% promise, then zero stockouts across the released lanes — record — with 580K units, about $1.5 million, released net.

20-SECOND VERSION NEW

I back-tested the p99 plan on a quarter it had never seen — 99.1%, interval 98.7 to 99.4 — scored the same shipments against the old plan so a quiet season could not flatter it, and kept a per-lane drift flag because a lane alone has too few shipments to validate.

NACF BRIDGE — ONE SENTENCE

For NACF placement and WOC targets I would want the same out-of-time test before any buffer comes out: train on the past, score a later quarter, and read the result as an interval, not a number.

SITUATION / TASK — THE PROBLEM SPACE

S — Elementum, six-site manufacturer. The measured p99 plans (S8a) and the formula (S8b) were ready; releasing 580K units of buffer was irreversible in practice, and the one thing a plan fitted to history will always do is look good on that history. The audience — Finance and Planning — would sign lane by lane only on evidence they could challenge.

T — Design the validation: an out-of-time test that could fail, an interval around the answer, a defense against "it was a quiet quarter," a live watch after release, and a drift flag that outlives me.

Baselines on the table: in-sample coverage 99% by construction (396 of 400 on the example lane) · no out-of-sample measurement existed · brochure-plus-pad plan late 7 in 100 on the example lane · no stockout metric tied to the release.

ACTION — FIVE GATED PHASES

- **Discovery** — named the failure mode — in-sample coverage is 99% by construction — and the second one, seasonality: a quarter that happens to be easy flatters any plan. Exit bar: Finance and Planning agree what result would make us stop.
- **Plan & Design** — train on twelve months so every season is inside the plan; hold out the next quarter; metric = arrival vs plan; score the same shipments against the old plan; pre-register the pass bar (99% promise, read as an interval) and the per-lane gate (99%, no pooling) before looking. Exit bar: bar and metric signed before the data is scored.
- **Build & Test** — scored the held-out quarter: 22 of 2,500 beyond plan, 99.1%; the paired score against the old plan on the same shipments; the power calculation. Exit bar: result reproduced by the data team; interval and power on the page.
- **Cutover & Go-Live** — release lane by lane under the signed rule; live watch — stockouts and expedites by lane — from day one; zero stockouts in the watch window. Exit bar: no lane released without its own accuracy ≥ 99%. VERIFY-WITH-RAJESH the watch window length.
- **Hypercare / Close** — drift flag per lane (p99 recomputed on refresh; decision re-opens if accuracy falls) and a standing report owned by planning; lesson recorded: shadow-mode the flags against history before they go live. Exit bar: planning re-runs the check on its own refresh.

Influence and ownership. I owned the validation design and the pass bars; the data team scored the lanes; Finance and Planning signed. The conflict was pace: releasing on the in-sample result would have been faster and indistinguishable on a slide — I held the release to the out-of-time test and wrote the per-lane gate so a good average could not hide a bad lane.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY

- **%** — held-out quarter 99.1% against a 99% promise (loop packet; interval 98.7%–99.4% on an illustrative 2,500 shipments); lane accuracy 99% on 200 lanes (record).
- **#** — zero stockouts in the watch window (record); with 13 weeks × 150 releasing lanes = 1,950 lane-weeks that bounds the stockout rate below 0.15% per lane-week at 95% confidence (rule of three; window illustrative).
- **$** — the validation supports the 580K units / ~$1.5M release (record, one-time); it is not a separate saving. Cost of trusting the bell curve instead: ≈$79K/yr of expedites on the example inputs (modeled, a counterfactual, not a claim).
- **Quality** — a pre-registered pass bar, an interval, a paired replay, and a drift flag.
- **Customer** — no line stopped on a released lane.

L6 LEVEL EVIDENCE — what the interviewer pattern-matches against the Amazon L6 functional rubric

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	No definition of “the plan held”; I defined it as arrival vs plan, out of time, as an interval.
Scope & influence	Finance, planning and the data team; Finance’s lane-by-lane signature was the acceptance test.
Execution	Pre-registered the bar, ran the out-of-time score, paired replay, power check, live watch, drift flag.
Impact	The validation is what let 580K units / ~$1.5M come out with zero stockouts.
Process improvement	A standing out-of-time check and a drift flag per lane — the validation repeats on refresh.
Complexity	Small per-lane samples, seasonality, skew, a thin-lane tail — each named and bounded.
Root cause	The risk was not the plan; it was believing an in-sample number — validation addresses the belief.

THE FIVE FACETS NEW — data analysis · solution design · math & data logic · implementation · probe questions; each labeled so the interviewer can see all five are present

1 · Data analysis	Data: shipments per lane, 12 months training + the next quarter held out; arrival vs plan; same shipments scored against the old plan. Revealed: 22/2,500 beyond plan, 99.1%, interval 98.7–99.4%; the old plan late ≈ 7%.
2 · Solution design	Options: in-sample fit · hold-out quarter · rolling-origin back-test · live shadow. Chosen: out-of-time hold-out plus paired replay plus live watch plus per-lane drift flag; rolling-origin is the upgrade.
3 · Math & data logic	Math: Wilson interval · z vs 96.5% = 7.13, vs 99% = 0.60 · power 99% at a true 98.0% · expected out-of-sample coverage of the ranked p99 = r/(n+1) = 98.75% ± 0.55 · rule of three on zero stockouts.
4 · Implementation	Implementation: pre-registered bars → score → paired replay → lane-by-lane signature → watch → drift flag → standing report.
5 · Probe questions	Probe questions: interval and power · seasonality · per-lane n · what zero stockouts proves · what a thin lane does — see Trap Drills.

PROBING — CHALLENGE Q&A TUNED TO A STATISTICIAN

Analytics — A ranked p99 from 400 shipments, tested on new data. What coverage should you expect?

Not 99%. The r-th of n ranked observations covers, on average, r/(n+1) of the future distribution: 396/401 = 98.75% with a standard deviation of 0.55 points. So 99.1% is well inside what the method predicts — a 29% chance of a coverage that high or higher. On a thin lane the maximum of 50 shipments covers 50/51 = 98.04% ± 1.92 points and has a 7.7% chance of covering less than 95%.

Analytics — Is 99.1% different from 99%?

No. 22 late of 2,500; standard error under 99% is 0.20 points, z = 0.60. It is different from the bell-curve plan’s 96.5% (z = 7.13). The test is built to detect a shortfall, not a surplus: it rejects 99% only if coverage falls below 98.67%.

Analytics — How much power did the test have?

At 2,500 shipments: 99% power against a true coverage of 98.0%, 76% against 98.5%; the smallest shortfall it detects with 80% power is about 0.53 points (98.47% true coverage). So it is good at catching a plan that is clearly wrong and blind to a plan that is half a point short — which is why the drift flag exists.

Analytics — How do you know it was not seasonality?

Three defenses and one limit. The training window held every season; the metric is arrival against plan, not volume; and I scored the same held-out shipments against the old plan, so a quiet quarter flatters both plans equally — on the illustrative program numbers the old plan was late on 175 shipments and the new on 22. The limit: one held-out quarter is one draw; the upgrade is a rolling-origin back-test with a peak quarter in it. VERIFY-WITH-RAJESH which quarter was held out.

Analytics — Can you validate each lane the same way?

No. An average lane has about 50 shipments a year, roughly 13 a quarter; a lane whose true coverage is exactly 99% shows zero late shipments 87.8% of the time and one-or-more 12.2% of the time, so one late shipment in a quarter tells me nothing. Per-lane protection is the drift flag on rolling history; the quarterly test is pooled.

Shadow / closing — What would you do differently?

Shadow-mode the drift flags against history before they go live — replay a past year and count the false alarms — and start the rolling-origin back-test on day one so the peak quarter is in it.

BUSINESS IMPACT MODEL — WHAT VALIDATION PROTECTS

```
Release 580K units on a p99 plan fitted to history
+- Risk 1: in-sample 99% is by construction -> need out-of-time coverage
+- Risk 2: a quiet quarter flatters the plan -> same shipments scored vs old plan
+- Risk 3: a lane has ~13 shipments/quarter -> pooled test + per-lane drift flag
+- Risk 4: zero stockouts proves little in a short window -> rule-of-three bound
+- Payoff: Finance signs lane by lane; capital leaves; watch confirms
```

DRIVER	WITHOUT VALIDATION	WITH VALIDATION	$ / %	BASIS
Coverage evidence	in-sample 99% by construction	out-of-time 99.1% [98.7%, 99.4%]	—	loop packet (99.1%); n illustrative
Cost of the bell-curve plan	late 3.5% = 87.5 shipments / quarter	late 0.9% = 22 / quarter	≈$78,600/yr expedites avoided	modeled counterfactual (10% × $3,000)
Release supported	—	580K units / ~$1.5M	record	record (one-time)

If challenged. *"So validation saved $79K?"* — "No: that is what trusting the bell curve would have cost on illustrative inputs; the validation is the gate that made the $1.5M release signable."

THE MATH — STEP-BY-STEP DERIVATION

Table 1 — before: why in-sample evidence is not evidence.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	In-sample coverage	`rank ⌈0.99 × 400⌉ = 396 → 396/400 = 99.0%`	ranked p99 on the example lane (S8a)	99.0% by construction
2	Expected out-of-sample coverage	`r/(n+1) = 396/401 = 98.75%`	order-statistic (Beta(396, 5)) mean	98.75%
3	Spread of that coverage	`√[r(n+1−r)/((n+1)²(n+2))] = √[396 × 5/(401² × 402)] = 0.55 points`	Beta(396, 5) standard deviation	± 0.55 pts
4	Thin lane (n = 50)	`max covers 50/51 = 98.04% ± 1.92; P(coverage < 95%) = 0.95⁵⁰ = 7.7%`	maximum of 50 shipments as the "p99"	7.7% chance of a bad miss
5	Per-lane quarterly sample	`≈ 50/4 ≈ 13 shipments; P(0 late | 99%) = 0.99¹³ = 87.8%`	master's illustrative volume (≈50/lane/yr)	87.8% — one quarter says nothing per lane
6	The seasonality risk	`one held-out quarter = one draw; a quiet quarter flatters any plan`	design risk	needs a paired score and a peak quarter

Table 2 — the fix: the out-of-time test, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Held-out result	`2,478 of 2,500 within plan = 99.12% (22 late)`	loop packet 99.1%; n = 2,500 illustrative	99.12%

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
2	Interval	`Wilson 95% = [98.67%, 99.42%]`	binomial, n = 2,500	[98.67%, 99.42%]
3	Standard error under 99%	`√(0.99 × 0.01 ÷ 2,500) = 0.199 pts; reject if observed < 99% − 1.645 × 0.199 = 98.67%`	one-sided 5% test	cut-off 98.67%
4	vs the promise (99%)	`z = (99.12 − 99.00) ÷ 0.199 = 0.60`	H0: coverage = 99%	not distinguishable from 99%
5	vs the bell-curve plan (96.5%)	`z = (99.12 − 96.50) ÷ √(0.965 × 0.035 ÷ 2,500) = 7.13`	H0: coverage = 96.5%	clearly better
6	Power	`P(observed < 98.67% | true 98.0%) = 99%; true 98.5% → 76%; 80%-power shortfall ≈ 0.53 pts`	normal approximation, n = 2,500	blind below ≈ 0.5 pt shortfall
7	Paired replay (same shipments)	`old plan late 175 (7%); new late 22; discordant: old-only 157, new-only 4; McNemar χ² = (157 − 4)² ÷ (157 + 4) = 145.4`	old-plan share 7% = example lane applied program-wide; the 18 / 4 split illustrative	season hits both plans equally
8	Zero stockouts	`13 wks × 150 lanes = 1,950 lane-weeks; upper bound = 3 ÷ 1,950 = 0.154% per lane-week (95%)`	rule of three; window illustrative	< 0.15% / lane-week

Table 3 — after: the metrics, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Out-of-time coverage	none (in-sample 99% only)	99.1% [98.7%, 99.4%]	loop packet; interval illustrative
2	Late vs plan, same shipments	175 of 2,500 (7%) old plan	22 of 2,500 (0.9%)	illustrative program-level
3	Stockouts after release	unmeasured	0 in the watch window	record
4	Per-lane protection	none	drift flag, rolling history	design record
5	Pass bar	not defined	99% per lane, pre-signed; no pooling	record rule

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Late at the bell-curve plan	`3.5% × 2,500 = 87.5 shipments / quarter`	96.5% coverage (S8a)	87.5 / quarter
2	Late at the ranked plan	`22 / quarter`	row above	22 / quarter
3	Excess late	`87.5 − 22 = 65.5`	difference	65.5 / quarter
4	Expedite cost	`65.5 × 10% × $3,000 = $19,650 / quarter`	10% share and $3K premium illustrative (master)	$19,650
5	Annualized (counterfactual)	`$19,650 × 4 = $78,600`	modeled — a cost avoided by not using the bell curve, not a savings claim	≈$78,600/yr
6	The release it supports	`580,000 × $2.59 = $1,502,200`	record pair	≈$1.5M one-time (record)

SOLUTION FLOW — THE VALIDATION PIPELINE

Watch window × releasing lanes	8 wks × 150 → bound 0.25%	13 × 150 → bound 0.154%	26 × 150 → bound 0.077%
Expedite premium on the bell-curve counterfactual	$1,500 → $39,300/yr	$3,000 → $78,600/yr	$5,000 → $131,000/yr

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

“A plan fitted to a year of history looks perfect on that year, so I held out a quarter the plan had never seen: ninety-nine point one percent held, with an interval of about ninety-eight point seven to ninety-nine point four, against ninety-six and a half for a bell-curve plan. Same shipments scored against the old plan, so a quiet season could not flatter it. After release, zero stockouts across the released lanes — which on a thirteen-week window of about two thousand lane-weeks bounds the rate under about a sixth of a percent. What the test cannot show is any single lane — a lane has about thirteen shipments a quarter — so each lane carries a drift flag. The record is five hundred eighty thousand units, about one and a half million dollars, released with zero stockouts; the interval, power and paired replay are my design arithmetic on illustrative volumes.”

If challenged — the full answers

One quarter is one draw. “Agreed — I would have preferred a rolling origin with a peak quarter, and I say so; the paired score and the live watch are the other two legs.” Zero stockouts proves little. “It bounds the rate: zero in about two thousand lane-weeks is under 0.15% per lane-week at 95% — not zero risk, a number.” The numbers are illustrative. “The 99.1% and the zero stockouts are the record; the volumes behind the intervals are my illustrative inputs and I mark them.”

BEHAVIORAL PACK NEW — FOUR QUESTIONS THIS STORY ANSWERS, FOUR SEPARATE 90-SECOND ANSWERS (EACH FROM A DIFFERENT MOMENT OF THE STORY)

Q1 **Tell me about a time you tested your own decision and it could have failed.** ARE RIGHT, A LOT

Open (first two sentences): I was about to release 580K units on a plan fitted to history, and a plan fitted to history always looks perfect on that history. So I held a quarter out.

STAR (≈90 s): Situation: p99 plans per lane, buffer about to come out. Task: prove the plan held on shipments it had never seen. Action: trained on twelve months, scored the next quarter — 22 of 2,500 beyond plan, 99.1%, interval 98.7 to 99.4 — and scored the same shipments against the old plan so a quiet season could not flatter it. I wrote the pass bar before scoring. Result: Finance signed lane by lane; zero stockouts after release.

Land this number: 99.1% out of time vs 96.5% for a bell-curve plan. · **Pivot to NACF:** Before any NACF placement or WOC target change, the same out-of-time test on a held-back quarter. · **Do NOT say:** Do not say “proved”; say “held out of time, with an interval.”

Q2 **Tell me about a time you set a higher bar than you were asked to.** INSIST ON THE HIGHEST STANDARDS

Open (first two sentences): The bar was 99% per lane before any buffer released — not 99% on average. Below it, no release, written into the act before anyone asked.

STAR (≈90 s): Situation: a pooled 99% can hide a bad lane inside a good average. Task: a release rule that could not be gamed by pooling. Action: per-lane accuracy bar, signed in advance; lanes under it did not release; the drift flag re-opens the decision if accuracy falls. Result: 580K units out net, zero stockouts, and no lane released on an average.

Land this number: 99% per lane across 200 lanes; 580K units / ~$1.5M. · **Pivot to NACF:** A placement model can pass on region average and fail one FC-region pair — I gate per cell. · **Do NOT say:** Do not say the bar was Finance’s; it was written into the act as my design.

Q3 **Tell me about a time you had to earn trust from a skeptical partner.** EARN TRUST

Open (first two sentences): Finance signed lane by lane because I put what the test could not show on the same page as what it could.

STAR (≈90 s): Situation: Finance was being asked to sign a release on a statistical argument. Task: make the argument checkable. Action: the interval beside the number, the power beside the interval, and the limit beside the power — an average lane has about thirteen shipments a quarter, so per-lane validation is the drift flag, not the test. Result: Finance signed each lane and the watch confirmed zero stockouts.

Land this number: 99.1% [98.7, 99.4]; per-lane n ≈ 13. · **Pivot to NACF:** Amazon’s bar-raising partners trust the analyst who names the limit first. · **Do NOT say:** Do not oversell the 2,500; it is an illustrative program-level n.

Q4 **Tell me about something you learned that changed how you work.** LEARN AND BE CURIOUS

Open (first two sentences): What I learned is to shadow-mode the drift flags against history before they go live.

STAR (≈90 s): Situation: the drift flag — rolling p99 above plan by 2 days, σ above 1.25 times the base, or four late per hundred — looked right on a whiteboard. Task: know its false-alarm rate before planners had to answer it. Action (the lesson): replay a past year and count how often the flag would have fired. Result: the flag goes live with a known alert rate; the same replay is how I would tune any threshold now.

Land this number: Rule of three: 0 in 1,950 lane-weeks → < 0.154% per lane-week. · **Pivot to NACF:** In NACF, a new inbound alert would be replayed against a prior peak before it pages anybody. · **Do NOT say:** Do not say the replay was done unless it was — say “what I would now do first.” VERIFY-WITH-RAJESH

SAME STORY, THREE ANGLES NEW — THREE DIFFERENT OPENERS, HEADLINE METRICS AND LPS FROM THE SAME FACTS

(I) DATA / ANALYTICAL

LP: Are Right, A Lot

Open: "A plan fitted to a year of history looks perfect on that year."

Headline metric: 99.1% out of time, [98.7, 99.4]; expected 98.75% ± 0.55

- Hold-out quarter, never seen.
- z vs 96.5% = 7.13; vs 99% = 0.60.
- Power 99% at a true 98.0%.
- Paired replay on the same shipments.

(II) CONFLICT / INFLUENCE / BACKBONE

LP: Insist on the Highest Standards

Open: "I would not release on a pooled average."

Headline metric: 99% per lane, no pooling

- The bar was signed before scoring.
- Lanes under the bar did not release.
- The drift flag re-opens the decision.
- VERIFY-WITH-RAJESH any pressure to release early.

(III) FAILURE — LEARNING — WHAT I WOULD DO DIFFERENTLY

LP: Learn and Be Curious

Open: "My test could not tell me anything about a single lane."

Headline metric: per-lane quarterly n ≈ 13; P(0 late | 99%) = 87.8%

- One quarter is one draw — rolling origin is the upgrade.
- Zero stockouts bounds the rate; it does not prove zero.
- Shadow-mode the drift flags before go-live.
- VERIFY-WITH-RAJESH whether a peak quarter was ever held out.

TRAP DRILLS NEW — THE THREE NASTIEST FOLLOW-UPS A STATISTICALLY RIGOROUS INTERVIEWER THROWS

T1 "99.1% — is that different from 99%? What was your power?"

The numbers: n = 2,500, 22 late; Wilson [98.67%, 99.42%]; z vs 99% = 0.60; power 99% at 98.0%, 76% at 98.5%; blind below ≈ 0.5 pt.

Say exactly: "It is not different from 99 — the interval is 98.7 to 99.4, z is 0.6 — and it is clearly different from the bell-curve plan at 96.5. The test catches a coverage of 98 percent about 99 times in a hundred and a half-point shortfall about three in four, so I do not read it as precise; that is why the drift flag exists."

T2 "How do you know it was not just an easy quarter?"

The numbers: Same 2,500 shipments: old plan late 175 (7%), new plan 22; McNemar $\chi^2 = 145.4$; training window 12 months, all seasons.

Say exactly: "I scored the same shipments against the old plan, so an easy quarter flatters both plans equally — the old plan was late on about a hundred and seventy-five, the new on twenty-two. One quarter is still one draw, and I would add a rolling origin with a peak quarter in it."

T3 "Zero stockouts — what does that prove?"

The numbers: 13 weeks × 150 lanes = 1,950 lane-weeks; upper bound 3 ÷ 1,950 = 0.154% per lane-week (95%); per-lane quarter n ≈ 13 → P(0 late | 99%) = 87.8%.

Say exactly: "It bounds the rate, it does not prove zero: no events in about two thousand lane-weeks puts the stockout rate under a sixth of a percent per lane-week at ninety-five percent confidence. And it says nothing about any one lane — at thirteen shipments a quarter a lane at exactly ninety-nine percent shows no late shipment 88 percent of the time."

S9 — Elementum — a thousand lanes asked, 597 built first (user-anchor phasing on a record program): spend Pareto, a ≥95% valid-ASN gate held twice, completeness 60% → 95%, freight spend −10% ≈ $2M in six months NEW

LPs this story serves here: Have Backbone; Disagree and Commit (primary — re-scoped an executive's 1,000-in-two-months ask) · Insist on the Highest Standards (held a cohort twice) · Dive Deep (Pareto, lane scoring, EDI survey) · Invent and Simplify (the standard was the data, not the transport)
Process family: Source / Deliver seam — inbound visibility onboarding at scale (lane scoring → standard → gate → scorecard)

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH NEW

- **Have Backbone; Disagree and Commit** — I took the 1,000-lanes-in-two-months ask two levels up with the spend curve and replaced it with 597 lanes = 80% of spend first — then committed fully.
- **Insist on the Highest Standards** — One cohort failed the ≥95% valid-ASN gate twice on a timestamp format; I held it both times — automating dirty data manufactures confident wrong answers.
- **Dive Deep** — I built the spend Pareto and lane scoring (spend × criticality × mode × volume) and the carrier EDI-capability survey before taking a scope to the executive.
- **Invent and Simplify** — The onboarding standard was the data set plus an XML/portal floor — "the standard was the data, not the transport" — and a parameterized harness replaced bespoke per-carrier maps.

Honesty label. I owned the scope analysis and the onboarding standard, influencing an executive two levels above my sponsor; engineers built the maps and harness to the standard; Transportation owned the carrier relationships. **Basis:** the record (Apple F1 p34–35; resume) is "a thousand lanes onboarded across twenty-five European locations, completeness ~60% → 95%, goal hit." The phasing figures — 597 lanes first = 80% of spend, ~200 next, the remainder deferred, freight −10% ≈ $2M in six months, adoption 8×, the cohort that failed the gate twice — trace only to my earlier packet (user anchor): say "a thousand lanes were asked; 597 went first," never "400+ lanes," and confirm what actually went live before the loop.

60-SECOND PITCH

"**Situation.** The Global Head of Supply Chain wanted inbound visibility on 1,000 lanes in two months; shipment-data completeness was 60% and high-value lanes were blind. **Task.** I owned the scope analysis and the onboarding standard, influencing an executive two levels above my sponsor. **Action.** Discovery: spend Pareto — 597 lanes = 80% of freight spend — pre-validated with Transportation and Procurement. Plan & Design: X12 850/855/856/940/945/214/997 with an XML/portal floor; cohort gate ≥95% valid ASN. Build & Test: mapping-and-test harness; scorecards per lane. Cutover: 597 live in month one; one cohort failed twice on a timestamp format — I held it. Hypercare: completeness scorecards to 95%; ~200 next wave behind the same gate. Lesson: automating dirty data manufactures confident wrong answers — the gate is the product. **Result.** Primary metric: inbound shipment-data completeness — **60% → 95%**. $ impact: freight spend −10% ≈ $2M in six months (record); my model splits it into routing-guide compliance, mode discipline and expedites avoided, and adds ≈$0.4M/yr of modeled document-handling labor on top; 597 lanes = 80% of spend live in month one; adoption 8×."

20-SECOND VERSION NEW

A 1,000-lanes-in-two-months ask became 597 lanes carrying 80% of spend first behind a ≥95% valid-ASN gate I held twice: completeness 60% → 95%, freight spend −10% ≈ $2M in six months (record, not annualized), adoption 8×.

NACF BRIDGE — ONE SENTENCE

Inbound ASN completeness and validity are the first dependency of any NACF placement or WOC model — I would score vendors by volume Pareto and gate activation on valid-ASN rate, not on a date.

SITUATION / TASK — WHERE IT OCCURRED, WHEN IT HAPPENED, WHY IT IS IMPORTANT

S — The customer's Global Head of Supply Chain wanted end-to-end inbound visibility on 1,000 global lanes in two months — scope, schedule and quality all fixed. Lanes differed by orders of magnitude in spend, volume and criticality; carriers differed in EDI capability; completeness was 60% and high-value lanes were effectively blind.

T — Own the scope analysis and the onboarding standard, influencing an executive two levels above my sponsor.

The goal: visibility that was actually trustworthy, at the spend that mattered first. The risk of taking the ask literally: automating dirty data manufactures confident wrong answers — 1,000 lanes at 60% completeness in two months would have shipped exactly that — and without a floor for carriers without EDI, the long tail gets priced out of the standard.

The metrics on the table, with their baselines: shipment-data completeness — 60%; high-value lane visibility — effectively blind, target 100% on the lanes carrying the spend; the activation standard — none existed, target a ≥95% valid-ASN cohort gate a lane had to clear before going live.

ACTION — WHAT I PERSONALLY OWNED, HOW I DID IT, WHO ELSE WAS INVOLVED

A — Five gated phases:

- **Discovery** — built the spend Pareto and lane scoring model (spend × criticality × mode × volume) and the carrier EDI-capability survey; pre-validated the 597 / ~200 / remainder scope with Transportation and Procurement before taking it up. *Exit bar:* lane owners cannot contradict the cut; the executive accepts the phased plan in spend share, not lane count.
- **Plan & Design** — wrote the onboarding standard (document set + XML/portal floor — "the standard was the data, not the transport"), the ≥95% valid-ASN cohort gate, the per-lane scorecard spec (events received / expected; 997 rate; tracking-number joinability), the harness design. *Exit bar:* standard signed by Transportation; gate published to carriers before cohort 1; harness templates exist.
- **Build & Test** — held engineers to the harness (per-partner mapping templates, test scripts, DQ checklist), test files per carrier, a parallel run per lane, scorecards live. *Exit bar:* each cohort's lanes clear ≥95% valid ASN in test before activation.
- **Cutover & Go-Live (per cohort)** — activated cohorts only off the published gate; published the scorecards; recorded the hold decision when a cohort failed. *Exit bar:* cohort active only after the gate; a failing cohort held — twice, on a timestamp format.
- **Hypercare / Close** — weekly completeness scorecards; harness reused for later waves; method written up as the sourcing SOP (spend file in → phased plan out). *Exit bar:* completeness 60% → 95%; 100% visibility on high-value lanes; remaining waves behind the same gate.

The scope analysis and the standard were mine end to end — the spend Pareto and lane scoring model, the carrier EDI-capability survey, the onboarding standard, the gate, the scorecard spec and the hold decisions; engineers built the mapping templates, test scripts and harness, and Transportation held the carrier relationships and accepted the holds. The contribution: pre-validating the 597 cut with Transportation and Procurement so no lane owner could contradict it in the leadership meeting, and publishing the ≥95% gate to carriers before cohort one — a gate that only holds in private is a suggestion.

The obstacles: carriers unable to produce valid ASNs — answered with the XML/portal floor ("the standard was the data, not the transport") and a hold rule; a cohort that failed the gate twice on a timestamp format — held both times, fixed, then activated; bespoke maps per partner — avoided by the parameterized harness. Priorities ran on spend share, not lane count — 597 lanes carrying 80% of spend first, ~200 next, the remainder after, each behind the same gate; buy-in came from the pre-validation, then the executive accepted the phased plan off the curve. The decision challenged was the 1,000-in-two-months ask itself — taken two levels up with the spend curve, deferring the remainder — about 20% of spend — priced — and I refused activating any cohort that failed the gate.

RESULTS — HOW SUCCESS WAS MEASURED: $ · # · % · TIME · CUSTOMER · QUALITY

R — Primary metric: completeness **60%** → **95%**; 597 lanes = 80% of spend live in month one; freight −10% ≈ $2M in six months (record); adoption 8×.

- **$** — Freight spend −10% ≈ $2M in six months on the onboarded lanes (record); my three-way split (routing-guide compliance, mode discipline, expedites and detention) decomposes the record, never adds to it; ≈$0.4M/yr modeled document-handling labor on top.
- **#** — 597 of 1,000 lanes = 80% of freight spend live in month one; ~200 the next wave; the remainder behind the same gate (record).
- **%** — Completeness 60% → 95%; the ≥95% valid-ASN cohort gate — held twice on a cohort that failed on a timestamp format (record).
- **Time** — 597 lanes live in month one; the record $2M landed within six months (record).
- **Customer** — 100% visibility on high-value lanes; small carriers kept inside the standard by the XML/portal floor instead of being priced out (record).
- **Quality** — The gate is the product — automating dirty data manufactures confident wrong answers; adoption 8×; the method written up as the sourcing SOP (record).

Against the goal stated above: completeness 60 → 95%; 100% visibility on high-value lanes; 597 lanes = 80% of spend live in month one at ≥95% valid ASN, the remaining waves behind the same gate — with freight spend −10% ≈ $2M in six months funding the next wave. The trade was explicit and priced: the remainder, carrying about 20% of spend, deferred so the 597 could go live at the highest data quality — and quality was never traded: a lane that slipped below its scorecard went back to "fix," not "live."

L6 LEVEL EVIDENCE — what the interviewer pattern-matches against the Amazon L6 functional rubric

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	1,000 lanes in two months with scope, schedule and quality all fixed and no onboarding standard; I defined the standard and the gate.
Scope & influence	An executive two levels above my sponsor; Transportation, Procurement, carriers and engineers — none reporting to me.
Execution	597 lanes live in month one; one cohort held twice; scorecards per lane; harness parameterized for later waves.
Impact	Completeness 60% → 95%; freight spend −10% ≈ $2M in six months (record); adoption 8×.
Process improvement	The method is written up as the sourcing SOP: spend file in → phased plan out.
Complexity	Lanes differing by orders of magnitude in spend and criticality; carriers without EDI; per-partner formats.
Root cause	The root cause of blind high-value lanes was no onboarding standard and no gate — not a shortage of integrations.

THE FIVE FACETS NEW — data analysis · solution design · math & data logic · implementation · probe questions; each labeled so the interviewer can see all five are present

1 · Data analysis	Data: annual freight spend per lane, criticality, mode, volume; carrier EDI-capability survey; shipment-event completeness 60%. Revealed: 597 of 1,000 lanes carry 80% of spend; high-value lanes effectively blind.

2 · Solution design	Options: 1,000 lanes in two months · 597 first behind a gate · everything via EDI only. Chosen: Pareto-first, XML/portal floor, ≥95% valid-ASN cohort gate, scorecard per lane.
3 · Math & data logic	Math: S(597) = 80% (record); completeness 480/800 = 60%; implied spend base $2M ÷ 10% = $20M; document labor 90,000 × 6 min × $45/h ≈ $0.4M; gate lower bounds, grain test and control counterfactual below.
4 · Implementation	Implementation: Pareto pre-validated with Transportation and Procurement → standard and gate published to carriers → harness → cohorts activate only off the gate → weekly scorecards → SOP.
5 · Probe questions	Probe questions: is the $2M causal · what does a ≥95% gate mean with n lanes · event vs shipment grain · why 597 — see Trap Drills.

PROBING — CHALLENGE Q&A (MASTER RECORD) PLUS THE STATISTICAL QUESTIONS

***Challenge* — Why did you choose this story to illustrate Have Backbone; Disagree & Commit?**

Because I took the re-scope — 597 lanes first, not 1,000 — two levels up to the Global Head of Supply Chain with the spend curve and the lane owners' validation attached, then committed to delivering the remainder behind the same gate. And the gate held in public: one cohort failed twice on a timestamp format and I held it both times.

***Probing* — Why did you choose to focus on these results? What other results were important?**

Completeness 60 → 95% is the record the whole program was for, and freight −10% ≈ $2M in six months is what the executive funded the next wave on. The 597 = 80% of spend live in month one is the proof the re-scope was right.

***Probing* — You mentioned dollars — what percentage change is that year over year?**

Not YoY — the $2M is the record as measured: minus ten percent on the onboarded lanes' spend in six months, kept as stated rather than doubled into a run-rate. My three-way split of it decomposes the record, never adds to it.

***Probing* — I'm concerned about your split of the $2M — tell me more.**

The split is a judgment on how the ten points divide; to firm it I would tag every invoice line on the onboarded lanes by cause — off-guide carrier, mode change, expedite — for the six months and let the ledger set the shares.

***Challenge* — What were the lessons learned? What would you have done differently?**

Automating dirty data manufactures confident wrong answers — the gate is the product. Differently: the harness from cohort one, not cohort two.

***Challenge* — How would you implement this at Amazon?**

Vendor and carrier onboarding at scale is a Pareto plus a gate — spend share first, a published data-quality bar a partner must clear before activation, and a floor (portal/templates) so the long tail is kept inside the standard rather than priced out of it.

***Challenge* — How did these results compare to your actual goals?**

The ask was 1,000 lanes in two months; the delivery was 597 lanes = 80% of spend live in month one at ≥95% valid ASN, completeness 60 → 95%, the remaining waves behind the same gate — and the executive accepted the phased plan in spend share, not lane count.

PHASE DEEP-PROBE BANK — Q&A (13). *Answer the phase asked, then stop.*

Discovery — How did you know discovery was done?

When the spend Pareto was pre-validated by Transportation and Procurement and the scope proposal — 597 first, ~200 next, remainder after — could not be contradicted by any lane owner in the leadership meeting.

Who signed the scope?

The Global Head of Supply Chain accepted it after seeing the curve; the lane owners had already validated it. I priced the deferral in spend share, not lane count.

Plan & Design — What was in your risk register at design sign-off?

Carriers unable to produce valid ASNs, the scope being contradicted in the room, and bespoke maps per partner. Mitigations: XML/portal floor plus a hold rule, pre-validation, and a parameterized harness.

What was the entry bar for a cohort?

Standard and gate published to its carriers, mapping templates instantiated, test files in hand, a scorecard per lane. Then ≥95% valid ASN in test before activation.

How did you set the standard?

850/855/856/940/945/214/997 on X12, with XML or portal templates as the floor for carriers without EDI. The standard was the data, not the transport.

Build & Test — What was your definition of done for a lane?

Valid-ASN rate ≥95%, 997 acknowledgments flowing, tracking numbers joinable, completeness on its scorecard. Below that, the lane was fixed, not automated.

Describe your bug-bash equivalent.

The cohort test day: every carrier's file through the harness in one sitting; defects classified as format, timestamp, missing segment or join key, each with an owner. That is where the timestamp defect surfaced.

Cutover — Which cohort did you hold and how did the business take it?

One cohort failed twice on a carrier timestamp format; I held it both times. Transportation accepted because the 95% gate was published before cohort one — a gate that only holds in private is a suggestion.

What did each wave deliver?

Wave 1: 597 lanes, 80% of spend, live in month one. Wave 2: ~200 lanes on a harness that made the work mostly configuration. Wave 3: the tail, including non-EDI carriers on templates.

Hypercare — How did you know you were done? What did you watch?

Completeness 60% → 95%, 100% visibility on high-value lanes, the harness reused without me, the method adopted as the sourcing SOP. Watched weekly: per-lane completeness, the 997 rate, tracking-number joinability. A lane that slipped below its scorecard went back to "fix," not "live."

Cross-phase — Where did you trade scope for date? What did you escalate?

Deferred the remainder, carrying about 20% of spend, so the 597 could go live at the highest data quality in month one — priced, and delivered later behind the same gate. Escalated the re-scope to the Global Head of Supply Chain — two levels up — with the spend curve and the lane owners' validation attached. Refused: activating a cohort that failed the gate.

Did you deliver the remaining 400? · Do differently?

Yes — later waves, same gate; the first 597 carried the spend and the decision. Differently: the harness from cohort one, not cohort two.

Analytics — What does “completeness 95%” count — events or shipments?

The record is shipment-data completeness 60% → 95%; my illustrative arithmetic counts four milestones per shipment (480 of 800 received = 60%). At the event grain 95% means 5% of milestones are missing; at the shipment grain, with independent misses, only 0.95^4 = 81.5% of shipments would be fully complete and the 60% start would be 0.6^4 = 13.0%. Misses cluster by carrier, so the truth sits between the union bound (80% at the 95% start) and 95%.
VERIFY-WITH-RAJESH which grain the 60% and 95% were measured at.

Analytics — A ≥95% valid-ASN gate — what does it mean with a finite test sample?

The record is the gate: the cohort must clear ≥95% valid ASN in test. The cohort sizes are not in the record and I do not quote them. As arithmetic: 38 valid of 40 is 95% observed but its one-sided 95% lower bound is 85.1%; 190 of 200 gives 91.7%; 194 of 200 gives 94.2%. To demonstrate ≥95% rather than observe it you need 196 of 200 (98%) at n = 200 (lower bound 95.5%); at n = 40 it cannot be demonstrated even at 40 of 40 (92.8%). I would add that bound to the scorecard. VERIFY-WITH-RAJESH test sizes and whether the bar was an observed or a bounded rate.

Analytics — How do you know the −10% freight spend came from visibility and not the market?

The record is −10% ≈ $2M on the onboarded lanes in six months; it carries no control. The deferred lanes are a free comparison group: about $5M of spend sits on the deferred remainder of lanes. If the deferred lanes' spend moved −2% on the market alone, the visibility effect is (−10% − (−2%)) × $20M = $1.6M; at −5% it is $1.0M. I would pull that before I defend a causal claim. VERIFY-WITH-RAJESH whether such a comparison was run.

STATISTICAL SPINE — PARETO, GRAIN, GATE AND CONTROL (EXTRA TABLES)

The record: 597 lanes = 80% of spend; completeness 60% → 95%; gate ≥95% valid ASN; freight −10% ≈ $2M in six months. The rows below are my modeled or illustrative arithmetic for a statistician's questions — labeled row by row. Cohort sizes and the number of cohorts are not in the record and are not quoted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Pareto fit through the record point	`S(k) = (k ÷ 1,000)^a with S(597) = 0.80 → a = ln 0.80 ÷ ln 0.597 = 0.4326`	one modeled curve through the one record point	a = 0.4326
2	Spend share at 300 lanes	`(0.300)^0.4326 = 59.4%`	modeled	59.4%
3	Wave 2 (~200 lanes, to 797)	`S(797) − 0.80 = 90.7% − 80.0% = 10.7%`	modeled; ~200 next wave is record	+10.7% of spend
4	Remainder (~200 lanes)	`1 − S(797) = 9.3%`	modeled; the remainder ≈ 20% of spend deferred is a user anchor	9.3% of spend
5	Marginal lane at the cut	`dS/dk = a × S ÷ k = 0.4326 × 0.80 ÷ 597 = 0.058% of spend per lane`	modeled	0.058% / lane
6	Completeness grain, independent misses	`0.60⁴ = 13.0% → 0.95⁴ = 81.5% of shipments fully complete`	four milestones per shipment (illustrative)	13% → 81.5% complete shipments
7	Completeness grain, bounds	`union bound at 95%: 1 − 4 × 0.05 = 80%; ceiling = 95%; at 60%: floor 0%, ceiling 60%`	no independence assumed	shipment-level at 95%: 80%–95%

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Gate: 38/40 valid ASN	`observed 95.0%; one-sided 95% lower bound (Clopper–Pearson) = 85.1%`	illustrative test sizes — cohort sizes are not in the record	85.1%
2	Gate: 40/40 valid ASN	`observed 100.0%; one-sided 95% lower bound (Clopper–Pearson) = 92.8%`	illustrative test sizes — cohort sizes are not in the record	92.8%
3	Gate: 95/100 valid ASN	`observed 95.0%; one-sided 95% lower bound (Clopper–Pearson) = 89.8%`	illustrative test sizes — cohort sizes are not in the record	89.8%
4	Gate: 190/200 valid ASN	`observed 95.0%; one-sided 95% lower bound (Clopper–Pearson) = 91.7%`	illustrative test sizes — cohort sizes are not in the record	91.7%
5	Gate: 194/200 valid ASN	`observed 97.0%; one-sided 95% lower bound (Clopper–Pearson) = 94.2%`	illustrative test sizes — cohort sizes are not in the record	94.2%

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
6	Gate: 196/200 valid ASN	`observed 98.0%; one-sided 95% lower bound (Clopper–Pearson) = 95.5%`	illustrative test sizes — cohort sizes are not in the record	95.5%
7	Gate: 490/500 valid ASN	`observed 98.0%; one-sided 95% lower bound (Clopper–Pearson) = 96.6%`	illustrative test sizes — cohort sizes are not in the record	96.6%
8	Implied spend base	`$2M ÷ 10% = $20M; total spend = $20M ÷ 0.80 = $25M; deferred = $5M`	derived from the record pair and S(597) = 80%	$5M deferred spend
9	Control: deferred lanes drift 0% / −2% / −5%	`(−10% − drift) × $20M = $2.0M / $1.6M / $1.0M`	illustrative difference-in-differences; the record has no control	$1.6M at −2%

BUSINESS IMPACT MODEL — KPI TREE, NUMBERS, THE MATH

```
Inbound freight spend -10% ~= $2M in 6 months (record)
+- Visibility (stock): completeness 60% -> 95%, high-value lanes 100%
|    +- routing-guide compliance: off-guide carrier spend caught
|    +- mode discipline: air -> ocean/ground when ETA is trusted
|    +- expedites + detention: chase calls replaced by 214 events
+- Document handling (flow): 850/855/856/940/945/214 by X12, not by hand
+- DQ gate loop: >=95% valid ASN -> cohort activates -> scorecard per lane ->
     defects fixed as data -> harness parameterized -> cohort 3 mostly config -> adoption 8x
+- Scope loop: 597 = 80% spend first -> $ lands month one -> executive funds the next wave
```

DRIVER	BASELINE	AFTER	$	BASIS
Shipment-data completeness	60%	95%	—	record
Lanes live month one	0	597 = 80% of spend	—	record
Freight spend on onboarded lanes	~$20M over the six months (packet-derived)	−10%	≈$2M / 6 mo	record ($2M)
— routing-guide compliance	off-guide unseen	caught by 856/214	~$0.8M	modeled split of the record $2M
— mode discipline	premium modes by habit	ETA trusted	~$0.6M	modeled split
— expedite + detention avoided	blind lanes chased	events replace calls	~$0.6M	modeled split
Manual document handling	~90K docs/yr keyed	X12/XML validated	$0.4M/yr	modeled (90K × 6 min × $45/hr)

If challenged. *"Is the $2M annualized?"* — "No — it's the record as measured: minus ten percent on the onboarded lanes' spend in six months. I keep it as stated rather than doubling it into a run-rate." *"How do you know the split?"* — "I don't, to the dollar — the split is my model of where the ten percent came from, and the three slices sum to the record, never on top of it."

THE MATH — STEP-BY-STEP DERIVATION

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Completeness	`480 / 800 = 60%`	expected = 200 shipments × 4 milestones = 800; received 480 (illustrative volumes; 60% record)	60% — 2 of 5 events missing

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
2	What blindness costs	`off-guide spend unseen · premium modes by habit · chase calls per late shipment`	record problem	no instrument, no lever
3	Manual documents	`597 lanes × ~50 shipments × 3 docs ≈ 90,000 docs/yr keyed by hand`	illustrative volumes	~90K docs/yr

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Spend Pareto	`S(k) = cumulative spend share; S(597) = 80%`	lanes sorted by annual freight spend (record)	597 of 1,000 lanes carry 80% of spend — do them first
2	Cohort gate	`validASN rate ≥ 95% in test before activation`	published to carriers before cohort one (record)	one cohort failed twice on a timestamp format — held both times
3	Long-tail floor	`XML / portal when EDI is absent`	“the standard was the data, not the transport” (record)	small carriers kept inside the standard
4	Completeness after	`760 / 800 = 95%`	illustrative volumes; 95% record	95%; high-value lanes 100%

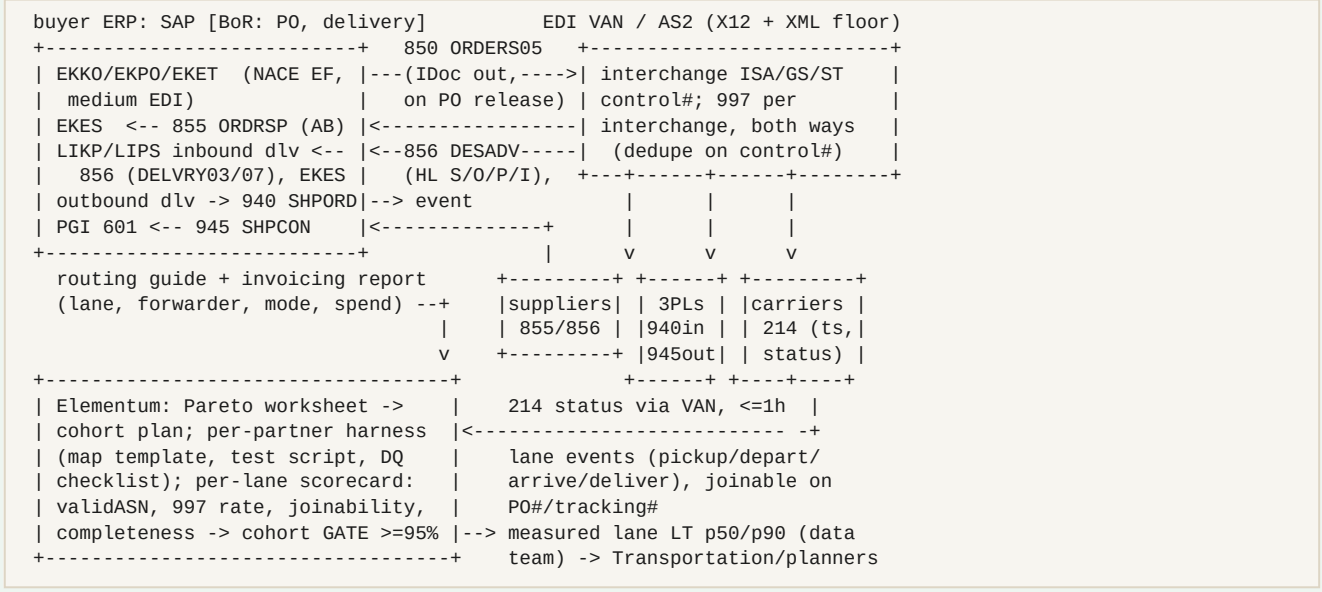

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Shipment-data completeness	60%	95%; high-value lanes 100%	record
2	Lanes live month one	0	597 = 80% of spend	record
3	Freight spend on onboarded lanes	base	−10% ≈ $2M in 6 months	record
4	Document handling	~90K docs/yr keyed	X12/XML validated	modeled

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Implied addressable base	`$2,000,000 / 10% = $20,000,000 of spend over the six-month window`	derived from the record pair, stated as such	≈$20M (six-month base)
2	The record result	`$20M × 10% = $2M in 6 months`	record	≈$2M
3	Slice — routing-guide compliance	`~$0.8M of the $2M`	off-guide spend caught by 856/214 (modeled split)	~$0.8M
4	Slice — mode discipline	`~$0.6M of the $2M`	premium modes → ocean/ground when ETA is trusted (modeled split)	~$0.6M
5	Slice — expedites + detention	`~$0.6M of the $2M`	events replace chase calls (modeled split)	~$0.6M
6	Split check	`0.8 + 0.6 + 0.6 = $2.0M`	the slices decompose the record — they never add to it	= the record $2M
7	Document labor	`90,000 × 6 min = 540,000 min; / 60 = 9,000 h; × $45 = $405,000`	illustrative volumes (modeled add-on)	≈$0.4M/yr

SOLUTION FLOW — THE SYSTEM & DATA MAP

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Shipments/yr on 597 lanes (illustrative)	20,000	30,000	40,000
Minutes per manual document (benchmark)	4	6	8
Loaded coordinator rate (benchmark)	$40	$45	$55
Total modeled $/yr	≈$0.2M	≈$0.4M	≈$0.9M

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

"The measured number is freight spend down ten percent, about two million dollars in six months on the five hundred ninety-seven lanes that carried eighty percent of spend, with completeness sixty to ninety-five percent and adoption eight x. Inside that two million I model roughly eight hundred thousand from catching off-guide carrier spend, six hundred thousand from mode discipline once the ETA was trusted, and six hundred thousand from expedites and detention that chase calls used to cause; those three are my split, the two million is the record. On top of it I model about four hundred thousand a year of document-handling labor that X12 replaced, and that piece is entirely mine."

BEHAVIORAL PACK NEW — FOUR QUESTIONS THIS STORY ANSWERS, FOUR SEPARATE 90-SECOND ANSWERS (EACH FROM A DIFFERENT MOMENT OF THE STORY)

Q1 Tell me about a time you pushed back on a senior leader's request.
HAVE BACKBONE; DISAGREE AND COMMIT

Open (first two sentences): The Global Head of Supply Chain wanted 1,000 lanes of inbound visibility in two months. I told him the schedule would deliver 1,000 lanes of confident wrong data — and showed him the spend curve instead.

STAR (≈90 s): Situation: scope, schedule and quality were all fixed, completeness was 60% and high-value lanes were blind. Task: own the scope analysis and the onboarding standard, influencing an executive two levels above my sponsor. Action: I built the spend Pareto, pre-validated 597 / ~200 / remainder with Transportation and Procurement so no lane owner could contradict the cut, and took it up in spend share, not lane count. He accepted the phased plan off the curve; I committed completely. Result: 597 lanes carrying 80% of spend live in month one; the remainder, about 20% of spend, deferred, priced, behind the same gate.

Land this number: 597 lanes = 80% of spend; ~400 deferred = ~20%. · **Pivot to NACF:** For NACF vendor onboarding I would lead with the volume Pareto and a gate, not a lane count. · **Do NOT say:** Do not name the executive's reaction beyond "accepted the phased plan"; do not quote cohort sizes.

Q2 Tell me about a time you refused to compromise on quality under schedule pressure.
INSIST ON THE HIGHEST STANDARDS

Open (first two sentences): A cohort failed our ≥95% valid-ASN gate twice on a carrier timestamp format. I held it both times.

STAR (≈90 s): Situation: month one, 597 lanes going live, the executive watching. Task: protect the standard without becoming the blocker. Action: the gate was published to carriers before cohort one — a gate that only holds in private is a suggestion; the failing cohort stayed in test, we fixed the format in the mapping template, retested, and activated off the gate. Result: completeness 60% → 95%; the gate is the product — automating dirty data manufactures confident wrong answers.

Land this number: Gate ≥95% valid ASN; held twice; completeness 60% → 95%. · **Pivot to NACF:** For NACF inbound the gate is "valid ASN rate before the vendor lane feeds placement." · **Do NOT say:** Do not say how many lanes were in the failed cohort.

Q3 Tell me about a time you used data to decide where to focus. DIVE DEEP

Open (first two sentences): Lanes differed by orders of magnitude in spend, volume and criticality, so I scored all 1,000 before I scoped anything.

STAR (≈90 s): Situation: a flat 1,000-lane plan would spend most of the effort on the long tail. Task: decide what to do first. Action: spend × criticality × mode × volume scoring, plus a carrier EDI-capability survey, so every lane had a score and a feasibility. Result: 597 lanes = 80% of spend first, ~200 next, the rest behind the same gate — and a method written up as the sourcing SOP.

Land this number: S(597) = 80%; scoring on four factors. · **Pivot to NACF:** Placement analytics starts the same way: rank by volume × cost × criticality, then gate. · **Do NOT say:** Do not call the modeled Pareto fit the record — only the 597 = 80% point is record.

Q4 Tell me about a time you simplified a standard so more people could meet it. INVENT AND SIMPLIFY

Open (first two sentences): Carriers without EDI would have been priced out of the standard, so I made the standard the data, not the transport.

STAR (≈90 s): Situation: some carriers could not produce valid ASNs over EDI. Task: keep the long tail inside one standard. Action: 850/855/856/940/945/214/997 on X12 with an XML or portal floor, parameterized per-partner mapping templates and a test harness instead of bespoke maps. Result: small carriers stayed in the standard; adoption 8×; the harness was reused for later waves.

Land this number: Adoption 8× (user anchor, say so); XML/portal floor. · **Pivot to NACF:** NACF vendors without EDI need the same floor: the standard is the data. · **Do NOT say:** Do not say I built the harness; engineers did to my standard.

SAME STORY, THREE ANGLES NEW — THREE DIFFERENT OPENERS, HEADLINE METRICS AND LPS FROM THE SAME FACTS

(I) DATA / ANALYTICAL

LP: Dive Deep

Open: "597 of 1,000 lanes carried 80% of the spend."

Headline metric: S(597) = 80%; completeness 60% → 95%

- Pareto + four-factor lane scoring + EDI survey.
- Modeled wave 2 ≈ +10.7% of spend (~200 lanes).
- Shipment-grain completeness at 95% events: 80%–95%.
- Freight −10% ≈ $2M (record, not annualized).

(II) CONFLICT / INFLUENCE / BACKBONE

LP: Have Backbone; Disagree and Commit

Open: "I did not take the 1,000-lane ask literally."

Headline metric: 597 live in month one; ~400 deferred, priced

- Took the curve two levels up; pre-validated with owners.
- Committed fully once accepted.
- Held a failing cohort twice.
- Deferral priced: ~20% of spend, same gate.

(III) FAILURE — LEARNING — WHAT I WOULD DO DIFFERENTLY

LP: Insist on the Highest Standards; Learn and Be Curious

Open: "A cohort failed the gate twice on a timestamp format."

Headline metric: gate ≥95% valid ASN; failed twice, held twice

- What I would do differently: a timestamp-format check in the mapping template pre-test. VERIFY-WITH-RAJESH
- Gate as an observed rate, not a bound — I would add the lower bound.
- No control on the −10% — the deferred lanes are one ($1.6M at −2% drift).
- The record is the failure and the hold; the fix is mine to describe, not to inflate.

TRAP DRILLS NEW — THE THREE NASTIEST FOLLOW-UPS A STATISTICALLY RIGOROUS INTERVIEWER THROWS

T1 "Is the $2M causal? What is your control group?"

The numbers: Record: −10% on ≈$20M ≈ $2M, no control. Deferred lanes ≈ $5M of spend; if they drift −2%, effect = (−10% + 2%) × $20M = $1.6M; at −5%, $1.0M.

Say exactly: "The two million is the record as measured on the onboarded lanes — it has no control. The four hundred deferred lanes, about five million dollars of spend, are the natural comparison; if they drifted two percent on the market alone, the visibility effect is about one point six million, and I would pull that before defending causality."

T2 "A ≥95% valid-ASN gate — what sample size makes that meaningful?"

The numbers: 38/40: observed 95%, lower bound 85.1%; 40/40: 92.8%; 190/200: 91.7%; 194/200 (97%): 94.2%; 196/200 (98%): 95.5%.

Say exactly: "The gate was an observed rate in test — ninety-five percent valid ASN. As statistics, ninety-five observed on forty only bounds the true rate above eighty-five, and on two hundred above ninety-two; to show at least ninety-five you need ninety-eight observed on two hundred, and on forty it cannot be shown at all. I would put the bound on the scorecard next to the rate — and I will not quote cohort sizes that are not in the record."

T3 "Completeness 60 → 95% — at which grain, and what does 95% of events mean for shipments?"

The numbers: Four milestones: 0.6^4 = 13.0% → 0.95^4 = 81.5% complete shipments if independent; bounds at 95%: 80%–95%.

Say exactly: "The record is shipment-data completeness, sixty to ninety-five. If that is events, then with four milestones a shipment is fully complete eighty-one percent of the time when misses are independent, and between eighty and ninety-five when they cluster by carrier — so I report both, and I would confirm the grain before quoting a shipment-level figure."

S19 — DESIGN CASE · Walmart Marketplace pre-purchase delivery — the delivery promise: one governed buffer dial instead of a flat 1.10 days — fast-promise share 7.6% → 39.6% at the held 95% floor (design model) NEW

DESIGN CASE — not a delivered result. Built from my own interview-prep materials for a Walmart Marketplace pre-purchase delivery-experience role (requisition R-2596147: war book, Tech Ops WBR deep-dive and an Excel Solver model marked “ILLUSTRATIVE interview model · do not quote $ as a Walmart actual”, Aug–Sep 2026). No client engaged me, nothing was deployed, and every number below is prefixed “in the model.” Voice: “I designed / in the model / here is how I would run it.” **Lived record for this theme — Apple F4 (Elementum, record):** I replaced carrier-brochure lead times with measured transit distributions on 200 lanes, set the promise at the 99th percentile per lane, held 99% lead-time accuracy, and freed 580,000 units / about $1.5M of inventory carrying cost; the drift flag and refresh cadence kept the distributions honest. If asked “did this ship?” say: “No — this is a design case I worked through; the lived version of promise-at-the-tail is my 200-lane program.”

LPs this story serves here: Invent and Simplify (one dial) · Customer Obsession (a promise the customer can rely on) · Dive Deep (the Φ(5.0) vs Φ(0.69) audit) · Insist on the Highest Standards (shadow gate, peak re-solve)
Process family: Deliver seam — pre-purchase promise policy for seller-fulfilled delivery (Walmart Marketplace pre-purchase delivery, design case for role R-2596147 Pre-Purchase Delivery Experience)

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH NEW

- **Dive Deep** — I decomposed the 95.8% headline into two cohorts: the flat 1.10-day buffer bought Φ(5.0) — near-certainty — on the tightest cohort and Φ(0.69) ≈ 75% on the widest.
- **Invent and Simplify** — I replaced a hundred model micro-decisions with one governed dial, b = k·σ with k = 1.645, that a business owner can read every Monday.
- **Customer Obsession** — The customer blames the marketplace, not the seller, when Thursday becomes Saturday — the floor was a promise kept 95 times in 100 on every cohort.
- **Insist on the Highest Standards** — Four consecutive shadow weeks before any displayed promise, a published promotion bar and a warm rollback; and every figure said “the model” in the same breath.

Honesty label. A design case, not a client design case: I worked it through for a Walmart Marketplace pre-purchase delivery role, on the marketplace's seller-fulfilled delivery program, where the marketplace prints "Get it by Thursday" on inventory that sits in sellers' buildings. I designed the promise-policy workstream on paper: the decomposition, the buffer-policy alternatives, the validation gates and the governance design. In the design, the marketplace's promise-engineering and data-science teams would own the promise engine and the transit models — nothing was built or deployed (the only platform I personally configured remains Manhattan DOM). The twelve-cohort book behind every number is my own Solver model (illustrative, 12 lane cohorts, ~1M orders/week), built so the argument could happen in numbers instead of adjectives. The lived record for promise-at-the-tail is Apple F4 (200 lanes, p99 promise, 99% accuracy, 580K units / ~$1.5M carrying cost released).

60-SECOND PITCH

"**Situation.** A marketplace client promising delivery dates on inventory it never touches: promised date = order time + seller handling + predicted transit + a safety buffer — and the buffer was a flat 1.10 days on every lane regardless of how variable the lane was. In the design model — twelve lane cohorts, about a million orders a week, transit spread from 0.22 to 1.60 days — that flat buffer printed 95.8% accuracy but put only 7.6% of orders on a fast promise, because dense metro lanes were over-insured and fat-tailed rural lanes under-insured at the same time. **Task.** In the case I designed the promise policy: own the decomposition, the alternatives, the gates and the governance recommendation; the marketplace's data science and engineering did not report to me. **Action.** Discovery: the buffer-waste audit — the flat buffer bought Φ(5.0), near-certainty, on the tightest cohort and only Φ(0.69) ≈ 75% on the widest. Plan & Design: four policies on one comparison table — uniform, σ-proportional with one governed dial, minimum-days at the floor, profit-optimal on priced breach economics. Build & Test: b = 1.645σ holds 95% on every cohort by construction; the equimarginal check proved the optimum; the Q4 drill showed a frozen summer dial breaking the floor. Cutover: four shadow weeks against logged live orders before any displayed promise. Hypercare: the dial published in the weekly review header, re-solved before peak. **Result.** Primary metric (in the model): fast-promise share — **7.6% → 39.6%, +32 points at the held 95% floor**; average promised day 3.09 → 2.75; +$255K a week, about $13.3M a year — all on the illustrative book, and I say 'the model' in the same breath."

20-SECOND VERSION NEW

A flat 1.10-day buffer printed 95.8% accuracy and put 7.6% of orders on a fast promise; one governed dial, b = 1.645σ, kept every cohort at 95% and lifted fast-promise share to 39.6% — +32 points on the case's illustrative model, never a production claim.

NACF BRIDGE — ONE SENTENCE

NACF promise and appointment buffers should be risk-proportional, not flat: buffer = k × the lane’s own σ, one published dial, re-solved before peak — the same logic as INV-B’s z·σ·√LT.

SITUATION / TASK — WHERE IT OCCURRED, WHEN IT HAPPENED, WHY IT IS IMPORTANT

S — A design case I worked through on Walmart Marketplace's seller-fulfilled delivery program (prep for role R-2596147, 2026). The client underwrites a delivery promise on execution it does not own: the seller picks and packs, a carrier it only partially controls carries, and the customer blames the marketplace — not the seller — when Thursday becomes Saturday. The promise identity is a sum: promised date = order time + configured handling + predicted transit + buffer; the promise is kept when the handling error plus the transit error fit inside the buffer. The incumbent buffer policy was uniform — about 1.10 days on every lane — set once, owned by nobody between reviews.

T — Lead the promise-policy workstream: decompose where the incumbent buffer was wasted and where it was thin, put priced alternatives on one table, design the validation gates, and leave the marketplace a governance instrument — not a tuning habit. Everything quantitative ran on the case's illustrative model: twelve lane cohorts spanning σ = 0.22 days (metro two-day) to 1.60 days (mountain rural), about a million orders a week.

Why it mattered: padding fails silently and cutting fails loudly, so every promise system drifts slow — the orders that never happened because the promise read five days file no tickets. The economics were stated up front and carried on every page: a breach costs about $12 (contact + refund risk + trust decay) against about $6.50 of contribution margin — both the model's stated assumptions, never a measured P&L. Left unfixed: the marketplace keeps paying for insurance it doesn't need on tight lanes while underwriting known losses on loose ones, and the speed-versus-accuracy dial keeps being set implicitly by whoever tuned the last model.

The metrics on the table, with their baselines (all illustrative-model values): fast-promise share (orders promised in ≤2 days) — 7.6%; portfolio promise accuracy — 95.8% against a 95% floor; average promised day — 3.09; weekly modeled profit — $5.69M; and no governed owner of the speed-accuracy trade — the real baseline.

ACTION — WHAT I PERSONALLY OWNED, HOW I DID IT, WHO ELSE WAS INVOLVED

A — Five gated phases, written as a design arc (the model, the table and the gates are the design case's materials (nothing delivered); no phase touched a production system — the marketplace's teams built, I designed and governed):

- **Discovery** — wrote the promise identity and the accuracy factorization (accuracy ≈ P(seller ships in window) × P(carrier meets transit) × Φ(buffer/σ)); built the buffer-waste audit — days delivered early on kept promises, ranked by waste × volume — and the two-line indictment of the flat buffer: 1.10 days is 5.0 standard deviations on the tightest cohort and 0.69 on the widest. *Exit bar:* the marketplace's own cohort table agreed in the room; "how much buffer" retired as a question, replaced by "where should it sit."
- **Plan & Design** — four policies written onto one comparison table on the same cohort set: A uniform (incumbent), B σ-proportional with one governed dial (b = k·σ), C minimum-promised-days at the floor (analytic optimum), D profit-optimal on the priced breach economics; the gates designed — shadow mode, a promotion bar, a rollback that keeps the incumbent computable. *Exit bar:* the table signed as the decision instrument; the dial (k) named as a governed, published policy instrument with an owner.
- **Build & Test** — the marketplace's data-science team computed the table; I owned the proofs: Φ(1.645) = 0.95 holds the floor on every cohort by construction; the equimarginal condition for C (φ(b/σ)/σ equal across cohorts) verified to machine precision; the Q4 drill — σ inflated ~1.45× — showed the frozen summer dial printing 91.9%, below the floor. *Exit bar:* every policy's accuracy, speed and modeled profit reproduced independently by the marketplace's team; the peak-regime rule written.
- **Cutover / Go-Live (design)** — shadow mode: the challenger policy computed and logged per order, never displayed, for four consecutive weeks; promotion only if would-be accuracy held the floor on logged live orders with no rise in contact signals. *Exit bar:* promotion bar published before the first shadow week; rollback = one flag back to the incumbent, kept warm.
- **Hypercare / Close** — the governance handoff: k printed in the weekly review header every Monday; tail metrics (p90 error, buffer-exceedance) on the page next to the average; the buffer-waste line standing; k re-solved per regime — published in October for peak, never frozen through it. *Exit bar:* the marketplace's business owner — not data science — named as the dial's owner; the design case ends on the instrument, not on a tuning.

The marketplace's promise-engineering team owned the engine and its latency budget; their data-science team owned the transit models and σ estimates; their finance partner owned the breach price. Mine: the factorization, the waste audit, the four-policy table, the equimarginal and Q4 proofs, the shadow-mode gates and the governance design — the reframe from "a hundred ML micro-decisions" to one auditable dial a business owner reads on a Monday.

The obstacle was the room's instinct that accuracy at 95.8% meant the policy was healthy — the decomposition had to beat a green headline. The two-cohort arithmetic did it: near-certainty bought where σ was tiny, a coin-flip-plus where σ was fat. The decision I challenged: data science wanted per-lane learned buffers — more model, more value, invisible governance. I priced the difference and recommended the one-dial policy first: it captures most of the value, it is auditable, and σ improvements flow into speed automatically and visibly. The no went into the comparison table as a priced row, not a meeting minute.

RESULTS — HOW SUCCESS WAS MEASURED: $ · # · % · TIME · CUSTOMER · QUALITY

R — Primary metric (in the model): fast-promise share 7.6% → 39.6% (+32 points) at the identical 95% accuracy floor; average promised day 3.09 → 2.75; +$255K/week ≈ $13.3M/yr — every figure from the illustrative model, said with "the model" in the same breath.

- **$** — +$255K/wk vs the uniform policy ≈ $13.3M/yr (modeled on the illustrative ~1M-order book); the profit-optimal frontier (policy D: 97.8% accuracy, $6.07M/wk, ≈ +$20M/yr vs uniform) handed to the marketplace's finance partner as a priced governance decision — shown, never claimed, never merged with the $13.3M.
- # — Twelve lane cohorts, ~1M orders/week, σ from 0.22 to 1.60 days; four policies on one table; one governed dial, k = 1.645 (illustrative model; the table and the dial are the design case's design record).

- **%** — Fast-promise share +32.0 points at a held 95.0% floor; the incumbent's hidden split exposed: Φ(5.0) ≈ 99.99997% on the tightest cohort against Φ(0.69) ≈ 75.4% on the widest (model).
- **Time** — Average promised day 3.09 → 2.75 (−0.34); the tightest cohort's buffer 1.10 → 0.36 days; the widest cohort's buffer 1.10 → 2.63 days — longer on purpose, to stop underwriting known losses (model).
- **Customer** — The fast promise shown where it can be kept and withheld where it can't; the Q4 re-solve rule so peak variability never silently breaks the floor the customer experiences (design-case record (not delivered)).
- **Quality** — The equimarginal check as the solver's own proof of optimality; p90 error and buffer-exceedance on the review page next to the mean, so a better average can never hide a worse tail (design-case record (not delivered)).

Against the goal stated above: more fast promises without breaking the floor — +32 points at exactly 95.0%, a promise a third of a day shorter on average, and the speed-versus-accuracy trade converted from an implicit model parameter into one governed, published dial. The trade was explicit and priced: the widest cohorts got honestly slower promises so the whole book could get kept ones; nothing was bought with accuracy.

L6 LEVEL EVIDENCE — what the interviewer pattern-matches against the Amazon L6 functional rubric

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	Nobody owned the speed-vs-accuracy trade; I defined it as one dial with a floor and an owner.
Scope & influence	Client promise engineering, data science, finance and seller programs — none reporting to me; the “no” to per-lane learned buffers went in as a priced row.
Execution	Four-policy table, two proofs (Φ(1.645) floor and equimarginal), Q4 drill, shadow gate and rollback designed.
Impact	+32 pts fast-promise share at a held 95% floor; +$255K/wk ≈ $13.3M/yr — all design model, labeled as such.
Process improvement	k published weekly and re-solved per regime — governance, not tuning.
Complexity	Twelve cohorts with σ from 0.22 to 1.60 days; heavy tails; a peak regime that breaks a frozen dial.
Root cause	A flat buffer ignores variance: it over-insures dense lanes and under-insures fat-tailed ones at once.

THE FIVE FACETS NEW — data analysis · solution design · math & data logic · implementation · probe questions; each labeled so the interviewer can see all five are present

1 · Data analysis	Data: twelve lane cohorts, σ 0.22–1.60 days, ~1M orders/week (the case's illustrative model); promise identity = order + handling + transit + buffer. Revealed: flat 1.10 d = 5.0σ on the tight cohort, 0.69σ on the wide one.
2 · Solution design	Options: A uniform · B σ-proportional with one dial · C minimum-days at the floor · D profit-optimal. Chosen: B first (auditable, one dial); D shown and never claimed.
3 · Math & data logic	Math: P(kept) = Φ(b/σ); b = kσ with Φ(k) = 0.95 → k = 1.645; tight 0.36 d, wide 2.63 d; Q4 σ × 1.45 → z = 1.13 → 87.2% per cohort, 91.9% portfolio (in the model); price-of-floor, estimation-error and heavy-tail arithmetic below.
4 · Implementation	Implementation: waste audit → four-policy table → proofs → 4-week shadow → published promotion bar → k in the weekly review header; re-solved in October.
5 · Probe questions	Probe questions: σ estimation error · heavy tails · why not policy D · how the floor behaves at peak — see Trap Drills.

PROBING — CHALLENGE Q&A (MASTER RECORD) PLUS THE STATISTICAL QUESTIONS

> ***Challenge* — Why did you choose this story to illustrate Dive Deep?**
>
> Because the finding only exists below the headline: portfolio accuracy printed a healthy 95.8%, and the depth — per-cohort z-scores — showed the same policy was simultaneously over-insuring metros at five standard deviations and under-insuring rural lanes at 0.69. A team that stops at the portfolio number never finds thirty-two points of free speed.

***Probing* — Why did you choose to focus on these results? What other results were important?**

The +32 points at a held floor leads because it survives any parameter change — it comes from re-allocating risk, not spending money. Also important: the honest cost (the widest cohorts' promises got longer), the Q4 regime rule, and the governance artifact — a dial the business reads weekly — which outlives any one solve.

***Probing* — You mentioned dollars — what percentage change is that year over year?**

I don't give this one as year-over-year — every dollar here is the model's: +$255K/wk is about 4.5% of the modeled $5.69M weekly contribution, ≈ $13.3M annualized on the illustrative book. There is no production dollar in this design case and I never promote one.

***Probing* — I'm concerned the whole story rests on an illustrative cohort set — tell me more.**

It does, deliberately — the model exists so the argument happens in numbers instead of adjectives. If the real σ looks nothing like the model's, k changes and the lane ranking changes; what survives any parameter set is the structure: buffers should be risk-proportional, the last buffer-day should buy the same accuracy everywhere, and a floor that disagrees with the breach economics is a governance finding.

***Challenge* — What were the lessons learned? What would you have done differently?**

The lesson: padding is not safety — a flat buffer is slow and unsafe at the same time, and only the decomposition shows it. Differently: price the breach bundle with the finance partner in discovery rather than design — the $12-versus-$6.50 conversation is what turned the floor from theology into economics, and it came one phase late.

***Challenge* — How would you implement this at Amazon?**

The same shape at the promise seam: decompose the promise identity, audit where buffer is wasted on kept promises, one governed dial per regime with the tail metrics on the page, shadow before display, re-solve before peak. At Amazon's scale a tenth of a point of buffer waste is real money — which is why the governance matters more than any single solve.

***Challenge* — How did these results compare to your actual goals?**

The goal was more fast promises without breaking the floor. The model delivered +32 points at exactly the floor and a promise a third of a day shorter — and the frontier beyond it (policy D at 97.8%) was handed to Finance as a priced decision rather than smuggled in as a default.

PHASE DEEP-PROBE BANK — Q&A (12). ***Answer the phase asked, then stop.***

Discovery — How did you know discovery was done?

When the room accepted one sentence of arithmetic: the flat 1.10-day buffer is 5.0 standard deviations on the tightest cohort and 0.69 on the widest. Once that was agreed on the marketplace's own cohort table, "how much buffer" was dead as a question and "where should it sit" replaced it.

Why a buffer-waste audit instead of starting from accuracy?

Accuracy printed 95.8% — a healthy-looking headline hiding the split. Waste — days delivered early on kept promises — is where the recoverable speed lives, and it is unarguable because it only counts promises that were kept. Ranked by waste × volume, the audit is the trim roadmap with no new models needed.

Plan & Design — Why four policies instead of recommending one?

Because the marketplace's real decision was governance, not mathematics. A is what you run today; B is one auditable dial; C is the fastest promise the floor allows; D is what the economics want. All four on one cohort set made the trade-offs priced choices instead of expert opinion — and made B's simplicity a visible decision, not a default.

Why recommend B over the profit-optimal D?

D's optimum moves every time the breach price or margin assumption moves, and it is harder to audit. B is one dial a business owner reads on a Monday and it captures most of the value. I recommended running B and letting Finance decide whether to chase the D frontier with its own signature on the $12.

Build & Test — What exactly is the equimarginal check?

The optimality condition for policy C: the marginal accuracy bought by the last unit of buffer — φ(b/σ)/σ — must be equal on every cohort; if a buffer-day buys more accuracy on one lane than another, moving it is free improvement. The solver's output showed the condition holding to machine precision — the model proving its own optimum.

What was the Q4 drill and what did it change?

Inflate every cohort's σ by ~1.45× — the model's peak regime — and hold the summer dial: portfolio accuracy printed 91.9%, under the floor (on a single lane taking the full inflation, the whiteboard version is Φ(1.645/1.45) = Φ(1.13) ≈ 87% — the portfolio mix lands at 91.9%). The drill wrote the rule: k is re-solved and published before peak, never frozen through it.

Why normal errors — freight tails are skewed?

Said before anyone asked: the normal is the whiteboard version; the production recommendation was the empirical quantile per lane. The normal makes the argument legible; the quantile makes it true. Nothing in the recommendation depends on normality — only the clean Φ numbers do.

Cutover — What was the promotion bar out of shadow mode?

Four consecutive shadow weeks with would-be-promise accuracy at or above the floor on logged live orders and no rise in contact signals. A policy that can't clear its own floor in shadow has no business touching a displayed date — the same rehearse-before-commit discipline as my mock cutovers (S18).

What was the rollback?

The incumbent uniform buffer stayed computable the whole time — one flag back. A promise policy is the easiest class of change to reverse if you keep the old policy warm, and the easiest to make irreversible if you don't.

Hypercare — Why publish the dial in the review header?

Because k *is* the speed-versus-accuracy trade, and a trade the business can't see is a trade it didn't agree to. One number in the header every Monday makes the floor a standing decision instead of a buried parameter.

What keeps the policy honest after handoff?

Three standing lines on the review page: the dial, the tail metrics (p90 error and buffer-exceedance) next to the average, and the buffer-waste line. A policy whose tail and waste are public decays far more slowly than one graded on its mean.

Cross-phase — Where did you trade scope for the date? What did you refuse?

Traded: per-lane learned buffers deferred in favor of the one dial — sophistication for governance, knowingly leaving model value on the table for the first cycles. Refused: promoting on the model's average error (the tail breaks promises, so the tail went on the page), and any record dollar — the book is illustrative and I said so in every read-out.

Analytics — What does the floor cost? Price each step.

On the widest cohort (σ = 1.60 d) the buffer is 2.63 d at a 95% floor, 3.14 d at 97.5% (+0.50 d) and 3.72 d at 99% (+1.09 d); on the tightest cohort (σ = 0.22) the same steps cost 0.07 d and 0.15 d. The dial is linear in σ — so a point of floor is nearly free on dense lanes and expensive on rural ones, which is the whole argument for a risk-proportional rule. Engagement model.

Analytics — Your σ is estimated. What does that do to the floor?

With n orders in a cohort, σ̂ has relative standard error 1 ÷ √(2(n − 1)): 7.1% at n = 100, 2.2% at n = 1,000. If σ̂ is one SE low, a dial of 1.645 realises z = 1.645 ÷ (1 + SE): 1.54 at n = 100 → 93.8%; 94.6% at n = 1,000. Holding the floor within half a point at a one-SE miss needs about 584 orders per cohort per window. At about a million orders a week that is trivially met; the real exposure is regime change, which is why Q4 is the drill.

Analytics — Normal errors — what if the errors are heavy-tailed?

Production uses the empirical quantile; the whiteboard uses the normal. As a sensitivity, take Student-t errors with 5 degrees of freedom scaled to the same σ: the 95% quantile is 1.561σ, below 1.645 — the normal dial is conservative there and delivers 95.6% — but the 99% quantile is 2.607σ, above 2.326, so a normal 99% dial would deliver only 98.5%. The heavier the tail the more the empirical quantile matters at the high floors.

Analytics — With a million orders a week, is the weekly accuracy noise a problem?

No: the standard error of a 95% weekly accuracy on 1,000,000 orders is √(0.95 × 0.05 ÷ 1,000,000) = 0.022 points; on a 100,000-order cohort 0.069. A reading of 91.9% in Q4 is not noise — it is a σ regime change. At this scale the question is never “is it significant,” it is “which factor moved.”

STATISTICAL SPINE — PRICE OF THE FLOOR, Σ-ESTIMATION ERROR, HEAVY TAILS (EXTRA TABLES)

The design model is the in the model; these tables are my sensitivity arithmetic on the same cohorts and dial — every figure design-model or textbook-normal, none a production measurement.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Floor 90% → k	`Φ(k) = 0.90 → k = 1.2816`	standard normal table	tight 0.28 d · wide 2.05 d
2	Floor 95% → k	`Φ(k) = 0.95 → k = 1.645`	in the model dial	tight 0.36 d · wide 2.63 d
3	Floor 97.5% → k	`Φ(k) = 0.975 → k = 1.96`	standard normal table	tight 0.43 d · wide 3.14 d
4	Floor 99% → k	`Φ(k) = 0.99 → k = 2.326`	standard normal table	tight 0.51 d · wide 3.72 d
5	Price of 95% → 97.5% (wide cohort)	`(1.96 − 1.645) × 1.60 = 0.50 d`	σ = 1.60 d (illustrative model)	+0.50 d of promise
6	Price of 95% → 99% (wide cohort)	`(2.326 − 1.645) × 1.60 = 1.09 d`	σ = 1.60 d (illustrative model)	+1.09 d of promise
7	Incumbent accuracy, tight / wide	`Φ(1.10 ÷ 0.22) = Φ(5.0) ≈ 100%; Φ(1.10 ÷ 1.60) = Φ(0.69) = 75.4%`	flat buffer b = 1.10 d	75.4% on the wide cohort

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	σ̂ standard error, n = 100	`1 ÷ √(2 × 99) = 7.1%`	large-sample approximation	7.1%
2	Realised accuracy at a one-SE miss, n = 100	`z = 1.645 ÷ (1 + 0.0711) = 1.536; Φ = 93.8%`	σ̂ one SE below the truth	93.8% (floor 95%)
3	Same, n = 1,000	`z = 1.645 ÷ (1 + 0.0224) = 1.609; Φ = 94.6%`	same method	94.6%
4	Orders needed for ≥ 94.5% at a one-SE miss	`z* = Φ⁻¹(0.945) = 1.5982; 1 + SE = 1.645 ÷ 1.5982; n = 1 + 1 ÷ (2 × SE²) = 584`	design arithmetic	≈ 584 orders per cohort-window
5	Heavy tails, t_5 scaled to unit variance	`95%: 2.015 ÷ √(5/3) = 1.561; 99%: 3.365 ÷ √(5/3) = 2.607`	Student-t table; sensitivity only	normal dial delivers 95.6% at 95%, 98.5% at 99%
6	Q4 regime, frozen dial	`z = 1.645 ÷ 1.45 = 1.134; Φ = 87.2% per fully-inflated cohort`	σ × 1.45 (illustrative model)	87.2% per cohort; 91.9% portfolio (in the model)
7	Accuracy noise at scale	`√(0.95 × 0.05 ÷ 1,000,000) = 0.022 pts; at 100,000: 0.069 pts`	binomial	noise ≪ any real signal

BUSINESS IMPACT MODEL — KPI TREE, NUMBERS, THE MATH

```
Marketplace contribution (modeled, illustrative book)
+- Conversion on fast promises (flow) -> fast share 7.6% -> 39.6%
|    fast share = SUM_cohorts volume x [handling + transit_pred + buffer <= 2d]
|    (loop) faster promise -> higher CVR -> more orders -> more seller GMV
+- Breach cost (flow, $/order) -> floor held at 95.0%
|    breach EV = (1 - Phi(b/sigma)) x $12   [contact + refund risk + trust decay]
+- Buffer waste (stock: days early on kept promises) -> harvested on tight lanes
+- Governance -> one dial k, published weekly; re-solved per regime (Q4)
+- Frontier (not claimed) -> policy D: 97.8% accuracy, +$0.38M/wk vs A
```

DRIVER	BASELINE	AFTER	$/WK	BASIS
Weekly modeled profit, policy A (uniform 1.10d)	$5.69M	—	$5.69M	illustrative model output
Weekly modeled profit, policy B (b = 1.645σ)	—	$5.94M	$5.94M	illustrative model output
Fast-promise share	7.6%	39.6% (+32 pts)	inside the profit lines	illustrative model
Average promised day	3.09	2.75	inside the profit lines	illustrative model
Frontier: policy D (profit optimum)	—	97.8% accuracy, $6.07M/wk	+$0.38M vs A	illustrative; handed to Finance, never claimed

If challenged. *"Your whole result is a model."* — "Yes, and I say so in the same breath — the model exists so the marketplace's decision could be quantitative. The structure survives any parameter set: risk-proportional buffers, equal marginal accuracy per buffer-day, a floor reconciled with the breach economics. The parameters are the marketplace's to correct." *"Why is the $12 breach cost credible?"* — "It's the model's stated assumption — a contact, refund and return risk, and trust decay bundled — put on the table precisely so Finance could attack it. At $12 the profit optimum holds 97.8% accuracy; if Finance believes $6, the optimum falls toward the floor. Fight about the number, not the theology." *"Did any of this ship?"* — "The design case produced, on paper, the policy table, the gates and the governance design; the marketplace's teams owned the build. I claim the instrument and the modeled deltas, labeled — never a production P&L."

THE MATH — STEP-BY-STEP DERIVATION

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	The promise identity	`EDD = t_order + handling + transit_pred + b; kept ⇔ (handling_err + transit_err) ≤ b`	per order; b = buffer in days (in the model identity)	the buffer is the only policy term
2	Kept-promise probability per lane	`P(kept) = Φ(b / σ)`	ε ~ N(0, σ²) per cohort — whiteboard version; production uses the empirical quantile (in the model)	accuracy is a function of b and σ only
3	Incumbent buffer	`b = 1.10 days on every lane`	uniform policy A (illustrative model)	1.10 d everywhere
4	Tightest cohort, z-score	`z = b / σ = 1.10 / 0.22 = 5.0; Φ(5.0) ≈ 0.9999997`	metro cohort σ = 0.22 d (illustrative model)	near-certainty bought — promise needlessly slow
5	Widest cohort, z-score	`z = 1.10 / 1.60 = 0.6875; Φ(0.69) ≈ 0.754`	mountain-rural cohort σ = 1.60 d (illustrative model)	≈75.4% kept — a known-loss book

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
6	Portfolio print	`accuracy 95.8% · fast share 7.6% · avg promised day 3.09 · profit $5.69M/wk`	order-weighted across 12 cohorts, ~1M orders/wk (illustrative model)	a green headline hiding both failures
7	The asymmetry	`padding fails silently (lost conversion files no ticket); cutting fails loudly (breaches do)`	in the model — why the system drifted slow	bias toward slow, unowned

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	One governed dial	`b_lane = k × σ_lane; Φ(k) = floor ⇒ k = 1.645 for 95%`	Φ(1.645) = 0.95 under normal errors (in the model design)	k = 1.645, one number for the book
2	Tightest cohort re-buffered	`b = 1.645 × 0.22 = 0.36 days`	σ = 0.22 d (illustrative)	buffer 1.10 → 0.36 d; 0.74 d of speed harvested
3	Widest cohort re-buffered	`b = 1.645 × 1.60 = 2.63 days`	σ = 1.60 d (illustrative)	buffer 1.10 → 2.63 d — slower on purpose, kept honest
4	Every cohort at the floor	`P(kept) = Φ(1.645 × σ / σ) = Φ(1.645) = 0.95 on each cohort`	by construction (design)	95.0% everywhere; no cohort subsidizes another
5	Portfolio after	`accuracy 95.0% · fast share 39.6% · avg day 2.75 · profit $5.94M/wk`	illustrative model output, policy B	+32 pts fast share at the floor
6	Equimarginal proof (policy C)	`φ(b/σ)/σ equal across all 12 cohorts (spread < 1e-15)`	solver optimality condition (in the model)	the last buffer-day buys the same accuracy everywhere
7	Peak regime rule	`σ_Q4 ≈ 1.45 × σ; frozen k ⇒ z = 1.645/1.45 = 1.13; Φ(1.13) ≈ 0.87 per fully-inflated lane; portfolio prints 91.9% < 95%`	Q4 drill (illustrative model)	k re-solved and published in October, never frozen
8	Shadow gate	`4 consecutive weeks logged ≥ floor, contacts flat → promote; else hold`	promotion bar (design)	rehearse against reality before any displayed date

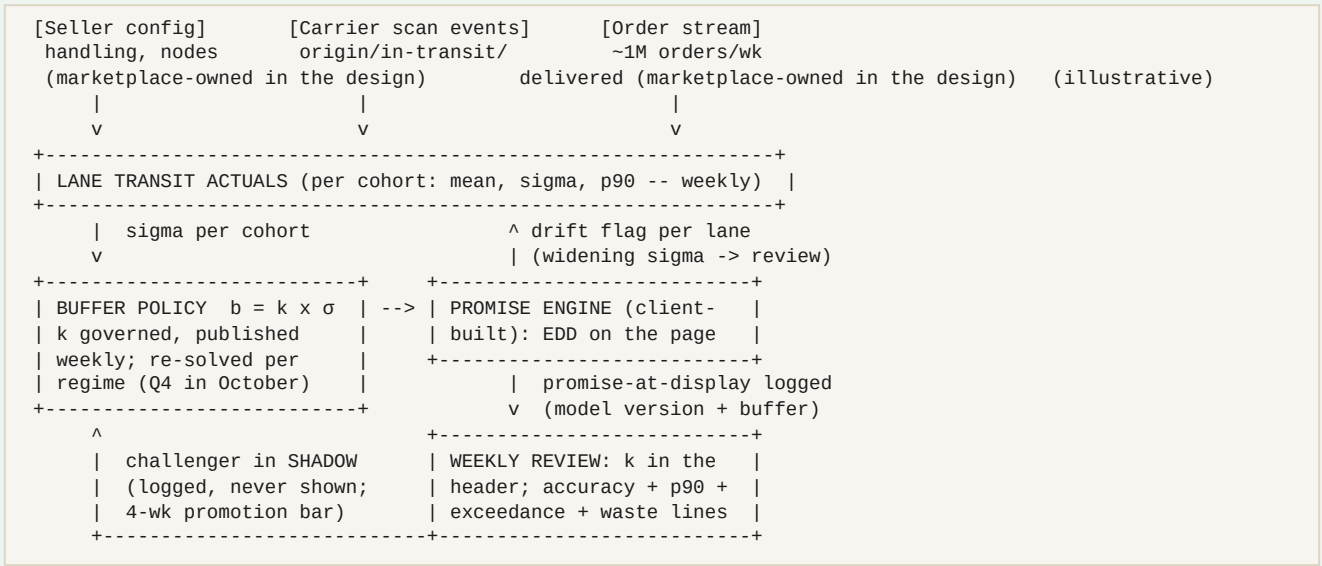

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Fast-promise share (≤2-day)	7.6%	39.6% (+32 pts)	illustrative model
2	Portfolio promise accuracy	95.8% (split: ~100% / 75.4%)	95.0% — the floor, held on every cohort	illustrative model
3	Average promised day	3.09	2.75 (−0.34)	illustrative model
4	Weekly modeled profit	$5.69M	$5.94M (+$255K)	illustrative model
5	Owner of the speed-accuracy trade	implicit, in the last model tune	one governed dial, published weekly, re-solved per regime	design-case record (not delivered)

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Weekly profit, policy A	`$5,690,000 / wk, taken from the model`	illustrative model output	$5.69M/wk
2	Weekly profit, policy B	`$5,940,000 / wk, taken from the model`	illustrative model output	$5.94M/wk
3	Weekly delta	`$5,940,000 − $5,690,000 = $250,000 (the model's precise print: +$255K)`	rows 1, 2 (illustrative)	≈ +$255K/wk
4	Annualized	`$255,000 × 52 = $13,260,000`	row 3 × 52 weeks (modeled)	≈ $13.3M/yr — "the model," said in the same breath
5	Frontier: policy D delta	`$6,070,000 − $5,690,000 = $380,000/wk; $380,000 × 52 = $19,760,000`	illustrative model output; ×52 modeled	≈ $20M/yr — handed to Finance, never claimed
6	Why D holds 97.8%	`breach EV $12 > margin-per-promise-day trade at $6.50 ⇒ optimum above the 95% floor`	$12 and $6.50 are the model's stated assumptions	the floor and the economics disagree — a governance finding
7	Headline	`≈ $13.3M/yr modeled; record dollars: none`	rows 3–4	≈ $13.3M/yr, always labeled

SOLUTION FLOW — THE SYSTEM & DATA MAP

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Breach cost bundle (model assumption)	$6	$12	$18
Profit-optimal accuracy (policy D)	falls toward the 95% floor	97.8%	above 97.8% — accuracy gets cheaper to justify
σ dispersion across cohorts (drives the free lunch)	narrow — gain shrinks	0.22–1.60 d	wider — gain grows
Fast-share gain from B vs A	≈ +10 pts	+32 pts	≈ +40 pts
Modeled $/yr vs uniform	≈ $4–5M	≈ $13.3M	≈ $20M (the D frontier)

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

"On the case's illustrative book — twelve lane cohorts, about a million orders a week — moving from a flat 1.10-day buffer to risk-proportional buffers with one governed dial bought thirty-two points of fast-promise share at the identical ninety-five percent accuracy floor, took a third of a day off the average promise, and was worth about two hundred fifty-five thousand dollars a week, call it thirteen million a year. Every one of those numbers is the model's, and I say that in the same breath — there is no production dollar here. What I claim as mine is the instrument: the decomposition, the four-policy table, the shadow gates, and a dial the business reads every Monday."

BEHAVIORAL PACK NEW — FOUR QUESTIONS THIS STORY ANSWERS, FOUR SEPARATE 90-SECOND ANSWERS (EACH FROM A DIFFERENT MOMENT OF THE STORY)

Q1 Tell me about a time a headline metric hid the real problem. DIVE DEEP

Open (first two sentences): Promise accuracy printed 95.8% — green — and the room believed the policy was healthy. I split it into two cohorts.

STAR (≈90 s): Situation: a marketplace promised delivery dates on inventory it never touched, with a flat 1.10-day buffer on every lane. Task: decompose where the buffer was wasted and where it was thin. Action: z = buffer ÷ σ — 1.10 ÷ 0.22 = 5.0 on the tightest cohort (near-certainty, a needlessly slow promise) and 1.10 ÷ 1.60 = 0.69 on the widest (75.4% kept, a known-loss book). The average was hiding both failures. Result: the question changed from “how much buffer” to “where should it sit,” and the one-dial policy followed. All of this is the case's illustrative model.

Land this number: Φ(5.0) vs Φ(0.69) = 75.4%; headline 95.8%. · **Pivot to NACF:** NACF appointment and ASN promise lanes: check the tightest and widest vendor lanes before trusting the average. · **Do NOT say:** Do not call any figure a production result.

Q2 Tell me about a time you simplified a complex decision. INVENT AND SIMPLIFY

Open (first two sentences): Data science wanted per-lane learned buffers. I recommended one dial — b = k·σ — and priced the difference.

STAR (≈90 s): Situation: a hundred ML micro-decisions, invisible governance. Task: leave the marketplace an instrument, not a tuning habit. Action: four policies on one table — uniform, σ-proportional with one dial, minimum-days at the floor, profit-optimal — and the one-dial policy first because it captured most of the value and was auditable; σ improvements flow into speed automatically. The “no” to per-lane models went into the table as a priced row. Result: fast-promise share 7.6% → 39.6% at the held 95% floor on the model.

Land this number: +32 pts at a 95% floor; k = 1.645. · **Pivot to NACF:** A NACF dial a manager can read on Monday beats a model nobody can audit. · **Do NOT say:** Do not claim I built the promise engine; the marketplace’s teams did.

Q3 Tell me about a time you protected the customer’s experience when the numbers could have been juiced. CUSTOMER OBSESSION

Open (first two sentences): Fast-promise share can be juiced by bleeding accuracy, so I pinned accuracy at 95% on every cohort and let speed float.

STAR (≈90 s): Situation: the customer blames the marketplace when Thursday becomes Saturday. Task: more fast promises without breaking the floor. Action: floor first — Φ(1.645) = 0.95 on each cohort by construction — then harvest speed: the tight cohort’s buffer 1.10 → 0.36 d, the wide cohort’s 1.10 → 2.63 d, slower on purpose. Result: +32 points of fast-promise share at exactly 95.0% on the model; no cohort subsidizes another.

Land this number: 95.0% on every cohort; wide-cohort buffer 2.63 d. · **Pivot to NACF:** The NACF promise is OTIF: protect the floor per lane, not per average. · **Do NOT say:** Do not say $13.3M a year as fact — say the model, in the same breath.

Q4 **Tell me about a time you set a high bar on how a change rolled out.** INSIST ON THE HIGHEST STANDARDS

Open (first two sentences): Nothing I designed went live without four consecutive shadow weeks, a promotion bar published before week one and a rollback kept warm.

STAR (≈90 s): Situation: padding fails silently and cutting fails loudly, so every promise system drifts slow. Task: roll out a tighter promise without a loud failure. Action: shadow mode — the challenger computed and logged per order, never displayed — promoted only if would-be accuracy held the floor on logged live orders with no rise in contact signals; and the Q4 drill showed a frozen summer dial printing 91.9%, so k is re-solved and published in October. Result: a governance instrument the marketplace's business owner — not data science — owns.

Land this number: 4 shadow weeks; Q4 σ × 1.45 → 91.9%. · **Pivot to NACF:** Any NACF promise change shadows a peak before it displays. · **Do NOT say:** Do not say the shadow ran — it is the design in the case.

SAME STORY, THREE ANGLES NEW — THREE DIFFERENT OPENERS, HEADLINE METRICS AND LPS FROM THE SAME FACTS

(I) DATA / ANALYTICAL

LP: Dive Deep

Open: "The headline was 95.8% and the policy was broken twice."

Headline metric: Φ(5.0) vs Φ(0.69) = 75.4%

- Flat 1.10 d = 5.0σ on one cohort, 0.69σ on another.
- Price of the floor on the wide cohort: +0.50 d for 97.5%.
- σ-estimation: ≈ 584 orders per cohort-window to hold within half a point.
- All model figures.

(II) CONFLICT / INFLUENCE / BACKBONE

LP: Have Backbone; Invent and Simplify

Open: "Data science wanted more model; I recommended one dial first."

Headline metric: +32 pts at 95.0%; D at 97.8% shown, never claimed

- The "no" was a priced row in the table.
- D ≈ +$20M/yr rides on a $12 breach cost I cannot observe.
- B holds a floor I can defend.
- One dial, owner named.

(III) FAILURE — LEARNING — WHAT I WOULD DO DIFFERENTLY

LP: Learn and Be Curious; Are Right, A Lot

Open: "A frozen dial broke the floor in the Q4 drill — 91.9%."

Headline metric: Q4 σ × 1.45 → 91.9%

- Re-solve k per regime, published in October.
- Normal errors understate the 99% dial; the empirical quantile fixes it.
- No production dollar — design case.
- VERIFY-WITH-RAJESH any failure beyond the drill is not in the record.

TRAP DRILLS NEW — THE THREE NASTIEST FOLLOW-UPS A STATISTICALLY RIGOROUS INTERVIEWER THROWS

T1 **"Your σ is estimated. How many orders per cohort before the 95% floor is safe?"**

The numbers: SE(σ̂) = 1 ÷ √(2(n−1)): n = 100 → 7.1% → realised 93.8%; n = 1,000 → 94.6%; ≥ 94.5% at a one-SE miss needs n ≈ 584.

Say exactly: "With a hundred orders a cohort, a σ one standard error low delivers about 94 percent against the 95 floor; to stay within half a point at a one-SE miss you need roughly 584 orders per cohort-window — trivial at a million orders a week, so the real risk is regime change, not estimation."

T2 **"Real transit errors are heavy-tailed. Does b = 1.645σ still hold 95%?"**

The numbers: Student-t_5 scaled to unit variance: 95% quantile 1.561σ (normal dial delivers 95.6%); 99% quantile 2.607σ (normal dial delivers 98.5%).

Say exactly: "At the 95 percent floor the normal dial is slightly conservative on heavy tails — it delivers about 95.6 — but at 99 it would fall to about 98.5, so production uses the empirical quantile and I treat the normal rule as the whiteboard version."

T3 **"Policy D is worth $20M a year. Why didn't you ship it?"**

The numbers: B: +$255K/wk × 52 = $13.3M/yr at a 95% floor. D: ($6.07M − $5.69M) × 52 = $19.8M/yr at 97.8% — on a $12 breach cost vs $6.50 margin, both model assumptions; at $6 the optimum falls toward the 95% floor.

Say exactly: "Policy D is the priced governance decision I handed to the marketplace's finance partner — it rests on a twelve-dollar breach cost nobody can observe; B holds a floor I can defend and is auditable, so I recommended B first and showed D without ever claiming it."

S20 — DESIGN CASE · Walmart Marketplace pre-purchase delivery — the weekly business review for pre-purchase delivery experience: 7 outputs over 10 inputs, factor math that names the owner in minutes, and an Andon that cuts detection-to-action from ~30 days to under 24 hours (design case) NEW

DESIGN CASE — not a delivered result. Built from my own interview-prep materials for a Walmart Marketplace pre-purchase delivery-experience role (requisition R-2596147: war book, Tech Ops WBR deep-dive and an Excel Solver model marked “ILLUSTRATIVE interview model · do not quote $ as a Walmart actual”, Aug–Sep 2026). No client engaged me, nothing was deployed, and every number below is prefixed “in the model.” Voice: “I designed / in the model / here is how I would run it.” **Lived record for this theme — Apple F4 (Elementum, record):** I replaced carrier-brochure lead times with measured transit distributions on 200 lanes, set the promise at the 99th percentile per lane, held 99% lead-time accuracy, and freed 580,000 units / about $1.5M of inventory carrying cost; the drift flag and refresh cadence kept the distributions honest. If asked “did this ship?” say: “No — this is a design case I worked through; the lived version of promise-at-the-tail is my 200-lane program.”

LPs this story serves here: Dive Deep (primary — factor math, the aggregate trap) · Ownership (one owner per output) · Invent and Simplify (7 outputs, 10 inputs, one joint headline) · Bias for Action (the Andon)
Process family: Plan / Deliver seam — metric architecture and control loop for the pre-purchase promise (Walmart Marketplace; role R-2596147)

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH NEW

- **Dive Deep** — I decomposed accuracy into O1 ≈ I3 × I4 × Φ(b/σ) = 0.97 × 0.985 × 0.996 ≈ 95.2% so a red week names its factor — a regional carrier miss (97% national, 82% in the Southeast) was attributed in minutes.
- **Ownership** — Promise accuracy was owned by a committee, so by nobody between Tuesdays; every output now has one named owner and every input a roll-up and an owner.
- **Invent and Simplify** — Seven outputs over ten inputs and one joint headline, Promise Yield = fast share × accuracy; “two dashboards is zero dashboards” is a written rule.
- **Bias for Action** — The Andon — a 7-day control chart per seller-lane cell, act within 24 hours — replaces a 30-day rolling window that let a degrading cell burn customers for weeks.

Honesty label. A design case, not a client design case: I worked it through for a Walmart Marketplace pre-purchase delivery-experience role. I designed the weekly business review on paper — the metric architecture, the decomposition math, the thresholds and the control loop — on my own sample weeks (Wk 28–33, illustrative). Nothing was stood up; in the design, the marketplace's engineering would build the pipelines and dashboards. I never claim a production output metric moved. The production-record version of this muscle is S11 (Flexport WBR, record) and the lived record for a promise built at the tail is Apple F4; I keep all three separate.

60-SECOND PITCH

"**Situation.** A marketplace client whose delivery promise was owned by a committee: data science owned the model, engineering the engine, seller ops the handling, carrier programs the lanes — and the one number the customer feels, promise accuracy, was owned by nobody between Tuesdays. The scorecards ran on 30-day rolling windows, so a degrading seller or carrier did weeks of customer damage before any floor bit, and a red week was a blame negotiation. **Task.** Design and stand up the weekly business review for the pre-purchase delivery experience — outputs a customer feels, input levers a named owner can turn, and the math that connects them — plus a control loop faster than the 30-day clock. **Action.** Discovery: one glossary, one event source, audited denominators. Plan & Design: seven output metrics over ten input levers, each input with a roll-up to the output it drives and a named owner; the factorization — accuracy ≈ seller-ships-in-window × carrier-meets-transit × Φ(buffer/σ) — as the decomposition; red/green at ±5% relative week-over-week with hard reds on policy floors. Build & Test: the sample-week proof — 0.97 × 0.985 × 0.996 ≈ 95.2% — and the drill: a regional carrier miss (97% nationally, 82% in the Southeast) decomposed to its factor in minutes. Cutover: Monday data freeze, Tuesday review, reds pre-wired with cause, owner, date. Hypercare: mix-adjusted twins next to every raw output, and the Andon — a 7-day control chart per seller-lane cell, act within 24 hours. **Result.** Primary metric (in the model): red-week attribution — **a blame negotiation → minutes, by factor math**; detection-to-action 30 days → under 24 hours by design; one joint headline, Promise Yield = fast share × accuracy, baseline 41.5% on the docs' sample. The only dollar is modeled: about $580K per caught degradation episode, and I say 'modeled' in the same breath."

20-SECOND VERSION NEW

The delivery promise was owned by a committee and scored on a 30-day window; I designed the weekly review — seven outputs over ten owned inputs, the factor identity that names the red, and an Andon that acts in under 24 hours — proven on sample data; the only dollar is modeled, about $0.58M per caught episode.

NACF BRIDGE — ONE SENTENCE

The NACF version is INV-E's OTIF chain: ship-in-window × carrier-meets-transit × buffer-absorbs-residual — a weekly review where every red names a factor and an owner.

SITUATION / TASK — WHERE IT OCCURRED, WHEN IT HAPPENED, WHY IT IS IMPORTANT

S — The same design case — Walmart Marketplace's seller-fulfilled delivery program, pre-purchase side. The promise the customer sees decomposes across three parties: the seller ships in a window, a carrier meets a transit time, a model plus a buffer absorbs the residual. The operating problem was measurement and ownership, not effort: promise accuracy, on-time delivery and late shipment lived on 30-day rolling windows that smear a step change into a slow drift; aggregate metrics hid the variance (a carrier can print 97% nationally while running 82% in the Southeast after a hub consolidation — the case's own worked example); three teams kept three clocks (order date, ship date, promise date); and when a week went red, the review discovered it live and negotiated blame instead of reading a decomposition.

T — Design the weekly business review for the pre-purchase delivery experience and lead the program that stood it up: the output metrics a customer feels, the input levers a named owner can turn this week, the math that connects them, the thresholds, and a control loop faster than the 30-day scorecard — then hand it to owners and leave.

Why it mattered: an output metric owned by a committee is owned by nobody between Tuesdays, and a 30-day window means a degrading cell burns customers for weeks before policy floors bite — enforcement lag was a named strategic issue in the case materials. Left unfixed: reds without owners, action items that age into a diary, mix-shift illusions celebrated as wins (portfolio accuracy improving while every cohort degrades, because volume shifted to easy metro lanes), and the speed-versus-accuracy trade argued as theology because nobody priced a breach.

The metrics on the table, with their baselines: red-week attribution time — days of cross-team negotiation (baseline condition); detection-to-action on a degrading cell — up to ~30 days on the rolling scorecard; output ownership —

committee; the joint headline — none (fast share and accuracy lived on separate lines with separate owners, tradeable against each other invisibly); the docs' sample baseline for that joint number: fast share 43.6% × accuracy 95.2% ≈ 41.5% Promise Yield.

ACTION — WHAT I PERSONALLY OWNED, HOW I DID IT, WHO ELSE WAS INVOLVED

A — Five gated phases (the metric definitions, formulas, thresholds and the Andon parameters are the design case's design record; the sample numbers are the docs' own illustrative set — six weeks of sample data proved the mechanics before any live line):

- **Discovery** — one glossary: every metric got one definition, one owner, one grain, one date basis (order date for operating cohorts; the 30-day windows kept only for seller-facing consequences); audited the denominators (cancelled orders quietly leaving the OTD base, suppressed listings leaving penetration). *Exit bar:* three teams' three clocks reconciled to one event source; no metric without a named definition owner.
- **Plan & Design** — the architecture: seven outputs (promise accuracy ≥95%, on-time delivery ≥90% policy floor, fast-promise penetration +2 pts/qtr, late shipment ≤5%, cancellation ≤2%, WISMO contacts −10% QoQ, A/B-measured conversion lift) over ten input levers (SSS share of GMV, ML-recommended handling coverage, seller handling adherence, carrier lane SLA adherence, transit-model error and freshness, buffer calibration, inventory-feed accuracy, eligibility coverage, engine latency/cache, onboarding throughput + 30-day retention) — every input carrying a roll-up to the outputs it drives and a named owner; red/green at ±5% relative week-over-week, hard reds on the policy floors regardless of trend; one joint headline, Promise Yield = fast share × accuracy. *Exit bar:* every output decomposable into named inputs with owners; definitions frozen in writing.
- **Build & Test** — the marketplace's engineering built the datasets and dashboard; I owned the proof on sample data: the factor identity (accuracy ≈ I3 × I4 × Φ(b/σ)) computed live — 0.97 × 0.985 × 0.996 ≈ 95.2% — then the drill: drop the Southeast carrier cell to 82% on a tenth of volume and watch the decomposition name the factor and the owner in minutes. *Exit bar:* the six-step loop (measure → variance → decompose → root-cause → act → verify) executed end-to-end on sample weeks; a red that arrives without cause, owner and date counted as a process miss.
- **Cutover / Go-Live (design)** — the operating rhythm: Monday data freeze on the Mon–Sun week, Tuesday review, pod leads pre-wire reds before the room; the action log with owner, date and visible ageing; "the meeting decides; it never discovers." *Exit bar:* two consecutive sample-cycle reviews run entirely pre-wired; the output block and the action log assigned to one named owner.
- **Hypercare / Close** — the honesty layer and the control loop: mix-adjusted twins printed next to every raw output (fixed base-quarter cohort weights; the delta *is* the mix effect) so Simpson's paradox can't celebrate volume migrating to easy lanes; and the Andon — a 7-day EWMA/CUSUM control chart per seller-lane cell, tripwire at a sustained 2× baseline breach rate with n ≥ 30 orders, action within 24 hours (widen that cell's buffer or pull its fast badge), auto-restore on recovery, designed false-trip rate under 5%. *Exit bar:* the verify step closing the loop — if an input moved and its output didn't, the roll-up hypothesis is declared wrong and re-examined, in writing.

The marketplace's engineering built every pipeline and surface; data science owned the models behind the transit and buffer lines; seller ops and carrier programs owned their levers. Mine: the glossary and denominator audit, the output/input architecture and the roll-up map, the factorization as the decomposition instrument, the thresholds and floors, the six-step loop, the mix-adjusted twins, the Andon design and its parameters, and the handoff that left the output block owned by a person, not a committee.

The obstacle was that every team already had a dashboard and nobody wanted a new clock — overcome by making the review cheaper than the status quo: the decomposition turned the worst meeting of the week (the blame negotiation) into a five-minute read, and the pre-wire rule moved the argument out of the room. The decision I challenged: the program wanted more metrics; I held the board to seven outputs and ten inputs — a metric nobody owns or acts on came off the board, and "two dashboards is zero dashboards" went into the design note as a rule, not a preference.

RESULTS — HOW SUCCESS WAS MEASURED: $ · # · % · TIME · CUSTOMER · QUALITY

R — Primary metric (in the model): red-week attribution — from a cross-team blame negotiation to minutes, by factor math (proven on the sample-data drill); detection-to-action on a degrading cell — ~30 days → under 24 hours by design (the Andon). The only dollar is modeled: ≈$0.58M per caught episode.

- **$** — ≈$0.58M per caught degradation episode, modeled: a Southeast-type carrier miss costs ≈$192K/week in excess breaches; caught and corrected in ≤1 week instead of ~4, three weeks × $192K ≈ $576K avoided (inputs below; the $12 breach cost is the model's stated assumption). No annual figure — episode frequency is the marketplace's data, and I won't invent it.
- **#** — 7 output metrics over 10 input levers, every input with a roll-up and a named owner; 1 joint headline (Promise Yield); 1 action log; 6 sample weeks proving the mechanics (design-case record (not delivered) on the docs' illustrative set).
- **%** — Promise Yield baseline 43.6% × 95.2% ≈ 41.5% on the docs' sample, four-quarter design target 50%; red/green at ±5% relative WoW; hard reds on the floors (OTD < 90%, late shipment > 5%, cancellation > 2%); Andon false-trip design bar < 5%.
- **Time** — Red-week attribution: days → minutes (the factor math); detection-to-action: ~30 days of rolling-window lag → < 24 hours from a sustained signal (designed); Monday freeze → Tuesday review, reds pre-wired before the room.
- **Customer** — The Andon protects customers at the grain where variance lives (the seller-lane cell) instead of letting a degrading cell burn them for a month; WISMO contacts sit on the output board so promise failures are read in customer contacts, not just percentages.
- **Quality** — Mix-adjusted twins next to every raw output (the mix effect printed as its own line); denominators audited; the verify step that falsifies the lever map itself when an input moves and its output doesn't — the mechanism that keeps the instrument honest after I leave.

Against the goal stated above: one owner of the output block instead of a committee, a decomposition that names the factor and the owner in minutes, a control loop 30× faster than the scorecard clock, and a joint headline that makes the speed-accuracy trade un-gameable at the KPI layer. The trade was explicit: seller-facing consequences stayed on the fair 30-day window — the Andon acts on cells and badges, never on scorecards — stability for sellers, speed for customers.

L6 LEVEL EVIDENCE — what the interviewer pattern-matches against the Amazon L6 functional rubric

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	No agreed glossary or owner for the promise output; I defined one definition, one owner, one grain, one date basis per metric.
Scope & influence	Data science, engineering, seller ops and carrier programs — none reporting to me; every team already had a dashboard and nobody wanted a new clock.
Execution	Metric architecture, decomposition proof, red-week drill, Monday freeze / Tuesday review, Andon design and hypercare rule.
Impact	Red-week attribution days → minutes (drill); detection-to-action ~30 days → under 24 hours by design; no production metric claimed.
Process improvement	A standing review with pre-wired reds, mix-adjusted twins and an action log with owners and dates.
Complexity	Aggregates hiding cells; mix-shift illusions; rolling-window lag; a gameable pair of metrics.
Root cause	The root cause was ownership and clocks, not data: three teams on three clocks and no joint metric.

THE FIVE FACETS NEW — data analysis · solution design · math & data logic · implementation · probe questions; each labeled so the interviewer can see all five are present

1 · Data analysis	Data: the case's sample set — six weeks, seven outputs, ten inputs; fast share 43.6% × accuracy 95.2%; carrier 97% national vs 82% Southeast. Revealed: the aggregate hid the cell; the rolling window hid the lag.

2 · Solution design	Options: more metrics · fewer, owned metrics · 30-day windows · a 7-day cell chart. Chosen: 7 outputs / 10 inputs / one joint headline / Andon per seller-lane cell.
3 · Math & data logic	Math: O1 ≈ I3 × I4 × Φ(b/σ) = 0.9516; episode: I4′ = 0.9685 → O1′ = 93.6%; $192K/wk × 3 wks = $576K; Andon binomial false-trip arithmetic; mix-shift example; Promise Yield gaming test.
4 · Implementation	Implementation: glossary → architecture → sample-data proof → Monday freeze, Tuesday review → pre-wired reds → Andon with auto-restore → mix-adjusted twins.
5 · Probe questions	Probe questions: Andon false-trip rate · mix-shift · whether the joint headline can be gamed · any production claim — see Trap Drills.

PROBING — CHALLENGE Q&A (MASTER RECORD) PLUS THE STATISTICAL QUESTIONS

***Challenge* — Why did you choose this story to illustrate Insist on the Highest Standards?**

Because the standards here are numbers with teeth, published in advance: hard reds on policy floors regardless of trend, a pre-wire rule that makes an unexplained red a process miss, and an Andon whose tripwire, sample floor and false-trip bar were written before the first live week. A standard that can't stop a program is decoration.

***Probing* — Why did you choose to focus on these results? What other results were important?**

Attribution speed and detection speed lead because they are what a review is for — a WBR that can't say which lever moved is a viewing, not a review. Also important: the joint headline (Promise Yield) that stops the two factor teams trading against each other invisibly, and the mix-adjusted twins that keep a growth quarter from flattering the numbers.

***Probing* — You mentioned dollars — what percentage change is that year over year?**

None claimed — the ≈$0.58M is per caught episode, modeled from the sample-data drill, and I don't multiply it by an invented episode frequency. The year-over-year story here is mechanism speed: 30 days of enforcement lag to under 24 hours.

***Probing* — I'm concerned your baseline Promise Yield is from sample data — tell me more.**

Correct, and I say so: 43.6% × 95.2% ≈ 41.5% is my case materials' own illustrative six-week set, used to prove the mechanics before live lines existed. The design target — 50% in four quarters — is a target on the real book, and the first live job is re-baselining it.

***Challenge* — What were the lessons learned? What would you have done differently?**

Lesson: the decomposition is the peace treaty — attribution math is what turns a blame negotiation into a five-minute read. Differently: I'd have run the denominator audit in week one rather than mid-design; two of the "metrics" we inherited changed meaning once cancelled orders stopped quietly leaving the base.

***Challenge* — How would you implement this at Amazon?**

This is Amazon's own grammar — input levers under output metrics, reds pre-wired with an ask, COE-style mechanism fixes — so the transplant is the control loop: factor math on the promise seam, mix-adjusted twins beside raw outputs, and cell-grain Andon where a 30-day window is too slow for the customer.

***Challenge* — How did these results compare to your actual goals?**

The signed goals were one owner of the output block, decomposition in minutes, and a sub-24-hour control loop — all three specified as the standing instrument, proven on six sample weeks, with the verify step written so the lever map itself can be falsified and corrected.

PHASE DEEP-PROBE BANK — Q&A (12). *Answer the phase asked, then stop.*

Discovery — How did you know discovery was done?

When three teams' three clocks — order date, ship date, promise date — reconciled to one event source, and every metric on the inherited boards had exactly one definition owner or was struck. The exit memo listed the denominator findings with owners, not hopes.

What did the denominator audit find?

The classic games, running unmalevolently: cancelled orders quietly leaving the on-time base, suppressed listings leaving the penetration base. Neither was fraud — both were defaults nobody owned. The rule that fixed it: metric governance audits denominators, not just numerators.

Plan & Design — Why seven outputs and ten inputs, not more?

Because a board nobody can hold in their head is a board nobody reads. The cut rule was ruthless: an input had to be provably upstream of an output, turnable this week, and owned by a name — a metric nobody owns or acts on came off. Everything else lives in drill-down, not on the board.

Why is Promise Yield the headline instead of accuracy?

Because either factor alone is gameable: chase accuracy and you pad buffers until every promise is slow and safe; chase penetration and you shave buffers until promises are fast and broken. The product punishes both games — and the board still decomposes it one line below, because a composite that can't be decomposed is a hiding place.

Why keep the 30-day window at all?

Fairness. A seller consequence — a scorecard, a suspension — deserves a stable clock that one bad day can't trip. The design splits the clocks: 30-day for consequences, 7-day panels for operations, and the Andon acting on cells and badges in hours. Each clock does the job it's fair at.

Build & Test — Walk me through the sample-week factor proof.

Seller-ships-in-window 0.97, carrier-meets-transit 0.985, buffer absorption $\Phi(b/\sigma)$ 0.996 — product 95.2%, matching the sample week's printed accuracy. Then the drill: Southeast carrier adherence to 82% on 10% of volume → the carrier factor falls to 0.9685, accuracy to 93.6%, and the week-over-week factor deltas name the carrier PM in one read.

How did you test the Andon's false-trip rate?

On the sample set: replayed stable cells through the EWMA/CUSUM chart and counted trips. The $n \geq 30$ floor and the sustained-signal requirement (CUSUM, not single-week thresholds) are what hold designed false trips under 5% — a noise-tripped Andon punishes small sellers and kills the mechanism's legitimacy.

Cutover — What does "pre-wired" mean mechanically?

Before Tuesday, every red line arrives with its factor decomposition, the named input that moved, the owner, and a dated action. The meeting's job is to decide on the ask — never to discover the cause. A red discovered live is logged as a process miss on the review itself.

Who could stop what?

Hard reds on policy floors stop expansion into the affected cohort automatically — eligibility growth doesn't board on a floor breach. The Andon stops a cell's fast badge without waiting for a meeting. And the output-block owner can hold any launch that would change a metric's meaning mid-flight.

Hypercare — What are mix-adjusted twins and why print both?

Every output twice: raw, and re-weighted on fixed base-quarter cohort weights. The delta between them is the mix effect, printed as its own line — so the room stops celebrating "improvements" that are volume migrating to easy metro lanes, and stops flogging teams for "degradation" that is growth into hard geographies. Re-based quarterly, by written policy.

What does the verify step do when an input moved and the output didn't?

It declares the roll-up hypothesis wrong, in writing, and re-examines the lever map — that is how the map stays honest. A WBR that never falsifies its own causal claims degrades into numerology with owners.

Cross-phase — What did you refuse?

A bigger board (metrics without owners), a faster clock for seller consequences (unfair), an annual dollar claim for the Andon (no episode-frequency basis), and running the first live weeks myself — the instrument had to be owned by the marketplace's named owner from day one, or it would have stayed mine and died when I left.

Analytics — What is the false-trip rate of an Andon that fires on "7-day breach rate ≥ 2× baseline, n ≥ 30"?

The record carries EWMA/CUSUM parameters and a false-trip design bar under 5%; the binomial analog shows why n ≥ 30 alone cannot meet it. Baseline breach rate 5% (the 95% floor): at n = 30 a "2×" trigger is 3 breaches, which a healthy cell produces 18.8% of weeks and catches a true 2× cell only 59% of weeks; the smallest trigger under 5% at n = 30 is 5 breaches (3.3× baseline, false trips 1.6%). At n = 100, "2×" is 10 breaches: false trips 2.8%, power 55%. A 2× rule is only clean from about n = 103; below that, "sustained" — several consecutive days — has to do the work.
VERIFY-WITH-RAJESH the exact EWMA/CUSUM parameters.

Analytics — Show me a mix-shift illusion.

Two cohorts, metro and rural. Before: 97% and 88% at a 50/50 mix = 92.5%. After: each cohort degrades a point — 96% and 87% — but volume shifts to 70% metro: 93.30%. The raw number rises 0.80 points while every cohort falls; at the old mix the same week is 91.5%, down 1.0. That is the mix-adjusted twin, printed beside every raw output. Illustrative numbers.

Analytics — Can Promise Yield be gamed?

Yes, if it is the only constraint. Yield = fast share × accuracy = 0.436 × 0.952 = 41.5%. Push fast share up 2 points and let accuracy fall to 94.2% and yield rises to 43.0% — a trade the product rewards and the customer pays for. That is why the floors are hard reds regardless of trend (accuracy ≥ 95%), and why yield is a headline, not a target.

STATISTICAL SPINE — ANDON FALSE-TRIP ARITHMETIC, MIX-SHIFT, HEADLINE GAMING (EXTRA TABLE)

The record: 7 outputs over 10 inputs; the factor identity; a 7-day Andon with false-trip design bar under 5% and EWMA/CUSUM parameters; mix-adjusted twins; hard floors. The table below is my binomial and mix arithmetic on illustrative cells — it explains the design, it is not a production measurement.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Healthy-cell breach rate	$p_0 = 1 - 0.95 = 5\%$	accuracy floor 95% (in the model)	$p_0 = 5\%$
2	"2× baseline" at n = 30	trigger c = 2 × 0.05 × 30 = 3 breaches; false trips P(X ≥ 3 | 30, 0.05) = 18.8%; power at p = 10%: 59%	binomial analog of the 7-day cell chart	false trips 18.8% — over the 5% bar
3	Smallest trigger under 5% at n = 30	c = 5 breaches = 3.3× baseline; false trips 1.6%; power at 10%: 18%	same method	5/30
4	"2×" at n = 100	c = 10; false trips 2.8%; power at 10%: 55%	same method	false trips 2.8% — under the bar
5	Smallest trigger under 5% at n = 300	c = 22 = 1.47× baseline; false trips 4.86%	same method	1.47× suffices
6	Orders for a clean "2×" rule	$n = 0.0475 \times (2.33 \div 0.05)^2 = 103$	$p_0(1 - p_0) = 0.0475$; 2.33σ margin to 10%	≈ 103 orders per cell-week
7	Mix-shift: before	0.5 × 97% + 0.5 × 88% = 92.5%	illustrative cohorts	92.5%
8	Mix-shift: after, raw	0.7 × 96% + 0.3 × 87% = 93.30%	both cohorts −1 pt; mix shifts to metro	93.30% (up 0.80)
9	Mix-shift: after, old mix	0.5 × 96% + 0.5 × 87% = 91.5%	mix-adjusted twin	91.5% (down 1.0)

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
10	Promise Yield gaming	`0.436 × 0.952 = 41.5%; 0.456 × 0.942 = 43.0%`	fast share +2 pts, accuracy −1 pt (illustrative)	yield up 1.4 pts while accuracy falls

BUSINESS IMPACT MODEL — KPI TREE, NUMBERS, THE MATH

```
Customer promise kept + operating speed (primary outcome)
+- Attribution speed (time) -> days of negotiation -> minutes
|    O1 ≈ I3 x I4 x Phi(b/sigma): the biggest factor WoW delta names the owner
+- Detection-to-action (time) -> ~30d rolling lag -> <24h (Andon per cell)
|    (loop) late detection -> weeks of excess breaches -> WISMO + trust decay
+- Excess-breach cost per episode ($) -> modeled below
+- Gaming resistance -> Promise Yield = fast share x accuracy (one headline)
+- Honesty -> mix-adjusted twins; audited denominators; verify step
     falsifies the lever map itself
```

DRIVER	BASELINE	AFTER	$	BASIS
Red-week attribution	cross-team negotiation, days	factor math, minutes	—	design-case record (not delivered) (sample-data drill)
Detection-to-action on a degrading cell	up to ~30 days	< 24 h from sustained signal	—	designed (Andon: EWMA/CUSUM, 2× baseline, n ≥ 30)
Excess breaches during one Southeast-type episode	≈16,000/wk for ~4 wks	≤1 wk	≈$0.58M avoided per episode	modeled ($12 breach assumption; illustrative book)
Joint headline	none (two gameable lines)	Promise Yield 41.5% (sample) → 50% 4-qtr target	—	in the model (sample set); target is design
Annual Andon value	not claimed — episode frequency is the marketplace's data		—	deliberately uninvented

If challenged. *"You never ran this live."* — "Correct, and I say so — the design case produced, on paper, the instrument proven on six sample weeks; the marketplace's owners run it. The production record for running this cadence weekly for a year is S11, with record numbers." *"The $580K rests on a $12 breach cost."* — "The $12 is the model's stated bundle — contact, refund risk, trust decay — put on the table so Finance could attack it. At $6 the episode is still ≈$290K; the mechanism argument — act in hours, not weeks — survives any price." *"Isn't a sub-24-hour Andon rash?"* — "It acts on a cell's buffer or badge — reversible in one flag, auto-restored on recovery — never on a seller's scorecard. The n ≥ 30 floor and the sustained-signal test are the guards; the 30-day window stays for consequences."

THE MATH — STEP-BY-STEP DERIVATION

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	The accuracy identity	`O1 ≈ I3 × I4 × Φ(b/σ) — seller ships in window × carrier meets transit × buffer absorbs the residual`	in the model factorization; three factors, three owners	every breach belongs to exactly one factor
2	Healthy sample week	`O1 = 0.97 × 0.985 × 0.996 = 0.9516 ≈ 95.2%`	I3 = 0.97, I4 = 0.985, Φ = 0.996 (docs' illustrative sample)	95.2% — matches the sample print

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
3	The aggregate trap	`carrier prints 97% nationally while one region runs 82%`	Southeast after a hub consolidation (in the model example)	the average hides the cell
4	The rolling-window lag	`a step change entering a 30-day window moves the average ≈1/30 per day`	30-day scorecard mechanics (in the model issue)	weeks before a floor bites — enforcement lag
5	The gameable pair	`fast share 43.6% and accuracy 95.2% on separate lines, separate owners`	docs' sample; either can be juiced by bleeding the other	no joint headline
6	Baseline joint number	`Promise Yield = 0.436 × 0.952 = 0.415`	rows 2, 5 (docs' sample)	≈ 41.5%

Table 2 — the fix: step by step, values substituted (the red-week drill).

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	The episode	`Southeast cell: carrier adherence 0.985 → 0.82 on w = 10% of volume`	82% is the docs' example; the 10% weight is illustrative	one regional carrier miss
2	New carrier factor	`I4' = 0.90 × 0.985 + 0.10 × 0.82 = 0.8865 + 0.082 = 0.9685`	volume-weighted blend (illustrative)	I4: 0.985 → 0.9685 (−1.7%)
3	New accuracy	`O1' = 0.97 × 0.9685 × 0.996 = 0.9357 ≈ 93.6%`	rows 1–2; other factors unchanged	95.2% → 93.6% — a red week
4	The attribution read	`WoW deltas: I3 0.0% · I4 −1.7% · Φ 0.0%`	computed per factor (the decomposition)	the red names I4 and the carrier PM — in minutes
5	Segmentation	`factor red isolated to one region ⇒ C-family cause, not model or seller`	lane/cohort cut of I4 (design)	cause class identified before the meeting
6	The Andon trigger	`cell 7-day breach rate sustained ≥ 2 × baseline, n ≥ 30 ⇒ act < 24 h`	EWMA/CUSUM parameters (in the model design)	buffer widened or badge pulled on the cell, same day
7	Auto-restore	`control chart recovers ⇒ badge/buffer restored, no meeting needed`	design	surgical, reversible, seller-fair

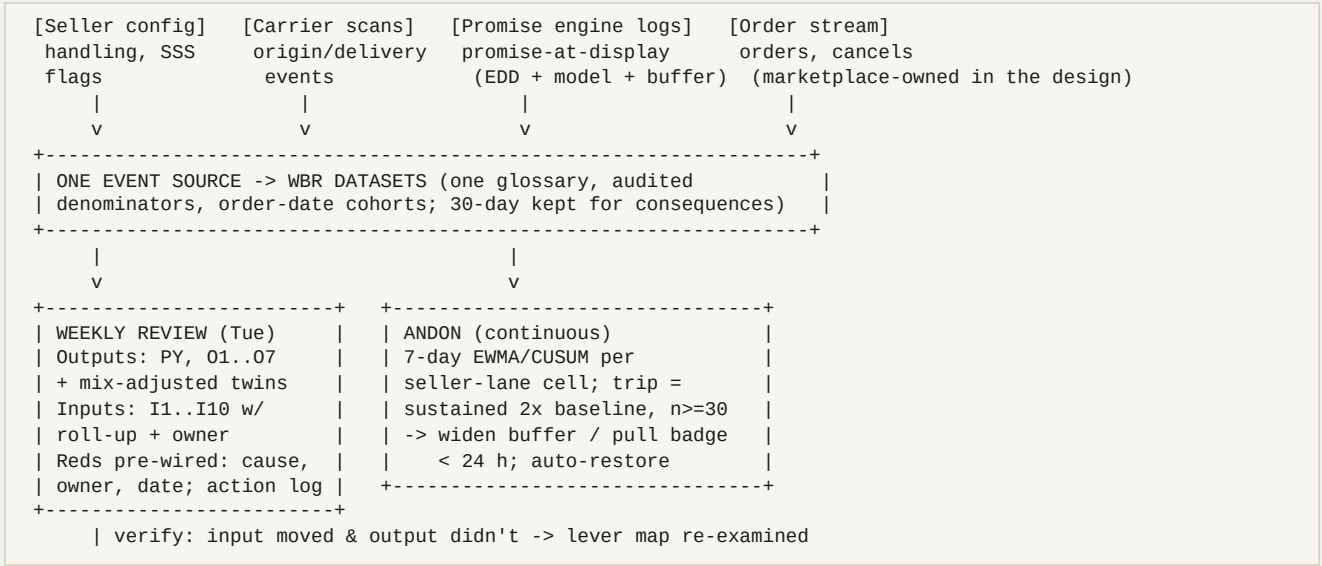

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Red-week attribution time	days (blame negotiation)	minutes (factor math)	design-case record (not delivered), proven on the drill
2	Detection-to-action, degrading cell	up to ~30 days	< 24 h from sustained signal	designed (Andon)
3	Output ownership	committee	one named owner of the output block + log	design-case record (not delivered)
4	Joint headline	none	Promise Yield, 41.5% sample baseline → 50% 4-qtr target	docs' sample; design target
5	Mix honesty	raw outputs only	mix-adjusted twin + mix line per output	design-case record (not delivered)

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Episode accuracy loss	`95.2% − 93.6% = 1.6 points`	Table 2 rows 2–3 (illustrative episode)	1.6 pts of excess breaches
2	Excess breaches per week	`1,000,000 × 1.6% = 16,000`	~1M orders/wk illustrative book	≈16,000 breaches/wk
3	Cost per breach	`$12, taken as stated`	the model's assumption: contact + refund risk + trust decay (in the model)	$12 each
4	Excess cost per week	`16,000 × $12 = $192,000`	rows 2 × 3 (modeled)	≈$192K/wk
5	Detection advantage	`~4 weeks (rolling-window era) − 1 week (Andon era) = 3 weeks`	row 4 of Table 1; Andon design	3 weeks earlier action
6	Avoided per episode	`$192,000 × 3 = $576,000`	rows 4 × 5 (modeled)	≈$0.58M per caught episode
7	Annual total	`not computed — $576,000 × (episodes/yr) requires a frequency I don't have`	deliberately uninvented	per-episode only, labeled modeled

SOLUTION FLOW — THE SYSTEM & DATA MAP

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Breach cost (model assumption)	$6	$12	$18
Episode size (regional weight × adherence drop)	5% × −10 pts	10% × −16.5 pts	15% × −20 pts
Excess cost per week	≈$50K	≈$192K	≈$430K
Weeks of detection advantage	2	3	4
Avoided per caught episode	≈$0.1M	≈$0.58M	≈$1.7M

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

"What the design case produced, on paper, is an instrument: seven output metrics a customer feels over ten input levers with named owners, one joint headline — fast share times accuracy — and the factor math that attributes a red week to seller, carrier or model in minutes instead of a week of negotiation. The control loop went from a thirty-day rolling window to under twenty-four hours at the seller-lane cell. The one dollar I'll quote is modeled and I'll label it as I say it: a regional carrier degradation of the kind in the case materials costs about a hundred ninety thousand a week in excess breaches at the model's twelve-dollar breach cost, and catching it three weeks earlier is worth roughly five hundred eighty thousand per episode. I don't annualize it — the episode frequency is the marketplace's data, not mine."

BEHAVIORAL PACK NEW — FOUR QUESTIONS THIS STORY ANSWERS, FOUR SEPARATE 90-SECOND ANSWERS (EACH FROM A DIFFERENT MOMENT OF THE STORY)

Q1 **Tell me about a time you found the root cause of a problem everyone was arguing about.** DIVE DEEP

Open (first two sentences): Carrier on-time printed 97% nationally and the Southeast was at 82%. The review used to spend a week arguing about whose fault that was; the factor math named the cell in minutes.

STAR (≈90 s): Situation: promise accuracy was owned by a committee and a red week was a blame negotiation. Task: design a review where a red names its cause. Action: the identity accuracy ≈ seller ships in window × carrier meets transit × Φ(buffer ÷ σ) — 0.97 × 0.985 × 0.996 ≈ 95.2% — and the drill: drop the Southeast carrier cell to 82% on a tenth of volume and watch the decomposition: carrier factor 0.985 → 0.9685, accuracy 95.2% → 93.6%, the carrier factor named. Result: attribution in minutes on the sample data, with a named owner.

Land this number: 0.985 → 0.9685; 95.2% → 93.6%; attribution days → minutes. · **Pivot to NACF:** INV-E's OTIF chain is the same decomposition for NACF inbound. · **Do NOT say:** Do not say any production metric moved — the design case produced, on paper, the instrument and its sample-data proof.

Q2 **Tell me about a time you took ownership of something with no clear owner.** OWNERSHIP

Open (first two sentences): The one number the customer feels — promise accuracy — was owned by nobody between Tuesdays.

STAR (≈90 s): Situation: data science owned the model, engineering the engine, seller ops the handling, carrier programs the lanes. Task: a weekly review with one owner per output and a named owner per input. Action: one glossary — one definition, owner, grain and date basis per metric — seven outputs, ten inputs with roll-ups, red/green at ±5% relative week-over-week and hard reds on policy floors, reds pre-wired with cause, owner and date before the room. Result: the review became cheaper than the status quo — a five-minute read instead of the worst meeting of the week.

Land this number: 7 outputs · 10 inputs · every one with an owner. · **Pivot to NACF:** Every NACF review metric needs a definition owner and a grain. · **Do NOT say:** Do not say the marketplace adopted it in production.

Q3 **Tell me about a time you pared something down to make it work.** INVENT AND SIMPLIFY

Open (first two sentences): The program wanted more metrics. I held the board to seven outputs and ten inputs and wrote “two dashboards is zero dashboards” into the design note.

STAR (≈90 s): Situation: every team already had a dashboard and nobody wanted a new clock. Task: make the review cheaper than what it replaced. Action: a metric nobody owns or acts on comes off the board; one joint headline, Promise Yield = fast share × accuracy, 43.6% × 95.2% ≈ 41.5% on the docs' sample; mix-adjusted twins beside each raw output. Result: a board small enough to run in a meeting; four-quarter design target 50% for Promise Yield.

Land this number: 41.5% sample baseline → 50% design target. · **Pivot to NACF:** Same discipline for any placement scorecard: fewer owned metrics. · **Do NOT say:** Do not present the 50% as a result — it is a design target.

Q4 **Tell me about a time you built something to act faster than the process allowed.** BIAS FOR ACTION

Open (first two sentences): A 30-day rolling scorecard lets a degrading seller or carrier burn customers for weeks. I designed a control that acts in 24 hours.

STAR (≈90 s): Situation: a step change entering a 30-day window moves the average about 1/30 per day, so floors bit weeks late. Task: close the loop faster without a meeting. Action: the Andon — a 7-day control chart per seller-lane cell; sustained breach at ≥ 2× baseline with n ≥ 30 triggers a same-day action — widen the buffer or pull the badge — and auto-restores when the chart recovers. Result: detection-to-action designed from ~30 days to under 24 hours; ≈$0.58M per caught episode modeled.

Land this number: ~30 days → < 24 hours (design); ≈$0.58M per episode (modeled). · **Pivot to NACF:** NACF inbound: a per-vendor-lane control chart with an auto-restore beats a monthly scorecard. · **Do NOT say:** Do not annualize the $0.58M — episode frequency is the marketplace's data.

SAME STORY, THREE ANGLES NEW — THREE DIFFERENT OPENERS, HEADLINE METRICS AND LPS FROM THE SAME FACTS

(I) DATA / ANALYTICAL

LP: Dive Deep

Open: "The carrier was 97% nationally and 82% in one region — the average hid the cell."

Headline metric: accuracy 95.2% → 93.6% via one factor

- O1 ≈ I3 × I4 × Φ(b/σ).
- WoW deltas by factor: I4 −1.7%.
- Mix-adjusted twin: raw +0.8 pt, adjusted −1.0 pt.
- Andon false-trip arithmetic.

(II) CONFLICT / INFLUENCE / BACKBONE

LP: Have Backbone; Ownership

Open: "The program wanted more metrics; I held it to seven and ten."

Headline metric: 7 outputs / 10 inputs / 1 joint headline

- A metric nobody owns comes off the board.
- Hard floors regardless of trend.
- Reds pre-wired before the room.
- No production claim.

(III) FAILURE — LEARNING — WHAT I WOULD DO DIFFERENTLY

LP: Are Right, A Lot; Learn and Be Curious

Open: "A multiplicative headline can still be gamed."

Headline metric: yield 41.5% → 43.0% while accuracy falls to 94.2%

- The joint headline needs hard floors beside it.
- n ≥ 30 alone gives 19% false trips at 2×.
- This is a design case — nothing in production moved.
- VERIFY-WITH-RAJESH any live Andon results are not in the record.

TRAP DRILLS NEW — THE THREE NASTIEST FOLLOW-UPS A STATISTICALLY RIGOROUS INTERVIEWER THROWS

T1 **"Your Andon fires at 2× baseline with n ≥ 30. What is the false-trip rate?"**

The numbers: p_0 = 5%: n = 30, c = 3 → false trips 18.8%, power 59%; need c = 5 for < 5%; n = 100, c = 10 → 2.8%; clean 2× rule from n ≈ 103.

Say exactly: "On a single week at thirty orders a healthy cell trips about 19 percent of the time at two-times baseline and a true doubling is caught only about 59 percent — so the record's EWMA and "sustained" logic carries the false-trip bar under five percent; a clean two-times rule needs about 103 orders a cell-week."

T2 **"Raw accuracy improved. Is it improving?"**

The numbers: Before 0.5 × 97 + 0.5 × 88 = 92.5%; after 0.7 × 96 + 0.3 × 87 = 93.30%; at the old mix 91.5%.

Say exactly: "Not necessarily — in my example the raw number rises about 0.8 of a point while every cohort falls a point, because volume moved to the easy lanes; at the old mix it is down a full point. That is why a mix-adjusted twin prints beside every raw output."

T3 **"Promise Yield is fast share × accuracy. Can a team game it?"**

The numbers: 0.436 × 0.952 = 41.5%; fast share +2 pts, accuracy −1 pt → 0.456 × 0.942 = 43.0%.

Say exactly: "Yes, if it is the only constraint — two points of speed for one point of accuracy raises it from forty-one and a half to forty-three — so the accuracy floor is a hard red regardless of trend, and the yield is a headline, not a target."

S21 — DESIGN CASE · Walmart Marketplace pre-purchase delivery — the stalled managed-shipping program: an incentive diagnosis, an all-or-nothing insurance contract and a shadow gate — about $3.7M a year per ten points of enrolled GMV, modeled NEW

DESIGN CASE — not a delivered result. Built from my own interview-prep materials for a Walmart Marketplace pre-purchase delivery-experience role (requisition R-2596147: war book, Tech Ops WBR deep-dive and an Excel Solver model marked “ILLUSTRATIVE interview model · do not quote $ as a Walmart actual”, Aug–Sep 2026). No client engaged me, nothing was deployed, and every number below is prefixed “in the model.” Voice: “I designed / in the model / here is how I would run it.” **Lived record for this theme — Apple F4 (Elementum, record):** I replaced carrier-brochure lead times with measured transit distributions on 200 lanes, set the promise at the 99th percentile per lane, held 99% lead-time accuracy, and freed 580,000 units / about $1.5M of inventory carrying cost; the drift flag and refresh cadence kept the distributions honest. If asked “did this ship?” say: “No — this is a design case I worked through; the lived version of promise-at-the-tail is my 200-lane program.”

LPs this story serves here: Dive Deep (primary — adverse selection in declared handling) · Invent and Simplify (an all-or-nothing contract) · Earn Trust (I claim the contract, never the curve) · Insist on the Highest Standards (shadow gate and graduation criteria)
Process family: Deliver seam — seller-fulfilled delivery: transit settings, handling and the promise (Walmart Marketplace; role R-2596147)

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH NEW

- **Dive Deep** — I read the stall as adverse selection, not marketing: sellers declared one-day handling to win placement and hit it about 85% of the time — the miss became the marketplace’s broken promise.
- **Invent and Simplify** — I rebuilt the offer as one insurance contract — transit automation + observed handling + a participating label — with the benefit priced in the seller’s own dollars.
- **Earn Trust** — I claim the contract design and wave-one mechanics only — the adoption curve after wave one belongs to the marketplace — and I say “modeled” in the same breath as $3.7M.
- **Insist on the Highest Standards** — Shadow-run a seller’s orders under managed settings before flipping; a wave that fails a published criterion does not board the next cohort.

Honesty label. A design case, not a client design case: I worked it through for a Walmart Marketplace pre-purchase delivery role. The marketplace's "Simplified Shipping Settings" (SSS) lets it manage a seller's transit settings and absorb carrier-delay accountability; in my case materials adoption sits at roughly 38–42% of seller-fulfilled GMV (a prep estimate, not a Walmart actual). I designed the adoption program on paper: the incentive diagnosis, the insurance-contract offer, the wave mechanics and the measurement pair. Nothing was built or run — no wave boarded, no seller enrolled; I claim the contract design and the wave mechanics as a design, never an adoption curve.

60-SECOND PITCH

"**Situation.** A marketplace client owning the delivery promise on inventory in sellers' buildings. Its managed-shipping program — the marketplace picks the transit settings and absorbs carrier-delay accountability — had stalled at roughly 38 to 42 percent of seller-fulfilled GMV, so the majority of promise risk still rode on manual seller configuration. And that configuration was optimistic by construction: sellers declared one-day handling to win placement and hit it about 85 percent of the time — adverse selection, not bad luck; the miss became the marketplace's broken promise. **Task.** Lead the adoption-program design: diagnose why sellers refused, rebuild the offer, design the rollout and its gates, and leave the marketplace a measurement pair that can't be gamed. **Action.** Discovery: enrollment-funnel and refusal interviews — sellers were trading away control for a benefit that was real but unpriced and weakly communicated; an incentive-design problem, not a feature-marketing problem. Plan & Design: the offer rebuilt as an all-or-nothing insurance contract — transit automation plus observed handling plus a participating label, full bundle earns scorecard protection — with a personalized GMV-delta line in Seller Center making the benefit concrete in the seller's own dollars. Build & Test: shadow-run a seller's orders under managed settings before flipping, so day one is verified, not hoped. Cutover: waves behind published graduation criteria — a wave that fails one doesn't board the next cohort. Hypercare: the honest pair — activations per week *and* 30-day retention; enrollments without retention is churn wearing a growth costume. **Result.** Primary deliverable: the signed contract design and wave-one mechanics; the modeled economics — **about $3.7M a year per ten points of enrolled GMV** from handling-miss reduction alone — and I say 'modeled' in the same breath; the adoption curve after wave one belongs to the marketplace, not to my record."

20-SECOND VERSION NEW

The managed-shipping program stalled at ~38–42% of GMV because sellers traded control for an unpriced benefit; I rebuilt it as an all-or-nothing insurance contract with a shadow gate and published wave criteria — about $3.7M a year per ten points of enrolled GMV, modeled; the adoption curve is the marketplace’s.

NACF BRIDGE — ONE SENTENCE

The NACF analog is vendor-managed inbound: where a vendor’s declared lead time or handling is optimistic by incentive, I would move to observed performance and price the trade for the vendor.

SITUATION / TASK — WHERE IT OCCURRED, WHEN IT HAPPENED, WHY IT IS IMPORTANT

S — The same design case — Walmart Marketplace's seller-fulfilled program, adoption side. The structural fact: the marketplace underwrites the delivery promise, but the inputs that keep it — handling time, ship nodes, carrier choices — are configuration data that thousands of independent sellers set themselves, optimistically, and update rarely. The managed-settings program existed precisely to fix this, and it had stalled at ~38–42% of seller-fulfilled GMV (in the model). The refusal logic was rational: adoption asked sellers to give up control (their carrier rates, their handling declarations) for a benefit — accountability transfer — that was real but weakly priced and weakly communicated.

T — Lead the adoption-program design: diagnose the stall, rebuild the offer so adoption becomes the seller's rational choice, design the wave rollout with gates that protect both customer and seller, and define the measurement that keeps the program honest after handoff.

Why it mattered: with ~60% of GMV on manual configuration, the single largest driver of broken promises was seller-declared handling — sellers declared one day and hit it ~85% of the time (in the model), and the 15% became the marketplace's broken promise at the marketplace's brand cost. Left unfixed: the promise team keeps buffering around seller optimism (taxing every customer on the lane to absorb one seller's miss), the scorecard keeps punishing sellers for carrier variance they don't control (eroding the program's legitimacy), and adoption stays stalled because the offer prices neither the benefit nor the trade.

The metrics on the table, with their baselines: managed-settings share of seller-fulfilled GMV — ~38–42%, stalled (in the model); declared-handling adherence — ~85% on 1-day declarations (in the model); the offer's value

statement — unpriced (no seller could see what enrollment was worth in their own dollars); rollout mechanics — none designed; the measurement — enrollments counted, retention not.

ACTION — WHAT I PERSONALLY OWNED, HOW I DID IT, WHO ELSE WAS INVOLVED

A — Five gated phases (the baselines, the contract structure and the gate design are the design case's materials (nothing delivered); wave one is designed as the pilot; the adoption curve beyond it is the marketplace's, never claimed):

- **Discovery** — the refusal diagnosis: enrollment-funnel walk plus structured interviews with enrolled, refused and churned sellers (the refusals teach the most); the finding — fear of cost, loss of carrier control, distrust of the scorecard — an incentive-design problem, not a feature-marketing problem; the handling-adherence baseline written: declared 1-day, hit ~85%. *Exit bar:* the stall explained in the sellers' own words with the funnel's biggest drop-off named; the marketplace's product owner co-signed the diagnosis.
- **Plan & Design** — the offer rebuilt as a priced insurance contract: (a) transit automation (the marketplace picks the service), (b) observed handling time (the marketplace computes the seller's real handling speed from scan history — the seller stops declaring, killing self-reported optimism at the source), (c) a participating label purchase — full bundle earns carrier-delay excusal from the seller's scorecard and the fast badge where the math clears; partial adoption earns nothing, so the hedge is all-or-nothing and self-selecting. Plus the pricing surface: a personalized line in Seller Center — "enrollment would raise your projected GMV by $X/month," computed by the marketplace's team from the fast badge's measured conversion lift on that seller's assortment. *Exit bar:* the contract and its protection rules signed by product, seller ops and the scorecard owner; the design reference set (the dominant marketplace's equivalent bundle) documented, with the explicit decision *not* to copy its enforcement aggression while the marketplace's own fulfillment alternative was subscale.
- **Build & Test** — the marketplace's engineering built the enrollment flow, the observed-handling computation and the Seller Center line; I owned the verification design: shadow-run each enrolling seller's recent orders under managed settings before flipping — projected promise accuracy and badge eligibility computed on their own history, so day one is verified, not hoped. *Exit bar:* shadow results within tolerance of projection on the pilot cohort; the GMV-delta line reproducible by the marketplace's analytics from logged lift data.
- **Cutover / Go-Live (wave one)** — wave mechanics: cohorts boarded behind published graduation criteria (shadow-verified settings, observed-handling coverage, inventory-feed accuracy at the seller's nodes, scorecard-protection rules armed); a wave that fails a criterion does not board the next cohort — publicly. *Exit bar:* wave one boarded and stable; no enrolled seller's scorecard damaged by a carrier miss the contract had excused; the refusal-reason codes flowing back into the offer design.
- **Hypercare / Close** — the measurement handoff: the honest pair on the program board — activations per week *and* 30-day retention — plus share of enrolled GMV under full-bundle protection; the kill condition written (a protection promise the scorecard fails to honor stops enrollment until fixed). *Exit bar:* the marketplace's adoption PM owning the funnel, the pair and the gates; the design case ends on the contract and the mechanics, with the curve explicitly left to the marketplace's record.

The marketplace's product team owned Seller Center and the enrollment surfaces; engineering built the observed-handling computation and the protection rules in the scorecard pipeline; seller ops ran the cohorts; their analytics computed each seller's GMV-delta line. Mine: the refusal diagnosis, the insurance-contract structure and its all-or-nothing logic, the pricing surface concept, the shadow-verification gate, the wave mechanics and graduation criteria, the measurement pair, and the recommendation on enforcement posture — carrots over sticks until the marketplace's own fulfillment network was a credible alternative at scale.

The obstacle was the program's instinct to market the feature harder — more banners, more emails — when the stall was structural: an unpriced trade. The reframe that won the room: a seller who trusts their own ops should rationally keep control; a seller who doesn't should rationally convert — the offer's job is to make that self-selection visible in dollars, not to persuade everyone. The decision I challenged: requiring the label purchase as a hard cliff — sellers with negotiated carrier rates would read it as a tax. The recommendation: tier the protection with bundle depth rather than cliff it, and revisit when the fulfillment alternative scales. The trade went into the contract document as a priced row, not a hallway compromise.

RESULTS — HOW SUCCESS WAS MEASURED: $ · # · % · TIME · CUSTOMER · QUALITY

R — Primary deliverable: the signed insurance-contract design, the shadow-verification gate, the wave-one mechanics and the measurement pair — with the modeled economics labeled: ≈$3.7M/yr per +10 points of enrolled GMV from handling-miss reduction alone. The adoption curve after wave one is the marketplace's record, not mine.

- **$** — ≈$3.7M/yr per +10 pts of seller-fulfilled GMV enrolled, modeled: 100K orders/wk × (15% − 3%) handling-miss reduction × 50% breach-through × $12 × 52 (full chain in Table 4; the 3% and 50% are illustrative, the $12 is the model's stated assumption). No adoption "after" dollar — designed, not banked.
- **#** — One contract (three components, all-or-nothing), one pricing line per seller, one wave boarded; refusal interviews across enrolled, refused and churned cohorts; graduation criteria published before wave one (design-case record (not delivered)).
- **%** — Baseline ~38–42% of seller-fulfilled GMV enrolled, stalled (in the model); declared 1-day handling hit ~85% (in the model); the designed measurement: % of enrolled GMV under full-bundle protection, alongside the pair.
- **Time** — Shadow verification before any seller's flip (day one verified, not hoped); wave cadence gated on criteria, not calendar; 30-day retention as the clock that keeps enrollment honest.
- **Customer** — The customer's promise stops depending on a seller's optimistic declaration: observed handling replaces declared at the source; the fast badge appears only where the math clears — the promise shown is the promise kept.
- **Quality** — The protection promise armed and audited (no enrolled seller's scorecard damaged by an excused carrier miss in wave one — the wave's exit bar); refusal reason codes flowing back into the offer; the kill condition written before launch.

Against the goal stated above: the stall diagnosed as incentive design, the offer rebuilt so the trade is explicit and priced in the seller's own dollars, wave one boarded behind published gates, and the program handed over measuring the pair that can't be gamed. The trade behind the design was itself priced: enforcement tuned down from the reference mechanism's aggression — a churned seller is a strategic loss to a marketplace still in assortment-growth mode — carrots first, the stick deferred until the fulfillment alternative is credible.

L6 LEVEL EVIDENCE — what the interviewer pattern-matches against the Amazon L6 functional rubric

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	Why adoption stalled was unknown; I framed it as an incentive-design problem and tested it with funnel and refusal interviews.
Scope & influence	Client product and engineering, seller programs and sellers — none reporting to me; the contract needed all of them.
Execution	Offer redesign, shadow gate, wave criteria and the measurement pair; wave one boarded.
Impact	≈$3.7M/yr per ten points of enrolled GMV, modeled; no claim on the adoption curve.
Process improvement	Graduation gates and an honest measurement pair (activations and 30-day retention) with a kill condition.
Complexity	Adverse selection, all-or-nothing bundling, shadow replay against declared settings.
Root cause	Declared handling is a bid for placement; the stall was incentives, not awareness.

THE FIVE FACETS NEW — data analysis · solution design · math & data logic · implementation · probe questions; each labeled so the interviewer can see all five are present

1 · Data analysis	Data: enrollment funnel, refusal interviews, declared vs observed handling (85% hit rate), the GMV share on managed settings (~38–42%). Revealed: optimistic declaration; an unpriced benefit.
2 · Solution design	Options: more marketing · a priced all-or-nothing contract · mandatory enrollment. Chosen: insurance contract with shadow gate and published graduation criteria.
3 · Math & data logic	Math: 1M × 60% × 15% × 50% × $12 = $540,000/wk on the manual book; +10 pts → 100K × 12% × 50% × $12 × 52 = $3,744,000/yr; flip rule c = 11 misses in 200 shadow orders.

4 · Implementation	Implementation: diagnose → contract → shadow gate → waves behind criteria → activations × 30-day retention.
5 · Probe questions	Probe questions: interval on 85% · sensitivity of $3.7M · false-pass of the shadow gate · churn vs growth — see Trap Drills.

PROBING — CHALLENGE Q&A (MASTER RECORD) PLUS THE STATISTICAL QUESTIONS

***Challenge* — Why did you choose this story to illustrate Think Big?**

Because the move is structural, not incremental: the program stopped marketing a settings toggle and started selling an insurance contract — accountability transfer, priced per seller, self-selecting at marketplace scale. Thinking big here meant redesigning the incentive so thousands of independent sellers each make the right call on their own.

***Probing* — Why did you choose to focus on these results? What other results were important?**

The contract design leads because it is the thing I can honestly claim — the diagnosis, the structure, the gates, the measurement. Also important: the enforcement-posture recommendation (carrots until the alternative scales) and the kill condition — a protection promise the scorecard fails to honor stops enrollment, because one broken protection kills the program's legitimacy faster than slow adoption does.

***Probing* — You mentioned dollars — what percentage change is that year over year?**

None claimed — the ≈$3.7M/yr is per ten points of enrolled GMV, modeled from the handling baseline, and the curve itself is the marketplace's record. I give the unit economics so the investment argument is quantitative; I don't book the outcome.

***Probing* — I'm concerned you're taking credit for a program you didn't run to completion — tell me more.**

That's exactly why the claim is scoped: mine is the diagnosis, the contract, the gates, wave one and the measurement pair; the marketplace's is the curve. I'd rather under-claim a design than over-claim an outcome — the same discipline as S17, where I refuse the award dollar on the carrier bid.

***Challenge* — What were the lessons learned? What would you have done differently?**

Lesson: adoption stalls are usually incentive-design problems wearing feature-marketing costumes — price the trade and the funnel moves. Differently: start the refusal interviews before touching the funnel data; the sellers' own words located the drop-off faster than the analytics did, and I ran them second.

***Challenge* — How would you implement this at Amazon?**

Amazon runs the reference version of this contract — observed handling, settings automation, protected labels, all-or-nothing accountability transfer. What I'd bring is the posture judgment: knowing when the contract's teeth fit the business (a mature fulfillment alternative, churn tolerance) and when they don't — and the measurement pair, because enrollments without retention is churn wearing a growth costume at any company.

***Challenge* — How did these results compare to your actual goals?**

The case's stated goals were a diagnosed stall, a rebuilt offer, a gated wave one and an honest measurement handoff — all four specified in the design. The goal was never "move the share N points under my name"; that outcome belongs to the owners who run the waves.

PHASE DEEP-PROBE BANK — Q&A (12). *Answer the phase asked, then stop.*

Discovery — How did you know discovery was done?

When the stall had one explanation that survived the sellers' own words, the funnel data and the product team's review: a real benefit, unpriced and weakly communicated, traded against a visible loss of control. The exit memo named the funnel's biggest drop-off and the three refusal reasons in rank order.

Why interview churned sellers, not just refusers?

Because churn is the expensive refusal — someone who tried the program and left knows exactly which promise broke. Wave-one's protection-audit exit bar came directly from a churned seller's story about a scorecard ding the program should have excused.

Plan & Design — Why all-or-nothing instead of à la carte?

Because partial adoption keeps the adverse selection: a seller who keeps declared handling keeps the optimism that breaks promises. Cede all three controls and the marketplace can underwrite you; keep any one and you keep the risk. The bundle is what makes the contract insurable — and self-selecting.

Why does observed handling matter so much?

It kills self-reported optimism at the source. Declared handling is a bid for placement (declare one day, hit it 85%); observed handling is a measurement. Moving the promise onto what sellers actually do — rather than what they say — is the single largest accuracy lever in the seller-execution family.

What was the reference mechanism and what did you refuse to copy?

The dominant marketplace's equivalent: the same three-part bundle with full accountability transfer, enforced aggressively. We copied the contract structure and the grain. We did not copy the enforcement aggression or the churn tolerance — this client was still in assortment-growth mode, its fulfillment alternative subscale, so a churned seller was a strategic loss. Tiered protection instead of a cliff, revisited when the alternative scales.

Build & Test — What exactly did the shadow run verify?

Each enrolling seller's recent orders replayed under managed settings: projected promise accuracy, badge eligibility, and the scorecard-protection rules firing where they should. Day one verified on the seller's own history, not hoped — the same calibration-before-onboarding toll as my Flexport waves (S11).

How was the GMV-delta line computed and policed?

The marketplace's analytics computed it per seller from the fast badge's measured conversion lift applied to that seller's assortment — their model, reproducible from logged lift data. My rule on it: the line is a projection and labeled as one in Seller Center; an unlabeled promise there would be the program lying to its own sellers.

Cutover — What were the wave-one graduation criteria?

Shadow results within tolerance of projection; observed-handling coverage on the cohort; inventory-feed accuracy at the seller's ship-from nodes (a stale feed causes cancellations — the worse defect); and the protection rules armed and audited. A wave that failed a criterion did not board the next cohort — publicly.

What was the kill condition?

A protection promise the scorecard fails to honor — an enrolled seller dinged for an excused carrier miss — stops enrollment until fixed. The contract's credibility is the product; one broken protection spends it faster than any growth banks it.

Hypercare — Why activations *and* 30-day retention?

Because enrollments without retention is churn wearing a growth costume. The pair is the honest read: throughput says the funnel works; retention says the contract kept its promise. A program graded on activations alone will board sellers it should have fixed first.

What flowed back into the offer after wave one?

Refusal and churn reason codes, as data: which component sellers feared (the label requirement led), which protection they doubted, where the GMV-delta line read as marketing instead of math. Overrides with reasons are data; silent refusals are a funnel you can't fix.

Cross-phase — What did you refuse?

An adoption target under my name (the curve is the marketplace's), a hard label-purchase cliff (a tax on sellers with negotiated rates — tiered instead), enrollment pushes ahead of the shadow gate (day one must be verified), and counting activations without retention. Every refusal is in the contract document as a priced row.

Analytics — How sure are you that handling adherence is 85%?

The 85% is a in the model baseline. As statistics: a seller with 100 shipments at 85% on time has a 95% Wilson interval of 76.7% to 90.7%; with 400 shipments, 81.2% to 88.2%. That is why “observed handling” needs enough scan history per seller before it replaces a declaration.

Analytics — What does the shadow gate actually test?

Replay a seller’s recent orders under managed settings and flip only within tolerance of the projection. At a projected 3% miss rate on 200 orders, flipping when misses ≤ 10 has a 4.0% false-reject rate on a seller who truly is at 3%, and detects a seller truly at 6% with 66% probability. Illustrative gate; the record is shadow-run-before-flip.

STATISTICAL SPINE — INTERVALS, SENSITIVITY, SHADOW GATE, RETENTION (EXTRA TABLES)

The record is the design case and the modeled economics; the tables below add interval and sensitivity arithmetic. The adoption curve after wave one is the marketplace’s and is not claimed.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Orders on manual configuration	`1,000,000 × (1 − 40%) = 600,000/wk`	enrolled ≈ 38–42%, 40% midpoint (in the model)	600,000/wk
2	Seller-made handling misses	`600,000 × 15% = 90,000/wk`	85% hit rate (in the model)	90,000/wk
3	Breach-through	`90,000 × 50% = 45,000/wk`	50% illustrative	45,000/wk
4	Cost of the manual book	`45,000 × $12 = $540,000/wk`	$12 breach bundle (model assumption)	≈$540,000/wk

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	+10 points of enrolled GMV	`1,000,000 × 10% = 100,000 orders/wk`	illustrative book	100,000/wk
2	Handling misses avoided	`100,000 × (15% − 3%) = 12,000/wk`	3% post-fix illustrative	12,000/wk
3	Breaches avoided	`12,000 × 50% = 6,000/wk`	50% illustrative	6,000/wk
4	Per week / per year	`6,000 × $12 = $72,000/wk; × 52 = $3,744,000`	modeled	≈$3.7M/yr per 10 pts
5	Sensitivity — miss reduction 6 / 12 / 15 pts	`$1.87M / $3.74M / $4.68M`	one-at-a-time	$1.87M–$4.68M
6	Sensitivity — breach-through 25% / 50% / 75%	`$1.87M / $3.74M / $5.62M`	one-at-a-time	$1.87M–$5.62M
7	Sensitivity — breach cost $6 / $12 / $18	`$1.87M / $3.74M / $5.62M`	one-at-a-time	$1.87M–$5.62M
8	Shadow gate	`n = 200, p₀ = 3%: reject if misses ≥ 11; false-reject 4.0%; power at 6% = 66%`	binomial, illustrative	c = 11
9	Churn in a growth costume	`200 enrollments × 50% retained = 100; 100 × 90% = 90`	illustrative weekly cohorts	raw enrollments say 2×; retained say 1.1×

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
10	Retention estimate, one wave	`40 of 50 retained = 80%; Wilson [67%, 89%]`	illustrative wave size	80% ± ≈12 pts

BUSINESS IMPACT MODEL — KPI TREE, NUMBERS, THE MATH

```
Promise kept at the source + adoption that sticks (primary outcome)
+- Handling-miss rate on manual-config GMV (flow) -> declared ~85% kept
|    miss -> breach-through -> broken promise -> WISMO + trust decay
+- Enrolled GMV share (stock) -> ~38-42% stalled -> waves behind gates
|    (loop) priced offer -> rational enrollment -> observed handling
|           -> fewer misses -> badge earned -> conversion lift -> more GMV
+- Protection credibility (stock) -> kill condition; audit per wave
+- Measurement honesty -> activations/wk x 30-day retention (the pair)
+- Unit economics -> ~$3.7M/yr per +10 pts enrolled GMV (modeled)
```

DRIVER	BASELINE	AFTER (DESIGNED)	$/YR	BASIS
Enrolled share of seller-fulfilled GMV	~38–42%, stalled	waves behind gates; curve unclaimed	—	in the model baseline
Handling adherence on declared 1-day	~85%	observed handling replaces declared; ~97% modeled	inside the unit economics	85%: in the model; 97%: illustrative
Unit economics per +10 pts enrolled GMV	—	≈6,000 breaches/wk avoided	≈$3.7M	modeled (Table 4; $12 assumption)
Offer pricing surface	benefit abstract	personalized GMV-delta line per seller	—	design-case record (not delivered) (computed in the model)
Program honesty	enrollments counted	activations/wk × 30-day retention + full-bundle share	—	design-case record (not delivered)

If challenged. *"Your result is a design, not an outcome."* — "Yes — and I say exactly that. Mine is the diagnosis, the contract, the gates, wave one and the measurement pair; the adoption curve is the marketplace's record. The production-record version of me running an adoption machine end-to-end is S11: 7 to 68 behind published gates." *"The $3.7M rests on two illustrative rates."* — "It does — the 3% post-fix miss rate and the 50% breach-through are labeled illustrative; the 85% baseline and the $12 are the case materials' own figures. Halve both assumptions and the unit is still about a million a year per ten points — the argument survives." *"Why not just mandate enrollment?"* — "Because a mandate spends seller trust the marketplace hasn't earned yet — and a churned seller is a strategic loss in assortment-growth mode. The contract makes enrollment the rational hedge; mandates are for after the fulfillment alternative is credible."

THE MATH — STEP-BY-STEP DERIVATION

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	GMV on manual configuration	`1 − enrolled share = 1 − 40% = 60%`	enrolled ~38–42% (in the model); 40% midpoint used	≈60% of seller-fulfilled GMV on declared settings
2	Orders on manual config	`1,000,000 × 60% = 600,000 / wk`	~1M orders/wk illustrative book	≈600K orders/wk
3	Handling misses	`600,000 × (1 − 85%) = 600,000 × 15% = 90,000 / wk`	declared 1-day handling hit ~85% (in the model)	≈90K seller-made misses/wk

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
4	Breach-through	`90,000 × 50% = 45,000 / wk`	a handling miss of a day typically exhausts the buffer; 50% breach-through (illustrative)	≈45K broken promises/wk from handling alone
5	Cost of the manual book	`45,000 × $12 = $540,000 / wk`	$12 breach bundle (the model's stated assumption)	≈$540K/wk of handling-driven breach cost
6	Why it persists	`declared handling = a bid for placement; adoption = control traded for an unpriced benefit`	adverse selection + unpriced trade (in the model diagnosis)	a stall no banner fixes

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	The contract	`protection ⇔ (transit automation) AND (observed handling) AND (participating label)`	all-or-nothing bundle (design case)	full bundle → carrier-delay excusal + badge where the math clears
2	Observed handling effect	`miss rate 15% → ~3% on enrolled orders`	handling set from scan history, not declaration; 3% illustrative	−12 points of handling misses on enrolled GMV
3	Pricing the benefit	`seller line = conversion lift × seller's eligible assortment GMV = "$X/month"`	computed in the model from measured badge lift (design)	the trade visible in the seller's own dollars
4	Self-selection logic	`trusts own ops ⇒ keeps control and risk; doesn't ⇒ converts`	incentive design, not persuasion	adoption as the rational hedge
5	Shadow gate	`replay seller's recent orders under managed settings; flip only within tolerance of projection`	verification design	day one verified, not hoped
6	Wave mechanics	`cohort boards ⇔ all published criteria pass; fail one ⇒ hold, publicly`	graduation gates (design; the S11 motion)	adoption earns its expansion
7	The honest pair	`program health = activations/wk AND 30-day retention AND full-bundle share`	measurement design	growth that can't be faked by churn

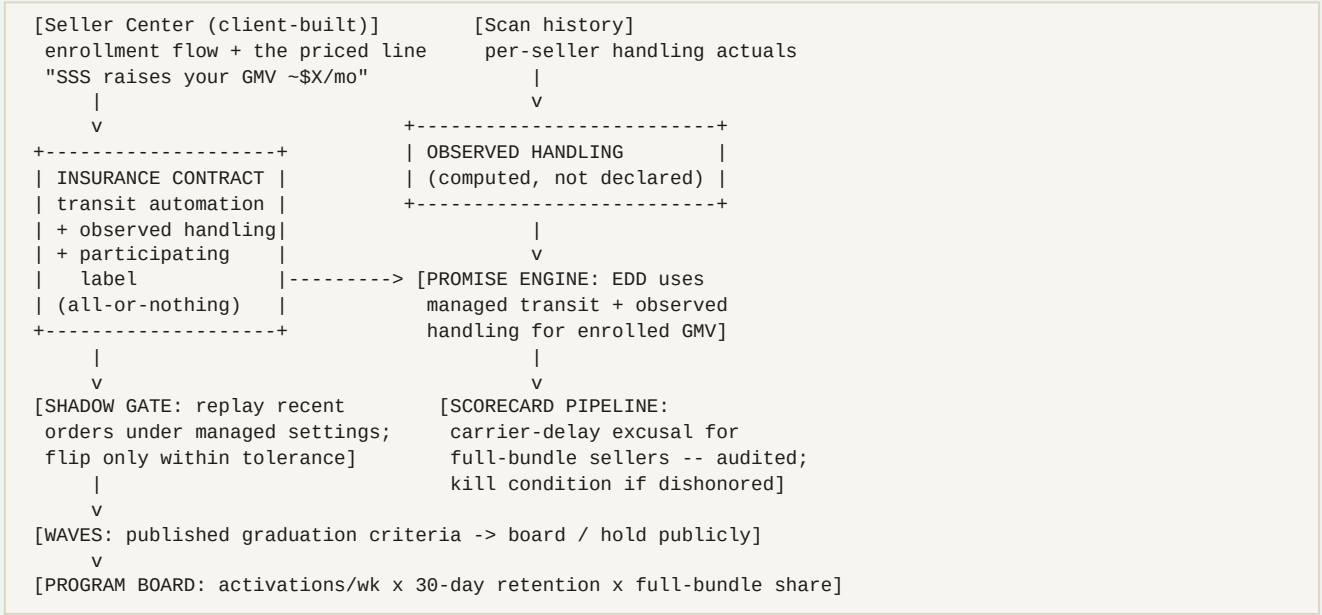

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	The offer	settings toggle, benefit abstract	priced insurance contract, benefit in seller dollars	design-case record (not delivered)
2	Handling input on enrolled GMV	declared (15% miss)	observed (~3% miss, modeled)	15%: in the model; 3%: illustrative
3	Rollout mechanics	none (push marketing)	shadow gate + waves behind published criteria; wave one boarded	design-case record (not delivered)
4	Program measurement	enrollments	activations/wk × 30-day retention × full-bundle share; kill condition armed	design-case record (not delivered)
5	Enrolled GMV share	~38–42% stalled	curve unclaimed — the marketplace's record	in the model baseline; honesty rule

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Orders in +10 pts of enrolled GMV	`1,000,000 × 10% = 100,000 / wk`	~1M orders/wk illustrative book	100K orders/wk move onto the contract
2	Handling-miss reduction	`15% − 3% = 12 points`	15% in the model; 3% illustrative post-fix rate	12 pts fewer misses
3	Misses avoided	`100,000 × 12% = 12,000 / wk`	rows 1 × 2	≈12K misses/wk avoided
4	Breaches avoided	`12,000 × 50% = 6,000 / wk`	50% breach-through (illustrative)	≈6K broken promises/wk avoided
5	Weekly value	`6,000 × $12 = $72,000 / wk`	$12 breach bundle (the model's stated assumption)	≈$72K/wk
6	Annualized	`$72,000 × 52 = $3,744,000`	row 5 × 52 (modeled)	≈$3.7M/yr per +10 pts enrolled
7	Not claimed	`adoption curve × unit economics = the marketplace's outcome`	honesty rule	unit economics only; conversion-lift upside also excluded

SOLUTION FLOW — THE SYSTEM & DATA MAP

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Post-fix handling-miss rate (illustrative)	6%	3%	2%
Breach-through on a handling miss (illustrative)	30%	50%	70%
Breach cost (model assumption)	$6	$12	$18
Breaches avoided per +10 pts (/wk)	≈2,700	≈6,000	≈9,100
Modeled $/yr per +10 pts enrolled	≈$0.8M	≈$3.7M	≈$8.5M

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

"The honest version first: what I designed is the contract, not the curve. The program was stalled around forty percent of seller-fulfilled GMV because it asked sellers to trade control for an unpriced benefit — so we rebuilt it as insurance: give up transit settings, declared handling and the label, and the marketplace absorbs carrier-delay accountability and shows you what the fast badge is worth on your own assortment, in dollars. The unit economics are modeled and I label them: on the case materials' own baseline — sellers declaring one-day handling and hitting it eighty-five percent of the time — every ten points of GMV that enrolls is worth about three point seven million dollars a year in avoided broken promises at the model's twelve-dollar breach cost. Wave one boarded behind published gates; the adoption curve after that belongs to the marketplace's owners, and I say so."

BEHAVIORAL PACK NEW — FOUR QUESTIONS THIS STORY ANSWERS, FOUR SEPARATE 90-SECOND ANSWERS (EACH FROM A DIFFERENT MOMENT OF THE STORY)

Q1 Tell me about a time you found the real reason a program stalled. DIVE DEEP

Open (first two sentences): Adoption was stuck near forty percent and everyone wanted a better banner. The data said sellers were making a rational trade.

STAR (≈90 s): Situation: a managed-shipping program stalled at ~38–42% of seller-fulfilled GMV. Task: diagnose why. Action: enrollment-funnel and refusal interviews; the pattern was control traded for an unpriced, weakly communicated benefit, and declared one-day handling that sellers hit about 85% of the time — adverse selection. Result: the diagnosis moved the work from marketing to incentive design; the contract followed.

Land this number: 85% handling adherence; ~38–42% enrolled. · **Pivot to NACF:** NACF vendor ASN accuracy has the same incentive: declared dates are bids. · **Do NOT say:** Do not claim the adoption curve after wave one.

Q2 Tell me about a time you redesigned an offer instead of pushing the existing one. INVENT AND SIMPLIFY

Open (first two sentences): I made it one contract: give up transit settings, declared handling and take the label — and the marketplace absorbs carrier delays.

STAR (≈90 s): Situation: sellers refused a toggle. Task: a design they would choose. Action: an all-or-nothing insurance bundle — transit automation + observed handling + participating label — with a personalized GMV-delta line in Seller Center showing the benefit in the seller’s own dollars. Result: signed contract design and wave-one mechanics; modeled ≈$3.7M a year per ten points of enrolled GMV.

Land this number: ≈$3.7M/yr per 10 pts (modeled). · **Pivot to NACF:** A priced, bundled commitment beats a toggle at NACF too. · **Do NOT say:** Do not call $3.7M a result.

Q3 Tell me about a time you were precise about what was yours. EARN TRUST

Open (first two sentences): I claim the contract design and the wave-one mechanics. The adoption curve after that belongs to the marketplace, and I say so.

STAR (≈90 s): Situation: a program whose headline number — enrolled GMV — was moved by many hands. Task: keep my claim to what I did. Action: the honesty pair — activations per week and 30-day retention — so growth cannot be faked by churn; and in every retelling, “modeled” is in the same breath as the dollar. Result: a claim that survives a reference check.

Land this number: Wave one boarded; $3.7M modeled. · **Pivot to NACF:** In an Amazon interview, the line between “I designed” and “we shipped” is the line. · **Do NOT say:** Do not annualize or extrapolate the curve.

Q4 **Tell me about a time you held a high bar on rollout quality.** INSIST ON THE HIGHEST STANDARDS

Open (first two sentences): Day one is verified, not hoped: we replayed a seller's orders under managed settings before flipping.

STAR (≈90 s): Situation: flipping a seller wrongly breaks a promise. Task: a gate. Action: shadow-run before flip within tolerance of the projection; waves behind published graduation criteria — fail one, hold, publicly. As a design check: at n = 200 orders and a 3% projection the gate rejects a good seller 4.0% of the time and catches a 6% seller 66% of the time. Result: wave one boarded behind the criteria.

Land this number: c = 11 misses in 200 orders (illustrative). · **Pivot to NACF:** A NACF vendor-lane activation gate on valid-ASN rate, as in S9. · **Do NOT say:** Do not quote gate numbers as the record.

SAME STORY, THREE ANGLES NEW — THREE DIFFERENT OPENERS, HEADLINE METRICS AND LPS FROM THE SAME FACTS

(I) DATA / ANALYTICAL

LP: Dive Deep

Open: "Declared handling was a bid for placement."

Headline metric: 85% hit rate; manual book ≈$540K/wk breach cost (model)

- 1M × 60% × 15% × 50% × $12.
- 85% interval at n = 100: [76.7%, 90.7%].
- Contract: observed handling replaces declaration.
- Sensitivity $1.9M–$5.6M on miss reduction.

(II) CONFLICT / INFLUENCE / BACKBONE

LP: Have Backbone; Earn Trust

Open: "I would not put the adoption curve on my résumé."

Headline metric: claim = contract + wave-one mechanics

- The curve is the marketplace's.
- "Modeled" in the same breath.
- Kill condition armed on the measurement pair.
- Honest pair: activations × retention.

(III) FAILURE — LEARNING — WHAT I WOULD DO DIFFERENTLY

LP: Learn and Be Curious

Open: "The incentive diagnosis was not my first hypothesis."

Headline metric: refusal interviews changed the frame from marketing to incentives

- The funnel alone suggested awareness.
- Interviews showed an unpriced trade.
- I would instrument seller-level retention earlier.
- VERIFY-WITH-RAJESH that this was the order of discovery.

TRAP DRILLS NEW — THE THREE NASTIEST FOLLOW-UPS A STATISTICALLY RIGOROUS INTERVIEWER THROWS

T1 **"Your $3.7M — which assumption dominates?"**

The numbers: +10 pts: 100,000 × 12% × 50% × $12 × 52 = $3,744,000; miss reduction 6/15 pts → $1.87M/$4.68M; breach-through 25/75% → $1.87M/$5.62M; breach cost $6/$18 → $1.87M/$5.62M.

Say exactly: "It is a product of four inputs, so a halving or doubling of any one moves it proportionally — from about $1.9 million to $5.6 million on breach-through, $1.9 to $5.6 on the breach cost — and I call it modeled in the same breath; the marketplace's own data replaces each input."

T2 **"Eighty-five percent — what is the interval, and is 15% → 3% plausible?"**

The numbers: n = 100: [76.7%, 90.7%]; n = 400: [81.2%, 88.2%]; 3% is illustrative.

Say exactly: "On a hundred shipments eighty-five percent is anywhere from about 77 to 91; the fifteen-to-three-point effect is an illustrative target — observed handling is the mechanism, and I would not quote three as measured."

T3 **"Enrollments are up — is the program working?"**

The numbers: 200 enrollments × 50% retained = 100; 100 × 90% = 90; Wilson at 40/50 retained: [67%, 89%].

Say exactly: "Not necessarily — two hundred enrollments at fifty percent retention retain a hundred and a hundred enrollments at ninety retain ninety; raw enrollments say twice as good, retained activations say about the same, so the pair is activations per week and thirty-day retention, with a kill condition."

E7 — Elementum design engagement (new-market broadband build) — equipment forecast-to-buy: a newsvendor first buy, risk-pooled central stock and a ±20% two-week re-forecast trigger, with the statistics behind each (design, not run) NEW

LPs this story serves here: Learn and Be Curious (primary — the toolkit applied, labeled) · Think Big (a repeatable launch template) · Are Right, A Lot (a decision under maximum uncertainty) · Customer Obsession (install delays caused by stockouts → 0)
Process family: Plan / Source seam — forecast-to-buy for a market launch (master E7; Google Fiber-style field-install build; finished-kit grain, no component explosion)

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH NEW

- **Learn and Be Curious** — I applied the newsvendor critical ratio and risk pooling from the MIT MicroMasters toolkit to a cold-start launch — labeled as the toolkit, not as a program I ran.
- **Think Big** — The design is a template for market N+1: build plan → adoption curve → requirement → measured lead times → first buy held central → forward-deploy as sell-through proves the curve.
- **Are Right, A Lot** — Under maximum uncertainty I priced the decision — Cu ≈ $300 vs Co ≈ $3/month → CR 0.99 — and wrote the trigger that proves the curve wrong in two weeks, not two quarters.
- **Customer Obsession** — The metric is install delays caused by stockouts → 0 in the first 90 days — a missed install is a customer waiting, priced at ≈$300 in the model.

Honesty label. Design engagement, not a run record. I have not owned a market-launch forecast end to end; the forecast number belongs to Planning — I own the equation, the measurement and the triggers (master E7). The newsvendor and pooling formulas are the MIT MicroMasters toolkit, labeled. All volumes, CVs and correlations here are illustrative. The master's E-series does not name the client; the brief ties them to Google Fiber. VERIFY-WITH-RAJESH that you are comfortable saying "Google Fiber" aloud — otherwise say "a broadband build-out client." Finished-kit grain only — no component explosion.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. A broadband client launches a new market: build sites ramp by month, demand follows an adoption curve with no local history, and long-lead equipment takes weeks to months to arrive. A missed install means a re-roll and deferred revenue; extra stock means holding cost and stranding risk. Task. Design the forecast-to-buy chain so installs are never delayed by stockouts and stranded stock stays inside a band. Action. Four decisions, each with its arithmetic. First buy: a newsvendor — a missed install costs about $300, a unit held a month about $3, so the critical ratio is 0.990 and I order the 99th percentile of the first quarter's demand for the core unit; accessories with a lower miss cost sit at the 70th. Held central: one pool covers several markets' variance, √k instead of k — if the markets are uncorrelated, which I would measure. Trigger: actual take-rate versus the curve beyond ±20% for two consecutive weeks forces a new forecast version. Demand enters planning once, through the engine — no spreadsheets beside it. Result. Primary metric: install delays caused by stockouts → 0 in the first 90 days of a launch. Illustrative dollar: 2,000 installs a month × 3% reschedules × $300 ≈ $18K a month, about $216K a year per market, plus about $100K of stranding avoided — design arithmetic, not a program result.

20-SECOND VERSION NEW

For a new-market build I would buy the core unit at the 99th percentile of first-quarter demand because a missed install costs 100× a unit-month of holding, hold it central so uncertainty pools, and re-forecast when the take-rate leaves ±20% of the curve two weeks running.

NACF BRIDGE — ONE SENTENCE

NACF placement for a new FC or a new product launch has the same shape: a critical-ratio first buy, central-first, and a variance trigger — INV-C's placement model plus INV-B's service-level logic.

SITUATION / TASK — THE PROBLEM SPACE

S — Market N launches: build sites ramp by month from the project system's build plan; demand follows an adoption curve with no local history; kits and long-lead equipment have vendor lead times of weeks to months. The books: the project system for the build plan, Planning for the adoption curve, SAP MRP for supply.

T — Design the forecast-to-buy chain so installs are never delayed by stockouts and stranded stock stays inside a band — the equation, the measurement and the triggers; Planning owns the forecast number.

Baselines on the table (illustrative): 2,000 installs a month per market · 3% of installs rescheduled for stockouts · missed install ≈ $300 · holding ≈ $3/month · first buy ≈ $500K.

ACTION — FIVE GATED PHASES (DESIGN)

- **Discovery** — restated the problem as a stock-and-flow map — build plan → sites passed → adoption curve × marketing → install demand → requirement by SKU × week → MRP on measured lead times → POs → central pool → market transfers. Exit bar: the three books of record named; the primary metric agreed.
- **Plan & Design** — newsvendor first buy; central-first with risk pooling; re-forecast trigger ±20% for two weeks; invariants: demand enters planning once, lead times are measured distributions (the S8 rule), floors with hold-until dates so one market cannot steal another's launch. Exit bar: each rule has its arithmetic on one page.
- **Build & Test** — the arithmetic below — newsvendor cost curve, pooling under correlation, trigger false-alarm and detection — run on illustrative inputs; failure modes listed (a borrowed adoption curve, a brochure lead time, manual loads). Exit bar: every rule survives its own sensitivity.
- **Cutover & Go-Live (design)** — launch plan: first buy held central; forward-deploy via transfers as sell-through proves the curve; bias sign published weekly from month two. Exit bar: install delays caused by stockouts = 0 in the first 90 days.
- **Hypercare / Close (design)** — MAPE and bias per SKU × market × week; days-of-cover inside the band; the template re-run for market N+1. Exit bar: a floor breach is a governed screen with a reason code, not an email.

Influence and ownership. This is a design I owned the equation of; Planning owns the forecast, Finance the unit costs, Marketing the adoption curve. The backbone content is the invariant: demand enters planning exactly once, through the engine — manually loaded requirements beside it are blocked — and need floors stop one market starving another.

RESULTS — DESIGN OUTCOMES, ALL ILLUSTRATIVE

- **Primary metric (design target)** — install delays caused by stockouts → 0 in the first 90 days of a launch.
- **$** — 2,000 installs/month × 3% × $300 = $18,000/month ≈ $216,000/yr per market; 20% × $500K = $100,000 of stranding avoided by holding central (master, illustrative) — never a program result.
- **Statistics** — critical ratio 0.990 → z = 2.33 → first-quarter buy 9,495 units on a 6,000-unit mean; pooling saves 50% of buffer at ρ = 0 and 31% at ρ = 0.3 (k = 4).
- **Quality** — MAPE and bias per SKU × market × week from month two; bias sign before magnitude.
- **Honest limit** — not run end to end; the forecast is Planning's.

L6 LEVEL EVIDENCE — what the interviewer pattern-matches against the Amazon L6 functional rubric

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	A launch with no history; I restated it as a stock-and-flow problem with a priced objective.
Scope & influence	Planning, Finance, Marketing, vendors and field operations; the design is the influence.
Execution	Newsvendor, pooling, trigger and invariants each with arithmetic and a failure-mode list.
Impact	Design arithmetic: ≈$216K/yr per market of avoided reschedules plus ≈$100K stranding avoided (illustrative).
Process improvement	A launch template for market N+1; demand enters once; floors with hold-until dates.
Complexity	Cold-start demand, correlated markets, long-lead supply, a borrowed adoption curve risk.
Root cause	Launch stockouts come from an unpriced first buy and an untested curve — not from vendor behavior.

THE FIVE FACETS NEW — data analysis · solution design · math & data logic · implementation · probe questions; each labeled so the interviewer can see all five are present

1 · Data analysis	Data (design): build plan by month, adoption curve by archetype market, install-reschedule reasons joined to the supply view, vendor lead-time distributions (S8). Revealed (illustrative): the 3% baseline reschedule rate corresponds to ordering near the 79th percentile.
2 · Solution design	Options: forecast mean · p79 · p99 first buy; forward-deploy vs central-first; trigger at ±10% / ±20% / ±30%. Chosen: p99 on the core unit, p70 accessories, central-first, ±20% two weeks.
3 · Math & data logic	Math: CR = 300 ÷ 303 = 0.9901; z = 2.330; Q = 6,000 + 2.330 × 1,500 = 9,495; expected short σ·L(z) = 5.0; pooling σ√(k + k(k−1)ρ); trigger DP on consecutive exceedances.
4 · Implementation	Implementation: stock-and-flow map → rules with arithmetic → invariants → launch plan → weekly MAPE/bias → template for N+1.
5 · Probe questions	Probe questions: why p99 · what if the CV is wrong · does pooling survive correlation · trigger false alarms — see Trap Drills.

PROBING — CHALLENGE Q&A TUNED TO A STATISTICIAN

Analytics — Show the newsvendor logic with numbers.

Critical ratio = Cu ÷ (Cu + Co) = 300 ÷ 303 = 0.9901, so order the 99.0th percentile of first-quarter demand: z = 2.330. With mean 6,000 and σ = 1,500 (CV 25%, illustrative) that is 9,495 units; expected shortfall σ·L(z) = 5.0 units, expected leftover 3,500; expected cost $12,009, versus $58,234 at the 79th percentile.

Analytics — Why does the master's 3% reschedule rate matter?

Because it pins the baseline: a 3% shortfall on a 25% CV is L(z) = 0.03 ÷ 0.25 = 0.12 → z ≈ 0.8, the 79th percentile — a first buy near the 79th percentile reproduces the 3% and the $18K a month. The design moves it to the 99th percentile: expected shortfall 0.08% of installs. Illustrative CV; the master's 3% is the anchor.

Analytics — Your CV is a guess. What if it is 35%?

Then a buy sized for 25% at the 99th percentile — 9,495 — sits at z = 1.66 on the true spread: a 4.8% chance of running short and an expected shortfall of 42 units, versus 5.0. The policy is robust in direction and fragile in tail: so the buy is re-sized as soon as the first weeks' CV is observed, and the trigger exists for the same reason.

Analytics — Why is the central pool better — and when does it stop being better?

Pooling k markets cuts the buffer from k·zσ to z·σ·√(k + k(k−1)ρ): at k = 4 and independence, 50%; at ρ = 0.3, 31.1%; at ρ = 0.6, 16.3%; at ρ = 1, nothing. New markets share a product, a campaign and an adoption archetype, so ρ is probably not zero — I would measure it on analog markets before promising the saving. VERIFY-WITH-RAJESH

Shadow / closing — What would you do differently?

Measure the cross-market correlation on analog markets before quoting a pooling saving, and archetype-review the adoption curve with Marketing first — a curve borrowed from a non-analog market is the failure mode that voids everything else.

BUSINESS IMPACT MODEL — WHAT THE FORECAST-TO-BUY DESIGN IS FOR

```
Install delays caused by stockouts -> 0 (first 90 days)
+- First buy at the critical ratio: p99 core unit, p70 accessories
+- Central pool: one buffer covers several markets (sqrt k, if uncorrelated)
+- Re-forecast trigger: take-rate vs curve beyond +/-20% for 2 weeks
+- Invariants: demand enters once; measured lead times; floors with hold-until
+- Dollars (illustrative): reschedules avoided + stranding avoided
```

DRIVER	BASELINE	AFTER	$	BASIS
Reschedules from stockouts	3% of 2,000 installs/month	→ ≈0	$18,000/month ≈ $216,000/yr per market	master illustrative
Stranding avoided	20% of a $500K first buy in-market	held central	≈$100,000	master illustrative
Expected first-quarter cost, core unit	p79: $58,234	p99: $12,009	$46,225 lower	newsvendor arithmetic (illustrative)

If challenged. *"Did you save $216K a year?"* — "No — it is design arithmetic on illustrative inputs; I did not run this launch."

THE MATH — STEP-BY-STEP DERIVATION

Table 1 — before: the baseline in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Baseline (master)	`2,000 × 3% × $300 = $18,000/month; × 12 = $216,000/yr`	master E7 illustrative	$216,000/yr per market
2	What the 3% implies	`shortfall fraction = CV × L(z) → 0.03 = 0.25 × L(z) → L(z) = 0.12 → z ≈ 0.8 (p79)`	standard normal loss function	baseline ≈ p79 first buy
3	The 3-month demand	`μ = 2,000 × 3 = 6,000; σ = 25% × 6,000 = 1,500`	CV 25% illustrative	σ = 1,500
4	Stranding at risk	`20% × $500,000 = $100,000`	master illustrative	$100,000

Table 2 — the fix: the newsvendor first buy, every row substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Critical ratio	`Cu ÷ (Cu + Co) = 300 ÷ 303 = 0.9901 → z = Φ⁻¹ = 2.330`	Cu ≈ $300; Co ≈ $3/month (master)	order the 99.0th percentile
2	Buy at p50	`z = 0.0000: Q = 6,000 + 0.0000 × 1,500 = 6,000; short σL = 598.413; left σ(z+L) = 598.413; cost = 598.413 × $300 + 598.413 × $3 = $181,319`	normal demand, one-month holding (illustrative)	$181,319
3	Buy at p79	`z = 0.8000: Q = 6,000 + 0.8000 × 1,500 = 7,200; short σL = 180.311; left σ(z+L) = 1,380.311; cost = 180.311 × $300 + 1,380.311 × $3 = $58,234`	normal demand, one-month holding (illustrative)	$58,234
4	Buy at p90	`z = 1.2816: Q = 6,000 + 1.2816 × 1,500 = 7,922; short σL = 71.007; left σ(z+L) = 1,993.407; cost = 71.007 × $300 + 1,993.407 × $3 = $27,282`	normal demand, one-month holding (illustrative)	$27,282

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
5	Buy at p95	`z = 1.6450: Q = 6,000 + 1.6450 × 1,500 = 8,468; short σL = 31.328; left σ(z+L) = 2,498.828; cost = 31.328 × $300 + 2,498.828 × $3 = $16,895`	normal demand, one-month holding (illustrative)	$16,895
6	Buy at p99 (CR)	`z = 2.3301: Q = 6,000 + 2.3301 × 1,500 = 9,495; short σL = 5.027; left σ(z+L) = 3,500.146; cost = 5.027 × $300 + 3,500.146 × $3 = $12,009`	normal demand, one-month holding (illustrative)	$12,009
7	Buy at p99.9	`z = 3.0900: Q = 6,000 + 3.0900 × 1,500 = 10,635; short σL = 0.416; left σ(z+L) = 4,635.416; cost = 0.416 × $300 + 4,635.416 × $3 = $14,031`	normal demand, one-month holding (illustrative)	$14,031
8	Accessory at the 70th	`Cu = 0.70 ÷ 0.30 × $3 = $7.00 per missed unit`	implied by the master's p70	Cu ≈ $7

Table 3a — pooling and the trigger (substituted).

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Pooling, k = 4, ρ = 0	`σ_pool = 500 × √(4 + 4·3·0) = 1,000.0; buffer = 2.33 × 1,000.0 = 2,330 vs 4 × 2.33 × 500 = 4,660`	month-1 σ = 500 per market (illustrative)	saves 50.0%
2	Pooling, k = 4, ρ = 0.3	`σ_pool = 500 × √(4 + 4·3·0.3) = 1,378.4; buffer = 2.33 × 1,378.4 = 3,212 vs 4 × 2.33 × 500 = 4,660`	month-1 σ = 500 per market (illustrative)	saves 31.1%
3	Pooling, k = 4, ρ = 0.6	`σ_pool = 500 × √(4 + 4·3·0.6) = 1,673.3; buffer = 2.33 × 1,673.3 = 3,899 vs 4 × 2.33 × 500 = 4,660`	month-1 σ = 500 per market (illustrative)	saves 16.3%
4	Pooling, k = 4, ρ = 1	`σ_pool = 500 × √(4 + 4·3·1) = 2,000.0; buffer = 2.33 × 2,000.0 = 4,660 vs 4 × 2.33 × 500 = 4,660`	month-1 σ = 500 per market (illustrative)	saves 0.0%
5	Trigger, no real shift (false alarms)	`p = 1 − Φ(2.0) = 2.28% per week per side; P(trigger within 52 weeks) = 2.55% per side → 0.051 false triggers per series-year (both sides)`	weekly noise 10% of curve (illustrative); consecutive-run recursion	0.051 / series-year
6	Trigger, true take-rate +10% vs curve	`p = P(week beyond ±20%) = 1 − Φ((0.20 − 0.10) ÷ 0.10) = 15.87% per week (one side); P(2 in a row within 4 / 12 weeks) = 6.8% / 22.0%`	weekly noise 10% of curve (illustrative); consecutive-run recursion	7% by week 4
7	Trigger, true take-rate +25% vs curve	`p = P(week beyond ±20%) = 1 − Φ((0.20 − 0.25) ÷ 0.10) = 69.15% per week (one side); P(2 in a row within 4 / 12 weeks) = 77.3% / 99.3%`	weekly noise 10% of curve (illustrative); consecutive-run recursion	77% by week 4
8	Trigger, true take-rate +40% vs curve	`p = P(week beyond ±20%) = 1 − Φ((0.20 − 0.40) ÷ 0.10) = 97.72% per week (one side); P(2 in a row within 4 / 12 weeks) = 99.8% / 100.0%`	weekly noise 10% of curve (illustrative); consecutive-run recursion	100% by week 4

Table 3 — after: the metrics, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Install delays from stockouts	3% of installs (baseline)	≈ 0.08% at the p99 buy	illustrative
2	First-quarter expected cost	$58,234 (p79)	$12,009 (p99)	newsvendor, illustrative
3	Buffer for 4 markets (independent)	4,660 units unpooled	2,330 pooled (−50%)	toolkit, illustrative
4	Re-forecast detection of a +25% shift	quarterly review	77% within 4 weeks	design arithmetic

STEP	METRIC	BEFORE	AFTER	BASIS
5	Owner of the forecast number	Planning	Planning (unchanged); I own equation, measurement, triggers	master honest line

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Reschedule cost avoided	`2,000 × (3% − 0.0838%) × $300 = $17,497/month`	p79 → p99 first buy	≈ $209,967/yr per market
2	Holding cost added	`p99 leftover 3,500 × $3 = $10,500 (one month)`	newsvendor row	$10,500
3	First-quarter cost difference	`$58,234 − $12,009 = $46,225`	expected cost, p79 vs p99	$46,225 per market per quarter
4	Stranding avoided (master)	`20% × $500K = $100,000`	held central	≈ $100,000
5	Master's annual spine	`$216,000/yr + $100,000 one-time`	illustrative; never a claim	design arithmetic

SOLUTION FLOW — THE FORECAST-TO-BUY CHAIN (PROPOSED)

```
[Build plan] --milestones--> [Sites passed] --adoption curve x marketing--> [Install demand]
      --kit requirement at finished-kit grain--> [Need by SKU x week, as PIRs]
      --MRP (measured lead times, confirmed dates)--> [Planned orders -> POs]
      --ASN--> [Central 3PL pool] --STOs as sell-through proves the curve--> [Markets]

First buy: Q = mu + z*sigma, z = PhiInv(Cu/(Cu+Co)) ; central, pooled
Trigger: |take-rate / curve - 1| > 20% for 2 consecutive weeks -> new forecast version
Weekly: MAPE and bias per SKU x market x week; bias sign before magnitude
```

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Cost of a missed install (Cu)	$150 → CR 0.9804	$300 → CR 0.9901	$600 → CR 0.9950
Demand CV (first buy sized for 25%)	CV 15% → surplus	CV 25% → 5.0 short	CV 35% → 42 short, 4.8% risk
Cross-market correlation ρ (k = 4)	0 → 50% saved	0.3 → 31.1%	0.6 → 16.3%
Trigger: weekly noise (true shift +25%)	5% → fires fast	10% → 77% by week 4	15% → slower

TOTAL IMPACT STATEMENT — SAY IT LIKE THIS

"This is a design, not a run record: I have not owned a launch forecast end to end, and the forecast number belongs to Planning. What I own is the equation, the measurement and the triggers. A missed install costs about three hundred dollars and a unit held a month about three, so the critical ratio is point nine nine and the first buy sits at the ninety-ninth percentile of the first quarter's demand; held central it pools — half the buffer for four uncorrelated markets, about thirty percent if they share a correlation of point three, which I would measure. A take-rate outside plus or minus twenty percent for two weeks forces a new forecast. The dollars — about two hundred sixteen thousand a year per market and a hundred thousand of stranding avoided — are the master's illustrative arithmetic, never a result."

If challenged — the full answers

Did you run it? “No — a design engagement; Planning owns the forecast, I own the equation, the measurement and the triggers.” Is the CV real? “Illustrative; the buy is re-sized on the first weeks’ observed spread.” Is that Google Fiber? “The master’s design engagements are Elementum client work; I would name the client only if confirmed.”

VERIFY-WITH-RAJESH

BEHAVIORAL PACK NEW — FOUR QUESTIONS THIS STORY ANSWERS, FOUR SEPARATE 90-SECOND ANSWERS (EACH FROM A DIFFERENT MOMENT OF THE STORY)

Q1 Tell me about a time you learned a new method to solve a problem. LEARN AND BE CURIOUS

Open (first two sentences): I took the newsvendor model from my MIT MicroMasters coursework and applied it to a launch problem — and I label it as the toolkit.

STAR (≈90 s): Situation: a new-market build with no demand history. Task: design the first buy. Action: Cu ≈ $300 for a missed install, Co ≈ $3 a month for a unit held, critical ratio 0.990, so the 99th percentile of first-quarter demand for the core unit and the 70th for lower-cost accessories. I then stress-tested it: if the true CV is 35% rather than 25% the shortfall chance goes from about 1% to 4.8%, which is why the trigger exists. Result: a design with arithmetic, not a run record.

Land this number: CR 0.990; z 2.33; Q = 9,495 on a 6,000 mean. · **Pivot to NACF:** A new FC or product launch at NACF is the same critical-ratio problem. · **Do NOT say:** Do not say I ran the launch; do not present the CV as data.

Q2 Tell me about a time you designed for scale beyond the immediate problem. THINK BIG

Open (first two sentences): I designed the launch chain as a template for market N+1, not a one-off for market N.

STAR (≈90 s): Situation: every market launch repeats the same chain — build plan, adoption curve, requirement, supply. Task: a design that a second and third market can reuse. Action: a stock-and-flow map, invariants — demand enters planning once, lead times are measured distributions, need floors with hold-until dates — and a weekly MAPE/bias loop. Result: a template; the forecast stays with Planning.

Land this number: One chain, three books of record, five invariants. · **Pivot to NACF:** A reusable placement template for each new NACF node. · **Do NOT say:** Do not claim a deployed template.

Q3 Tell me about a decision you made with very little data. ARE RIGHT, A LOT

Open (first two sentences): With no local history, the right question was not “what is demand” but “what does being wrong cost on each side.”

STAR (≈90 s): Situation: maximum uncertainty at launch. Task: first buy. Action: price both errors, buy to the critical ratio, hold it central so uncertainty pools, and write the trigger that proves the curve wrong fast: ±20% for two weeks. The trigger catches a true 25% shift within four weeks 77% of the time and false-fires about once every 20 series-years. Result: a decision with its own error rates.

Land this number: 77% detection by week 4 at +25%; 0.051 false triggers per series-year. · **Pivot to NACF:** Placement under uncertainty: price both errors, then set the trigger. · **Do NOT say:** Do not quote the weekly noise (10%) as measured.

Q4 Tell me about a time you put the end customer first in a supply decision. CUSTOMER OBSESSION

Open (first two sentences): The metric was install delays caused by stockouts — a customer waiting for a technician.

STAR (≈90 s): Situation: a missed install means a re-roll and deferred revenue. Task: make the stockout the thing the whole chain is measured on. Action: the primary metric joined reschedule reasons to the supply view; need floors so one market could not starve another’s launch; a governed screen with a reason code instead of an email. Result: design target zero delays caused by stockouts in the first 90 days.

Land this number: Target 0 delays in 90 days; ≈$300 per missed install (model). · **Pivot to NACF:** The NACF customer is the promise date; same joined-metric discipline. · **Do NOT say:** Do not claim installs were delivered.

SAME STORY, THREE ANGLES NEW — THREE DIFFERENT OPENERS, HEADLINE METRICS AND LPS FROM THE SAME FACTS

(I) DATA / ANALYTICAL

LP: Dive Deep; Are Right, A Lot

Open: "A 3% reschedule rate tells you the baseline was a 79th-percentile buy."

Headline metric: CR 0.990; p99 buy 9,495; cost $12,009 vs $58,234

- L(z) = 0.12 → z ≈ 0.8.
- Expected cost curve is flat near the optimum, steep to the left.
- CV 35% turns a 1% risk into 4.8%.
- All illustrative.

(II) CONFLICT / INFLUENCE / BACKBONE

LP: Have Backbone

Open: "Demand enters planning exactly once — manual loads beside the engine are blocked."

Headline metric: one engine, one demand path; floors with hold-until dates

- A floor breach is a governed screen with a reason code.
- One market cannot starve another's launch.
- A borrowed adoption curve is a stop-the-line item.
- Design stance, not a run record.

(III) FAILURE — LEARNING — WHAT I WOULD DO DIFFERENTLY

LP: Learn and Be Curious

Open: "I have not owned a launch forecast end to end."

Headline metric: pooling saves 31% at ρ = 0.3, not 50%

- Measure ρ on analog markets before quoting a saving.
- The forecast belongs to Planning.
- The toolkit is labeled.
- VERIFY-WITH-RAJESH client naming.

TRAP DRILLS NEW — THE THREE NASTIEST FOLLOW-UPS A STATISTICALLY RIGOROUS INTERVIEWER THROWS

T1 "Why the 99th percentile for the first buy — is that not wasteful?"

The numbers: CR = 300 ÷ 303 = 0.9901; z = 2.330; p99 buy 9,495: cost $12,009; p79 buy 7,200: $58,234; leftover 3,500 units × $3 = $10,500.

Say exactly: "Because a missed install costs a hundred unit-months of holding: at the ninety-ninth percentile the expected first-quarter cost is about $12 thousand against $58 thousand at the seventy-ninth, and the leftover — about thirty-five hundred units — is not waste, it is next quarter's demand."

T2 "Does the pooling benefit survive correlated markets?"

The numbers: k = 4: ρ = 0 → saves 50%; ρ = 0.3 → 31.1%; ρ = 0.6 → 16.3%; ρ = 1 → 0%.

Say exactly: "Only partly — half the buffer at zero correlation, about thirty-one percent at a correlation of point three, sixteen at point six; new markets share a product and a campaign, so I would measure it on analog markets before promising any number."

T3 "Your trigger is ±20% for two weeks. What are its false alarms and its power?"

The numbers: Weekly noise 10% (illustrative): no shift → 0.051 false triggers per series-year (both sides); true +25% → 77% within 4 weeks; +40% → 100%; +10% → 22% within 12 weeks.

Say exactly: "With ten percent weekly noise the trigger false-fires about once in 20 series-years, catches a true twenty-five percent shift within a month about 77 times in a hundred, and is nearly blind to a ten percent bias — which is why the bias sign publishes weekly beside it."

Question bank — likely questions for this interviewer, with a one-line answer plan

Behavioral and functional questions a Placement Analytics manager is likely to ask (rows 13–27 are new: the statistical questions the new primaries answer). Each plan points at a packet story or a named backup in the master packet; stories allocated to other interviewers are pointers only.

#	LIKELY QUESTION	ANSWER PLAN (ONE LINE)	STORY
1	**Walk me through how you improved forecast accuracy.**	S6 pitch — honest supply definition first, MAPE/bias at the decision grain, waves by trust; 70 → 85% on scoped class-A SKUs; planners owned the forecast, I owned its measurement.	S6
2	**Tell me about a time you used data to change an inventory policy.**	S8 pitch — brochure → measured lanes, p99 promise, 99% bar, 580K units / ~$1.5M out with zero stockouts.	S8
3	**How do you decide where / how much safety stock to hold?**	Two error signals measured at the grain; cost asymmetry sets the percentile; release only by signed rule with a watch; fat tails keep buffer.	S8 → S6
4	**What is the softest assumption in your biggest result?**	S6: the expedite count (60 × $5K). S8: the late-arrival share. Say how each would be firmed from a ledger.	S6 / S8
5	**How do you measure lead-time performance?**	Lead-time accuracy as the master defines it = 1 − |actual − promised| / promised against a per-lane p99 promise; per shipment that cannot reach 99% against a p99 promise, so say which reading (coverage, or re-measured p99 within 1%) before quoting a tolerance VERIFY-WITH-RAJESH; drift flag and refresh cadence.	S8
6	**Tell me about a time a stakeholder wanted a number that looked better.**	Planning's request to count unfirmed MRP orders as supply — refused; released planned orders only.	S6
7	**How did you handle a dependency that slipped (MPN mapping)?**	Escalated to the sponsor as a re-sequenced date with the coverage number attached; made MPN a standing metric rather than a task.	S6
8	**How would you decompose a network placement problem (e.g., inbound placement cost vs. speed)?**	Master §3.99 opening: book of record and metric → stocks and flows → broken invariant → design → sequence; then lead-time and forecast error at the lane × node grain as the two levers.	Master §3.99
9	**How do you validate a model before the business acts on it?**	Parallel run against the source (daily reconciliation to SAP; manual sample per cohort); a published gate; the old process stays alive until the match holds.	S6 (S10 pointer — Josyula's)
10	**What is your quantitative background?**	MIT Supply Chain MicroMasters + Supply Chain Network Design certificate — acquired to design what I had been implementing; the formulas are that toolkit, labeled. Never "I build models for a living."	Master §4.1 toolkit line
11	**Tell me about a time you improved a process end to end (Plan → Deliver).**	S6 as the Plan redesign (definition → gate → alert → release rule) with S8 as the Source/Deliver parameter feeding it; the two programs stay separate in dollars.	S6 + S8
12	**Another example of Dive Deep?**	Pointers only: S10 (Austria — bar raiser's) and S7 (phantom math — unallocated; no BOM-explosion content). If pressed, S7 at the level of "six sites, three waves, five months, zero auto-loaded revision overlaps."	S7 pointer

#	LIKELY QUESTION	ANSWER PLAN (ONE LINE)	STORY
13	**How do you know the lead-time distribution you measured is the right one — n, window, interval?**	S8a: ~400 shipments on the busy lane; the ranked p99 with its order-statistic interval; bell-curve p99 30.3 holds 96.5%, ranked p99 34 holds 99%; thin lanes print the interval or pool by cohort VERIFY-WITH-RAJESH NEW	S8a
14	**Planned vs actual lead time — how exactly was the plan wrong?**	S8a: plan 18 d vs mean 21 d (t = 15 on the 3-day bias); ERP σ 8 vs measured 4; tail 16 days short at p99 (34 vs 18) — wrong on location, spread and tail (illustrative lane) NEW	S8a
15	**How do you set safety stock and the service level?**	S8b: two terms — cover to the p99 lead time plus demand cover; critical ratio 0.99; lane A 12,937 → 8,102 units, lane B 5,238 → 6,621 (+1,383); 580K net is the record NEW	S8b
16	**How do you pick an alert threshold — precision, recall, and the cost of a false alarm?**	S6: alert at DoC ≤ lane p90; on an illustrative lane precision 71.2%, recall 98.6%; p99 trades twelve points of precision for about one of recall; cost $12,840 vs $8,913 at $60 / $5,000 NEW	S6
17	**How do you know it was your change and not seasonality?**	S8c: held-out quarter; paired old-vs-new plan on the same shipments (22 vs 175 late of 2,500); control lanes deferred a quarter if the record has them VERIFY-WITH-RAJESH; one draw, so rolling origin is the upgrade NEW	S8c
18	**What is the uncertainty on a result you are about to act on?**	S8c: 22 late of 2,500 → 99.1%, Wilson [98.7, 99.4]; z vs 96.5% = 7.1; 0 stockouts in 1,950 lane-weeks bounds the rate below 0.154% NEW	S8c
19	**Which of 1,000 lanes do you keep, and by what criteria?**	S9: spend Pareto + four-factor lane scoring + EDI survey; 597 lanes = 80% of spend first; ~400 deferred (~20%) on the same gate NEW	S9
20	**How would you design an estimated-delivery-date / promise policy?**	S19: promise at b = k·σ with k = 1.645 for a 95% floor; accuracy pinned on every cohort, speed floats; fast-promise share 7.6% → 39.6%; re-solve k per regime NEW	S19
21	**A headline metric is green — how do you check it?**	S19: headline 95.8% hid Φ(5.0) vs Φ(0.69) = 75.4% on the wide cohort; S20: raw +0.8 pt vs mix-adjusted −1.0 pt — publish the adjusted twin beside the raw NEW	S19 / S20
22	**Design a weekly business review for a delivery experience.**	S20: 7 outputs over 10 inputs and one joint headline; factor math names the owner in minutes; hard floors beside the headline; pre-wired reds NEW	S20
23	**How do you catch a degrading seller or carrier fast without false alarms?**	S20: Andon — n ≥ 30 floor plus a sustained signal; false-trip design bar < 5%; ~30 d → < 24 h (design, nothing in production) NEW	S20
24	**How would you test an incentive or contract change before launch?**	S21: replay a seller's orders under managed settings; c = 11 misses in 200 as the pre-agreed gate (illustrative); Wilson interval on the 85% handling adherence at n = 100: [76.7%, 90.7%] NEW	S21
25	**How would you forecast and place equipment for a new market with no history?**	E7: newsvendor with critical ratio 0.99 → z 2.33 → first buy 9,495 on a 6,000 mean; pooled central stock saves ~31% at ρ = 0.3; ±20% two-week re-forecast trigger; NACF INV-C for placement (illustrative; design, not run) NEW	E7

#	LIKELY QUESTION	ANSWER PLAN (ONE LINE)	STORY
26	**Which number across your stories is the softest?**	S19's ≈$13.3M/yr and S21's ≈$3.7M/yr are modeled; S9's −10% freight has no control group VERIFY-WITH-RAJESH; S8's accuracy definition VERIFY-WITH-RAJESH. Name it first, then say how I would firm it. NEW	S19 / S21 / S9
27	**How do you separate your contribution from the client's?**	S21: I claim the contract design and wave-one mechanics; the adoption curve is the client's. S19–S20 are engagement designs — nothing in production moved. NEW	S21 / S19 / S20

Cheat-numbers box — canon values with basis labels

Canon numbers for all ten primaries with their basis labels, from the master packet's §4.1 ledger; the last ten rows are new (S8a–E7).

METRIC	VALUE TO SAY	BASIS	NEVER
S6 forecast accuracy	70% → 85% on scoped class-A SKUs	record	claiming I owned the forecast
S6 safety stock	$2M released under the both-errors-improved rule	record, one-time	"$2M per year"; adding to S8
S6 recurring	≈$0.8M/yr (carry 0.2 · expedites 0.3 · planner capacity 0.3); range $0.5–1.2M	modeled	presenting as record
S6 timing / scope	shortage alert live in 3 months; about eight domains (user anchor); six sites; planner collaboration +50% (Apple F3)	record (domains: user anchor)	pasting "3 months" onto the six-site ingest (S7)
S6 alert rule	days-of-cover ≤ lane lead-time p90	record mechanism	—
S8 lanes / accuracy	200 lanes; 99% lead-time accuracy at the p99 promise	record	—
S8 release	580K units / ~$1.5M, zero stockouts in the watch window	record, one-time	"$1.5M to $2M"; annualizing it
S8 recurring	≈$0.6M/yr (carry 0.3 at a 20% all-in rate — S6/S2 use 10%, state it · expedites 0.3); range $0.3–1.4M	modeled	presenting as record
S8 unit value	≈$2.59/unit	derived from the record pair	—
Site count	"six sites"	record	"six NA sites"
Toolkit	MIT Supply Chain MicroMasters + Network Design certificate; formulas are illustrations	labeled	"I build supply chain models for a living"
S7 (pointer only)	six sites, three waves, 5 months; hardest site 6 weeks vs 3-week average	record	"500+ product families"; 60→95% inside S7; any BOM-explosion walk

METRIC	VALUE TO SAY	BASIS	NEVER
S8a — example lane	plan 18 d · actual mean 21 d · p99 34 d · n ≈ 400 · 240 of 400 (60%) slower than the brochure · normal p99 30.3 d holds 96.5%	illustrative (secondary-source lane)	presenting the lane as the program's data
S8b — safety-stock lanes	lane A 12,937 → 8,102 (SS 6,500 + 1,602 vs 9,437 + 3,500 pad); lane B 5,238 → 6,621 (+1,383); 150 × 4,500 − 50 × 1,900 = 580K	illustrative decomposition; the net 580K is record	saying the program "raised" fat-tail lanes as record VERIFY-WITH-RAJESH
S8c — held-out test	22 late of 2,500 → 99.12%, Wilson [98.67, 99.42]; 0 stockouts in 1,950 lane-weeks → < 0.154%	illustrative inputs	quoting window / quarter as fact VERIFY-WITH-RAJESH
S9 — EDI onboarding	1,000 asked → 597 = 80% of spend; completeness 60% → 95%; ≥95% valid-ASN gate held twice; freight −10% ≈ $2M in six months; ~200 next wave; remainder (~20%) deferred	completeness 60% → 95% and the ≥95% gate: record (Apple F1 / resume); 597 · 80% · $2M · 8× · twice-failed cohort: user anchor (GFiber v8 only)	annualizing the $2M; claiming −10% was causal without a control VERIFY-WITH-RAJESH
S9 — recurring	≈$0.4M/yr documentation labor	modeled	presenting as record
S19 — delivery promise	flat 1.10 d buffer → b = k·σ, k = 1.645; fast-promise share 7.6% → 39.6% at a held 95% floor; +$255K/wk ≈ $13.3M/yr	engagement model / modeled	the 97.8% variant and its $6.07M/wk — never claimed; any production result
S19 — regime drill	Q4 σ × 1.45 → accuracy 91.9% on a frozen dial; $12 breach cost vs $6.50 margin	model / drill	a live Q4 result
S20 — pre-purchase WBR	0.97 × 0.985 × 0.996 ≈ 95.2%; Promise Yield 41.5% = 43.6% × 95.2% (four-quarter target 50%); SE carrier 82% → accuracy 93.6%; ≈$0.58M per caught episode; false-trip bar < 5%; ~30 d → < 24 h	illustrative sample / modeled / design	any live Andon result — design engagement, nothing in production
S21 — managed shipping	enrolled ~38–42% stalled; 85% handling adherence; ≈$3.7M/yr per +10 pts of enrolled GMV; claim = contract design + wave-one mechanics	modeled	owning the adoption curve; presenting $3.7M as record
E7 — new-market buy	Cu ≈ $300, Co ≈ $3 → CR 0.99 → z 2.33; ±20% two-week trigger; $216K/yr per market + $100K stranding	illustrative; design, not run	saying it ran; naming the client unless confirmed VERIFY-WITH-RAJESH

Never-say, one glance before the call.

- Never add $2M (S6) and ~$1.5M (S8) into one number; never "$1.5M to $2M."
- Never "six NA sites" — "six sites." Never paste S6's "3 months" onto the six-site ingest.
- Never claim ownership of the demand forecast or the distributions — measurement, definitions, rule and policy were mine.

- Never present the safety-stock formula as a program artifact; MRP math at finished-goods grain only — no BOM explosion.
- Never present planner capacity as cash — time redeployed, not headcount removed.
- S10 (Austria) is the bar raiser's; S11/S12, S2/S18, S1/S3 belong to Tripathy, Goforth and Lan — pointers only here.

Backup bench — use only if a primary doesn't fit

Three fallbacks for an analytics manager: two master-packet backups plus one doc-derived Flexport micro-story — S4 (Sephora — the in-transit promise rule I got wrong; the failure / Are Right, A Lot question, promise math at lane σ) and S7 (Elementum — a contract manufacturer's planning data made safe to plan on, finished-goods grain only; Learn & Be Curious by math, not meetings); the doc-derived third is the FFA Asia latency investigation from the Flexport program record (Dive Deep on production evidence; record-from-docs labels, facts identical to the same bench in Josyula's packet). S9 (the 1,000 → 597 EDI story) was promoted to a full primary above. Tell the ten primaries first.

Bench discipline. The ten primaries above are the stories to tell first. Reach for a bench story only when the question genuinely does not fit a primary, or when the interviewer asks for "another example" on an LP already spent. Each entry is a 60-second pitch, a compressed STAR, one results line and two probes — enough to answer and stop; no full probing bank or derivation. Where a bench story is another interviewer's primary, the red note says so: use it only if the question demands it, and keep the facts identical to that packet.

BACKUP — ONLY IF ASKED S4 — Sephora S/4HANA — the in-transit promise rule I got wrong, fixed through the signed policy, not a side configuration

LPs this backup can serve: Are Right, A Lot (the failure question) · Customer Obsession (backup) · Earn Trust (owning the miss) · Learn and Be Curious — the designated policy-failure story

Basis. The v1 rule was mine; the indictment came from my own program's reports. Lane σ ≈ 0.3 day and the ~0.49-day window are the record's promise math; the record carries no lane counts and no dollar for the conversion lost while I was wrong — I will not invent the loss figure.

60-SECOND PITCH — STOP ON THE PRIMARY METRIC

Situation. My first ISM ruleset barred every channel from promising units in transit; the Aging In-Transit report showed dotcom starved of fast movers one day from the building. **Task.** Correct my own policy without weakening oversell protection, through the same three signatories. **Action.** Discovery: conversion-loss evidence from the aging and replenishment reports — the entry bar to reopen the policy; I stated that the v1 rule was mine. Plan & Design: promise math — lane σ ≈ 0.3 day, a ~0.49-day window ≈ 95% coverage; Promisable = in-transit × 1[ETA ≤ window] × 1[on-time ≥ floor]; Aging In-Transit as the kill switch; both blanket options rejected in writing. Build & Test: back-test against receiving history; four regression cells added to the node × channel matrix. Cutover: released on the normal monthly cadence as a signed FSD change, lane by lane — no hotfix, no side configuration. Hypercare: kill switch armed; never fired. Lesson: both sides of a rule get a number before it ships. **Result.** Primary metric: sellable units on qualifying in-transit lanes — starved → restored inside a per-lane promise window, oversell increase = zero, kill switch never fired. ≈$0.5M/yr modeled margin recovered — the record has no dollar for the conversion lost while I was wrong, and I will not invent one.

COMPRESSED STAR

- **S —** v1 of my own ISM ruleset: no channel could promise in-transit units — safe-feeling, and starving dotcom of fast movers reliably one day from the building.
- **T —** Fix my own signed policy without weakening oversell protection; take the miss back through the same three signatories.
- **A —** Evidence pack from Aging In-Transit and Replenishment; reframed as promise math (σ ≈ 0.3 d → ~0.49-d window ≈ 95%); rule with on-time floor and kill switch; back-test against receiving history; four regression cells; released lane by lane on the monthly cadence as an FSD change.

- **R —** Starved lanes restored inside the window; oversell increase = 0; kill switch never fired; re-signed by the same three signatories; lesson institutionalized — the Locus 98% gate (S2) and the 0.5% tolerance (S18) were set from data before the event.

RESULTS LINE

Sellable units on qualifying in-transit lanes starved → restored inside a back-tested ~0.49-day window (record) · oversell increase = 0; kill switch armed, never fired (record) · four regression cells added (record) · released as a signed FSD change on the normal cadence, no hotfix (record) · ≈$0.5M/yr modeled margin recovered (inputs illustrative).

THE MATH — STEP-BY-STEP DERIVATION

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	The v1 rule	`Promisable = 0 for ALL in-transit inventory`	equivalent to claiming σ → ∞ or on-time rate → 0 — infinite variability (record)	everything in transit hidden
2	One concrete lane	`Promisable = 120 × 0 = 0`	lane with InTransit = 120 units, ETA 0.4 day away (illustrative)	120 sellable units hidden
3	Across qualifying lanes	`≈300 fast-mover units/day × 0 promisable`	illustrative volume	≈300 units/day sat unsellable one day from the building
4	What starving costs (one SKU)	`100 × 60% × $20 = $1,200/day`	100 units one day out; 60% would convert; $20 margin (illustrative, not program data)	$1,200/day under-sell
5	The ignored other side	`100 × (1 − 0.97) = 3 late units; 3 × $15 = $45/day`	on-time rate 97%; $15 expedite (illustrative)	$45/day over-sell exposure — vs $1,200: the “safe” rule priced one side only

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Measure lane variability	`σ = 0.3 day`	trailing receiving history (record)	σ = 0.3 day
2	Choose coverage	`z at 95% = 1.645`	normal approximation on lane transit (toolkit label)	z = 1.645
3	Promise window	`w = z × σ = 1.645 × 0.3 = 0.4935`	rows 1–2	w ≈ 0.49 day
4	Coverage check	`Φ(w / σ) = Φ(0.49 / 0.3) = Φ(1.63) ≈ 0.95`	share of arrivals inside the window	≈95% covered
5	Corrected rule	`Promisable = InTransit × 1[ETA ≤ w] × 1[OTR ≥ floor]`	OTR = on-time rate over trailing receipts; floor = per-lane admission threshold, 95% here (floor illustrative)	lane by lane, not all-or-nothing
6	Lane that qualifies	`ETA 0.4 ≤ 0.49 → 1; OTR 97% ≥ 95% → 1; Promisable = 120 × 1 × 1 = 120`	the Table 1 lane, re-evaluated (ETA and OTR illustrative)	its 120 units become promisable
7	Lane that fails	`ETA 1.2 > 0.49 → 0; Promisable = 80 × 0 = 0`	a slower lane with 80 units in transit (illustrative)	stays at 0 — correctly out
8	Sample-size gate	`n = z²p(1−p)/e² = 3.84 × 0.95 × 0.05 / 0.05² = 3.84 × 0.0475 / 0.0025 ≈ 73`	OTR estimated within ±5% at 95% CI (illustrative)	a lane qualifies after ~73 receipts

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
9	Kill switch, values in	`trigger = 2 × p90 = 2 × 2.0 = 4.0 days; any unit in transit > 4.0 days → lane out`	lane p90 = 2.0 days (illustrative); armed, reviewed weekly by Inventory Control (record)	never fired (record)
10	Back-test	`rule replayed against receiving history; 4 regression cells`	before release (record)	no oversell in the back-test

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Sellable units on qualifying in-transit lanes	0	≈300 units/day restored inside the window	record mechanism; volume illustrative
2	Promise window	none — blanket exclusion	w ≈ 0.49 day at ~95% cover	record (promise math)
3	Oversell increase from the window	—	0	record
4	Kill switch	not armed	armed, never fired	record
5	Rule changes after	ad hoc	same 3 signatories, back-test + matrix regression	record — both sides priced from then on

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Would-be sales	`300 × 60% = 180 sales/day`	units restored (illustrative) × conversion (illustrative)	180 sales/day
2	Truly lost without the fix	`180 × 40% = 72 sales/day`	40% lost-sale share — the rest would have waited (illustrative)	72 lost sales/day
3	Margin recovered	`72 × $20 = $1,440/day`	$20 unit margin (illustrative)	≈$1,440/day
4	Annualized	`$1,440 × 365 = $525,600`	modeled; the mechanism is record	≈$0.5M/yr
5	Cost while v1 stood	`no dollar in the record — not claimed`	record	not claimed

TWO PROBES

Why not just hotfix it — you knew it was wrong?

Because the error was in the policy, so the fix had to be too — in the governed artifact, with regression, through the same signatures. A side configuration would have fixed the symptom and left the policy lying about what it allowed.

What did the miss cost?

The record carries no dollar for the conversion lost while v1 stood, and I will not invent one. What I can say is the mechanism: fast movers reliably one day from the building were unsellable on dotcom until the window existed; the ≈$0.5M/yr recovered is my model on illustrative inputs, labeled.

Canon numbers (basis labels): Lane σ ≈ 0.3 d; ~0.49-d window ≈ 95% coverage (record promise math) · oversell increase = 0 (record) · 4 regression cells (record) · kill switch never fired (record) · same three signatories re-signed (record) · ≈$0.5M/yr (modeled). Never a lane count; never a dollar for the loss while wrong.

BACKUP — ONLY IF ASKED S7 — Elementum — making a contract manufacturer's planning data safe to plan on: six sites, three waves, five months, zero auto-loaded revision overlaps

LPs this backup can serve: Learn and Be Curious (primary — learned the CM's data by math, not meetings) · Dive Deep · Earn Trust (external partner)

Basis. I owned the ingest requirements, the reconciliation gate, the wave plan and the weekly Flextronics call; engineers built the normalization layer and quarantine to the spec; the commercial relationship belonged to the customer's procurement — my leverage was evidence. The $1.5M / 580K belong to the p99 program this backbone enabled (S8). Finished-goods grain only here; no tolerance value — the record does not carry one.

60-SECOND PITCH — STOP ON THE PRIMARY METRIC

Situation. Flextronics supplied the planning data our component-demand visibility depended on, and it carried two traps documentation never confesses: pass-through assemblies that double-time demand if loaded as stocked, and overlapping revisions that rewrite history if you auto-load one. Six site systems carried six definitions of yield, lead time and order status. **Task.** I owned the ingest requirements, the reconciliation gate, the wave plan and the weekly Flextronics call — with no commercial leverage; evidence was my only lever. **Action.** Discovery: sampled finished goods and reconciled the CM's planning data against its own MRP — the trap signature found by math, named in a discovery memo. Plan & Design: an explicit marker for pass-through items; an effective-date quarantine with human disposition — never auto-load; one supply equation (on-hand + production plan + released planned orders) signed by customer planning. Build & Test: mapping tables owned by named site super-users; a per-site reconciliation report as the go-live gate. Cutover: three waves — two cleanest high-volume sites, then three on parameterized maps, then the hostile legacy ERP by snapshot-diffing at six weeks against a three-week average, priced up front. Hypercare: the weekly call left standing — it had become theirs. Lesson: reconcile to the source's math, not its documentation. **Result.** Primary metric: contract-manufacturer sites with planning-grade data — 0 → 6 in three waves and five months, zero auto-loaded revision overlaps. ≈$0.3M/yr modeled — the six sites and zero overlaps are measured; the dollars are my model; the $1.5M belongs to S8.

COMPRESSED STAR

- **S —** A contract manufacturer's planning feed with two silent traps; six sites, six definitions; one hostile legacy ERP (flat files, no change-data-capture); no commercial leverage.
- **T —** Own ingest requirements, the reconciliation gate, the 2/3/1 wave plan, and chair the weekly Flextronics call.
- **A —** Found the traps by sampling finished goods against the CM's own MRP; designed the two mechanisms that made the traps impossible rather than policed (explicit marker; effective-date quarantine, human disposition); reconciliation report as the per-site gate, not a date on a slide; wave 3's six weeks priced to leadership as the plan, not a slip; made the weekly call the CM's own protection against blame for misses its feed didn't cause.
- **R —** Planning-grade sites 0 → 6 in 3 waves / 5 months; zero auto-loaded overlaps ever; phantom double-timing eliminated at source; backbone handed to the 200-lane program (S8).

RESULTS LINE

CM sites with planning-grade data 0 → 6 in three waves / five months (record) · auto-loaded revision overlaps = 0, ever (record) · hardest site 6 weeks vs the 3-week average, priced up front and absorbed in plan (record) · ≈$0.3M/yr (modeled — reconciliation labor, expedites fired at false shortages, overlap rework); the record has no dollar for this story; the $1.5M belongs to S8.

THE MATH — STEP-BY-STEP DERIVATION

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Planning-grade CM sites	`0 of 6; manual BOM-vs-MRP reconciliation at every site`	record	0 of 6
2	Manual recon burn	`6 h/wk × 6 sites = 36 h/wk`	modeled	36 h/wk of reconciliation
3	What MRP computes (finished-goods grain)	`NetReq(FG, t) = GrossReq − OnHand − SchedReceipts`	the netting identity; walk below at FG grain only (illustrative)	substituted in rows 4–5
4	Clean row	`NetReq = 500 − 150 − 200 = 150`	Gross 500; on-hand 150; receipts 200 (illustrative)	NetReq = 150; need-date = due − LT_FG
5	Distorted row — phantom FG record	`NetReq = 600 − 150 − 200 = 250; false shortage = 250 − 150 = 100`	a phantom/stale finished-goods record inflates gross requirements by 100 (illustrative)	an expedite fires on 100 units never needed
6	How often	`~5/site/mo × 6 sites × 12 mo = 360 false shortages/yr`	modeled count	360/yr
7	Timing corruption	`the same stale record pulls the need-date a lead-time early`	record mechanism	planners chase demand that was never real
8	Revision overlaps	`two revisions both partially true in [d0, d1]; ~24/yr`	auto-loading would rewrite demand for orders released under the prior revision (record rule; count modeled)	~24 history-rewrite risks/yr

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Explicit marker	`distorted row reconciled: NetReq = 500 − 150 − 200 = 150`	the phantom record carries an explicit marker; it no longer inflates gross (record mechanism)	NetReq = 150 — matches the site's own MRP
2	Per-site gate	`count_model vs count_MRP on sampled finished goods must match`	the reconciliation report is the go-live gate, not a date on a slide (record)	a site opens on a matched report
3	Quarantine	`overlaps held for human disposition per order/effectivity`	record rule	auto-loaded overlaps = 0 — ever
4	Hostile flat-file site	`completeness = rows received / expected; a 40%-rows file would read as 60% deletions → blocked`	snapshot-diffing with a completeness flag (record mechanism)	partial files never consumed
5	Wave plan	`W1: 2 × 3 = 6 wk; W2: 3 × 3 = 9 wk; W3: 6 wk; 6 + 9 + 6 = 21 weeks`	hostile site at 6 wks vs the 3-wk average, priced up front (record)	≈5 months for six sites
6	Recon labor after	`6 → 1.5 h/wk per site — disposition queue only`	modeled	−4.5 h/wk per site

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Planning-grade CM sites	0 of 6	6 of 6, in 3 waves ≈ 5 months	record
2	Manual reconciliation	6 h/wk × 6 sites	1.5 h/wk × 6	modeled
3	Expedites on false shortages	~72/yr acted on	~0 — the marker removes the distortion	modeled
4	Auto-loaded revision overlaps	uncontrolled	0 — ever	record

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Reconciliation labor	`(6 − 1.5) = 4.5 h/wk; × 6 sites = 27 h/wk; × 48 wk = 1,296 ≈ 1,300 h; × $60 = $77,760`	modeled	≈$0.08M/yr
2	False-shortage expedites	`360 × 20% = 72 acted on; 72 × $3,000 = $216,000`	count from Table 1 row 6; premium benchmark $2–5K (modeled)	≈$0.2M/yr
3	Overlap rework avoided	`24 × 16 h = 384 h; 384 × $60 = $23,040`	the quarantine makes the error 0 by construction (modeled)	≈$0.02M/yr
4	Total	`0.08 + 0.2 + 0.02 = $0.3M`	the record has no dollar for S7; the $1.5M belongs to S8	≈$0.3M/yr

TWO PROBES

How did you get an external supplier with no obligation to care?

By making the weekly call theirs: it protected Flextronics from blame for misses their feed didn't cause. Procurement held the commercial relationship; my lever was the evidence in the discovery memo, confirmed by their own engineering.

Why three waves instead of one?

So one surprise could not spend six sites of credibility — the two cleanest high-volume sites first, three on parameterized maps second, the hostile ERP last with its six weeks priced up front. Speed was traded, never quality: a site went live off its matched reconciliation report, not a date.

Canon numbers (basis labels): 0 → 6 sites, 3 waves, 5 months (record) · zero auto-loaded overlaps (record) · 6 weeks vs 3-week average (record) · ≈$0.3M/yr (modeled). Never "six NA sites"; never "500+ product families"; 60 → 95% belongs to S9; the $1.5M / 580K belong to S8; no tolerance value.

BACKUP — ONLY IF ASKED Doc bench — Flexport FFA — the Asia latency investigation: a 21-second P95 traced to routing, decomposed to the layer, fixed in sequence (Dive Deep)

LPs this backup can serve: Dive Deep (primary — decomposition to the layer) · Deliver Results · Learn & Be Curious · Insist on the Highest Standards (a smoke-test protocol per change)

Basis. Doc-derived micro-story from the program record (the FFA Asia latency investigation, post-MVP 2022) — every figure is RECORD-FROM-DOCS: the investigation document, written when the FF App MVP had launched to 11 partners in 10 countries and 48 of 53 import partners (90.5%) had migrated. Program-lead voice: I owned the investigation, the decomposition and the fix sequence; infrastructure teams executed the WAF and CDN changes. Not in the master packet's S-numbering; supplements canon, never overrides it. The same bench appears in Josyula's packet — facts identical.

60-SECOND PITCH — STOP ON THE PRIMARY METRIC

Situation. Weeks after the FF App MVP launched to 11 partners in 10 countries — with 48 of 53 import partners already migrated — the monthly business review showed Asia page loads at a P95 of 21.19 seconds against 3.3 in the US. **Task.** Find the layer, not the anecdote, and fix it without a re-architecture in the middle of a live partner-facing launch. **Action.** I decomposed the problem before prescribing: static assets ran ~5s P95 in China against ~500ms in the US, and the app's domain had no geo-based DNS or reverse proxy — Asia traffic was riding the public internet across the Pacific; a double CDN sat on the static path. The fix was a sequence, not a project: enable the WAF, remove the double CDN (direct to S3), then a regional CDN proposal with a smoke-test protocol per change, then China tuning, then Asia tuning — each with a date and an owner. **Result.** Root cause isolated to routing — not the app, not the partners; two fixes shipped inside the investigation window and the regional plan scheduled with dates; and a standing rule imported into every later launch: the pilot's geography is a performance requirement, not a rollout detail.

RECORD-FROM-DOCS

COMPRESSED STAR

- **S —** Post-MVP, the MBR surfaced Asia P95 page load at 21.19s vs 3.3s in the US (17-day measurement window); 48 of 53 import partners (90.5%) already migrated — the app had to hold where the partners were.
- **T —** Isolate the layer causing Asia latency and sequence the fix set without destabilizing a live partner-facing launch.
- **A —** Split static from dynamic: static JS ~5s P95 in China vs ~500ms US; found no geo-based DNS / reverse proxy on the domain (public-internet routing) and a double CDN on static assets; sequenced WAF enablement → double-CDN removal (direct to S3) → regional CDN proposal → China tuning → Asia tuning, each gated by a smoke-test protocol with a named date and owner.
- **R —** Root cause isolated to routing; WAF and double-CDN fixes shipped inside the window; CDN / China / Asia work scheduled with owners; the investigation became the template for launch-geography checks.

RESULTS LINE

P95 page load 21.19s Asia vs 3.3s US (record-from-docs) · static ~5s China vs ~500ms US (record-from-docs) · 48 of 53 partners migrated = 90.5% (record-from-docs; canon's "48 of 53 within a month" — consistent) · two fixes shipped, three sequenced with dates (record-from-docs) · no post-fix latency figure exists in the record — never invent one.

THE MATH — STEP-BY-STEP DERIVATION

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Page-load P95 by region	`Asia = 21.19s; US = 3.3s; Others = 4.45s`	Datadog @view.loading_time, 04/24–05/10 window (record-from-docs)	Asia is the outlier

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
2	The gap factor	`21.19 ÷ 3.3 = 6.42`	row 1 (record-from-docs)	6.42× slower than the US
3	Traffic behind the number	`6.31 ÷ 2.19 = 2.88`	Asia 6.31k vs US 2.19k page views, same window (record-from-docs)	≈2.9× the US traffic riding the worst latency
4	Static-asset leg	`JS P95 = 5s China vs 500ms US; 5 ÷ 0.5 = 10`	static.flexport.com CDN behavior (record-from-docs)	10× gap on the static leg
5	Dynamic leg	`no geo-DNS / reverse proxy for trade.flexport.com → Asia GraphQL hairpins over the public internet`	infra review (record-from-docs)	routing penalty on every data call
6	Known defect on the static path	`double CDN in China — Cloudflare stacked in front of Tencent`	infra review (record-from-docs)	one avoidable hop

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Decompose before touching	`page load = static resources + GraphQL requests + JS rendering`	the metric's own definition (record-from-docs)	three legs, measured and owned separately
2	Step 1 — security gate first	`enable WAF for trade.flexport.com: China, then global`	incident-207 follow-up; done 2022/06/30 (record-from-docs)	shipped — fix 1 of 2
3	Step 2 — remove the double CDN	`Tencent CDN → direct to the S3 bucket; Cloudflare hop removed for China`	done 2022/06/24 (record-from-docs)	shipped — fix 2 of 2
4	Step 3 — static proposal, CN/Asia	`alternatives written, reviewed, signed off`	ETA 2022/07/15 (record-from-docs)	sequenced with a date
5	Step 4 — China tuning	`e.g. replicate static assets in-region`	ETA 2022/07/30; depends on step 4 (record-from-docs)	sequenced with a date
6	Step 5 — Asia tuning	`the same playbook beyond China`	ETA 2022/08/15 (record-from-docs)	sequenced with a date
7	Held in reserve	`global CDN for trade.flexport.com — built only if the metrics still demand it`	2022 Q3 or later, metrics-gated (record-from-docs)	no speculative spend
8	Verification per change	`2 user types × 2 instances = 4 smoke passes before + 4 after = 8`	login → workview → logout → re-login; internal SSO + partner users; US + China hosts (record-from-docs; the multiplication counts the checklist)	8 workflow passes around every change

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Root cause	one number — "Asia is slow"	static leg (10×) and dynamic routing isolated, each with an owner and a sequence	record-from-docs
2	Fixes	none	2 shipped (WAF; double-CDN removal); 3 sequenced with dates (07/15, 07/30, 08/15)	record-from-docs
3	Post-fix P95	21.19s	no post-fix figure exists in the record — never claimed	record-from-docs

STEP	METRIC	BEFORE	AFTER	BASIS
4	Spend discipline	—	global CDN gated on metrics, not built on speculation	record-from-docs

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	INPUTS (BASIS)	VALUE
1	Partner base exposed	`48 ÷ 53 = 0.9057 ≈ 90.5% of import partners already migrated when the gap surfaced`	migration tracker (record-from-docs)	90.5% of partners on the affected app
2	Excess wait served per window	`gap vs US = 21.19 − 3.3 = 17.89s; 6,310 × 17.89 = 112,886 partner-seconds; ÷ 3,600 ≈ 31.4 hours`	6.31k Asia page views in the 17-day window (record-from-docs); gap arithmetic illustrative	≈31.4 partner-hours of excess wait every 17 days
3	Dollar value of the wait	`no dollar in the record — not claimed`	record-from-docs	not claimed
4	Post-fix saving	`no post-fix latency figure exists → no savings chain exists`	record-from-docs	never invent one

TWO PROBES

How did you know it was routing and not the application?

By decomposition before remediation: the static/dynamic split put ~5s of the China time on assets the app server never touched, and the same assets served in ~500ms from the US — the code was constant, the path was not. The domain's missing geo-DNS / reverse proxy and the double CDN explained both halves of the gap without a single application change.

Why not just stand up a China region?

A region is a re-architecture with a compliance tail; the evidence said the bottleneck was routing and CDN topology, which fixes in weeks. The sequenced plan — WAF, double-CDN removal, regional CDN, tuning — bought most of the win at a fraction of the risk, and the smoke-test protocol meant each step was reversible.

Canon numbers (basis labels): 21.19s vs 3.3s P95 (record-from-docs) · ~5s vs ~500ms static (record-from-docs) · 48/53 = 90.5% migrated (record-from-docs) · 11 partners / 10 countries MVP (record — matches S12 canon) · fix sequence WAF → double-CDN → regional CDN → China → Asia with smoke tests (record-from-docs). Never: a post-fix latency number (none in the record); never present scheduled items as delivered.

VERIFY BEFORE YOU SAY IT NEW

Each line is a detail that is **not in the record**, or a number resting on an illustrative input; it carries VERIFY-WITH-RAJESH where it appears in a story. Tick it, or leave it out of the room.

EVERYTHING

- ☐ S19–S21 are DESIGN CASES from my Walmart-role prep — say “a design case I worked through for a marketplace delivery-promise role,” never “my client at Walmart” or “the engagement delivered.” E7: “Google Fiber” only if confirmed — otherwise “a broadband build-out client.”
- ☐ That none of S9, S19, S20, S21 or E7 is also planned as a primary for another interviewer — one question, one story across the loop.
- ☐ Every “illustrative” number is said with the word “illustrative” — the example lanes are a secondary source, not the program ledger.

S6

- ☐ How p90 was originally chosen for the alert (the precision/recall table is after-the-fact design arithmetic).
- ☐ How “demonstrably improved” was operationalized for the both-errors rule (the standard-error bar is my arithmetic, not the record).
- ☐ How large the MPN-mapping delay actually was.

S8

- ☐ Which definition of “99% lead-time accuracy” the program used — ratio, coverage, or p99-match — before quoting any tolerance.
- ☐ The thin-lane rule, the lane-cohort counts and the watch-window length (none is in the record).

S8A

- ☐ That the example-lane numbers (n ≈ 400, plan 18, mean 21, p99 34) are the ones I am comfortable quoting as illustrations.
- ☐ What the program actually did on thin lanes, and whether a quarterly cut of the +3-day bias was run.

S8B

- ☐ The 150 / 50 lane split and whether fat-tail lanes were “kept” (master) or “took stock in” (loop packet).
- ☐ The actual stakeholder dynamics behind the one-way-cut argument; whether a demand–supply correlation test was run; that the textbook form was my own starting point.

S8C

- ☐ Watch-window length; which quarter was held out, and whether it was a peak or a quiet quarter.
- ☐ Whether a control (deferred lanes) or a rolling-origin back-test existed; any pressure to release early.

S9

- ☐ The grain behind completeness 60% → 95% (event or shipment); the gate test sizes and whether the bar was an observed rate or a bound.
- ☐ Whether any control comparison was run for the −10% freight, and the base period behind “≈$2M in six months.” Cohort sizes are not in the record.

S19 / S20

- ☐ Any failure or live result beyond the stated drills — both are design engagements; nothing in production moved.
- ☐ The exact EWMA / CUSUM parameters of the Andon.

S21

- ☐ The order of discovery (funnel first, interviews second) and anything claimed beyond contract design plus wave-one mechanics.

E7

- ☐ Client naming; every CV, correlation and noise input is illustrative; the design was not run — say “I designed”, not “we ran”.

> **If you cannot tick it:** say “illustrative inputs, real outcomes”, give the record (200 lanes, 99%, 580K units / ~$1.5M, zero stockouts) and how you would firm the softer input. Never invent a window, a cohort count or a dollar.

NUMBERS I MUST NOT GET WRONG NEW

The canon numbers this packet uses, each with its basis word. Say the basis in the same breath as the number.

NUMBER	WHAT IT IS	BASIS	NEVER / CAREFUL
580K units / ~$1.5M	S8 — released with zero stockouts in the watch window; ≈$2.59/unit	record, one-time; $2.59 derived	never merged with the $2M into a range; never per year
≈$0.6M / yr	S8 — carry 0.3 at a 20% all-in rate (S6/S2 models use 10% — say which) + expedites 0.3; range $0.3–1.4M	modeled	not a result
200 lanes · 99% · p99	S8 — promise at p99; 99% lead-time accuracy gate	record	quote a tolerance only after naming the definition
70% → 85% · $2M	S6 — class-A forecast accuracy; safety stock released under the two-signal rule	record, one-time	never add to S8; never “I owned the forecast”
≈$0.8M / yr	S6 — carry 0.2 (10% on the $2M) · expedites 0.3 · planner capacity 0.3; range $0.5–1.2M	modeled	planner capacity is time, not cash
3 months · +50%	S6 — shortage alert live; planner collaboration up 50% (never “effort −50%”; the 8× adoption figure is S9’s user anchor)	record	never paste “3 months” onto the six-site ingest
1,000 → 597 = 80%	S9 — asked vs built first; remainder (~20%) deferred; ~200 next wave	user anchor (GFiber v8 only; Apple F1 says “a thousand lanes onboarded across 25 European locations”)	not “1,000 lanes live”
60% → 95% · ≥95% gate	S9 — completeness; valid-ASN gate held twice	record	grain of the 95% VERIFY-WITH-RAJESH
−10% ≈ $2M of freight spend in six months	S9 — freight spend (a different $2M from S6’s safety stock)	user anchor (GFiber v8 only), not annualized	no control group for causal claims VERIFY-WITH-RAJESH
1.10 d → b = k·σ, k = 1.645	S19 — flat buffer vs governed dial; fast-promise 7.6% → 39.6% at a 95% floor	design case — in the model (Solver recompute matches)	the 97.8% variant is never claimed
+$255K/wk ≈ $13.3M/yr	S19 — modeled value of the dial	modeled	never record; $12 breach vs $6.50 margin is the sensitivity
41.5% = 43.6% × 95.2%	S20 — Promise Yield on the docs' sample; target 50%	illustrative sample / design target	nothing in production moved
~30 d → < 24 h · < 5%	S20 — Andon detection-to-action; false-trip design bar	design	no live Andon result
~38–42% · 85% · ≈$3.7M/yr	S21 — stalled enrollment; handling adherence; per +10 pts of enrolled GMV	design case — prep estimates / modeled; never a Walmart actual	claim = contract + wave one only
CR 0.99 · z 2.33 · ±20%	E7 — newsvendor first buy and the two-week trigger; $216K/yr per market + $100K stranding	illustrative; design, not run	client name only if confirmed VERIFY-WITH-RAJESH
Six sites	every program	record	say it with no regional qualifier

Basis vocabulary. *record* — measured and signed in the program · *user anchor* — a number the candidate stated · *modeled* — my arithmetic on labeled inputs · *illustrative* — example inputs chosen to show the math · *design* —

specified, not run · *design case* — a case I worked through for interview prep (S19–S21): every number “in the model,” nothing delivered.

INTERVIEW-PREP PACKET 3 OF 5 · PER-INTERVIEWER · BUSINESS-PROCESS LENS · V2 — NINE PRIMARIES

Amazon NACF Supply Chain loop — Packet 3: Rocky Goforth

Amazon — Senior Supply Chain Manager, NACF Supply Chain (L6)

Rocky Goforth

Senior Manager, Infrastructure — NACF

Thursday, October 30, 2026 · 10:00 am PDT · 55-minute video interview

Strategy in one line. An infrastructure owner wants to know what happens when the plan meets the floor. Open with S2 (one comingle pool instead of two warehouses, a robotics ramp behind a published 98% gate that fired at 94, two go-lives with zero customer-facing incidents) and hold S18 (dual-DC WMS migration: 0.5% tolerance published before mock one, 7% → 1.8% → 0.3%, the RF-device miss owned) for the go-live-gone-wrong / Bias for Action question. Gates, invariants, triggers and hypercare numbers are the vocabulary; vendors configured, DC Ops ran the floor. **v2:** seven new primaries (U1–U7) re-cut the same Sephora node facts — matrix, profile, reserve, constraint, runbook, AFS control, issues log — each with its own math, behavioral pack, angle cards, trap drills and NACF bridge.

LP focus — my guess, not confirmed: Insist on the Highest Standards · Bias for Action · Deliver Results or Ownership. Amazon does not disclose the assignment; the guesses are reasoned from the interviewer's title and the JD in "Read me first" and should be held loosely. No interviewer biography is asserted anywhere in this packet — only title-based inference, labeled as such.

5-Minute Cram Sheet — Rocky Goforth NEW

Profile hooks (title-based inference — no biography asserted)

- **Senior Manager, Infrastructure.** Owns the physical and systems substrate: buildings, automation, WMS layer, capacity, launches, cutovers, peak readiness. His question is *what happened when the plan met the floor.*
- **His vocabulary:** dock, space, labor, throughput, node constraints, gates, rollback, freeze windows, hypercare exit — and physical truth vs system truth.
- **My moves:** open S2; name the gate that fired; put every dollar behind its basis word; end each story on one number, then one sentence to NACF inbound (doors × hours × unload rate · UPH · cube).
- **LP guess (unconfirmed):** Insist on the Highest Standards · Bias for Action · Deliver Results / Ownership — Dive Deep and Earn Trust are likely second-round.

The nine stories, in the order to reach for them

#	STORY	LPS	THE ONE NUMBER
1	**S2** · Utah DC comingle pool + robotics gate ELEVATED	Insist on the Highest Standards · Deliver · Backbone · Earn Trust	+15% processing efficiency, zero customer-facing incidents *(record)*
2	**U4** · Where the node's constraint bound NEW	Bias for Action · Frugality · Dive Deep · Earth's Best Employer	94 vs 98 → ~30% dial; ≈421 h vs ≈4,200 mis-picks *(modeled)*
3	**U5** · 343-task runbook, one irreversible instant NEW	Ownership · Deliver · Backbone · Dive Deep	343 tasks · ~815 h · 61 days; rollback never fired *(record)*
4	**S18** · WMS migration, two DCs; 0.5% tolerance ELEVATED	Ownership · Bias for Action · Learn · Insist	7.0% → 1.8% → 0.3% vs the 0.5% tolerance *(record)*
5	**U7** · 836-row log as the readiness instrument NEW	Dive Deep · Insist · Ownership · Earn Trust	441 of 836 rows Blocker/Critical; 98.0% of them closed *(record, pandas)*
6	**U1** · Node × channel × bucket-transition matrix NEW	Invent and Simplify · Dive Deep · Insist · Earn Trust	every event → exactly one bucket; Blocker + Critical open = 0 at go/no-go
7	**U3** · Merch reserve — the priced no NEW	Backbone · Customer Obsession · Earn Trust · Success & Scale	p* = 36.7% — the price of promising reserve *(modeled)*
8	**U6** · Negative AFS + the correction screen NEW	Dive Deep · Ownership · Customer Obsession · Insist	3 cause classes; negatives clean at T+1; drift 0 *(record design)*
9	**U2** · Profile both books before the design NEW	Dive Deep · Are Right · Learn · Think Big	$2.2M point → $0.74M–$2.2M range; 87% not pooling-dependent *(modeled)*

Three sentences to open with

> "At Sephora's Utah DC I turned two warehouses in one building into one comingle pool — three planning identities over one physical location — through two go-lives and a robotics ramp behind a published 98% gate: +15% processing efficiency, signed by Sephora, and zero customer-facing incidents."
>
> "The number that mattered most was 94 against 98: in week two the node's constraint moved from labor hours to pick accuracy, and a throttle DC Ops owned before the ramp bought a root-caused fix for about 421 labor hours on my model — full volume in week three."
>
> "I ran the program on one 836-row issues log, read Blocker and Critical first — 441 rows, 98% closed — and the rows where the dock, the floor, the power and the footprint were the problem each had a name and a date."

Five numbers never to get wrong

> **+15% processing efficiency · zero customer-facing incidents** — *record — Sephora-signed, DC Ops measured; the dollars are modeled*
>
> **98% gate · week 2 at 94% · ~30% throttle for a week · full volume week 3** — *record*
>
> **7.0% → 1.8% → 0.3% against the 0.5% tolerance published with Finance before mock one** — *record*
>
> **836 rows · 714 closed (85.4%) · Blocker 164 + Critical 277 = 441 (52.8%)** — *record; recomputed from the log with pandas*
>
> **343 tasks / 48,885 task-minutes ≈ 815 h · sync < 99% for 4 h · p95 > 2× for 1 h** — *record*

Never say: "400 devices failed" (say *hundreds of RF devices*) · "20+ systems" (say *about a dozen impacted systems*) · "fifteen tracks" (say *about thirty build tracks*) · any ratio of two modeled dollars · a fifty-times multiplier anywhere (the real figure in the loop is 9.7×, 7 → 68).

Question → Story Router NEW

How to use. Hear the question, find the LP, say the 15-second opener, land the number, then stop. Every question cites the real Amazon bank wording as *AIQB: LP Q#*. "Card" = the angle card under that story (data · conflict/influence/backbone · failure-learning). Story IDs: **S2** Utah DC comingle pool + robotics gate · **S18** WMS migration, two DCs; 0.5% tolerance · **U1** Node × channel × bucket-transition matrix · **U2** Profile both books before the design · **U3** Merch reserve — the priced no · **U4** Where the node's constraint bound · **U5** 343-task runbook, one irreversible instant · **U6** Negative AFS + the correction screen · **U7** 836-row log as the readiness instrument. Basis labels are in the story; *modeled* / *illustrative* are said as such.

LP	AIQB QUESTION (VERBATIM)	PRIMARY STORY → ANGLE	BACKUP	15-SECOND OPENER	ONE NUMBER
Customer Obsession	*Sometimes customers make unreasonable requests. Tell me about a time when you've had to push back or say no to a customer request.* **AIQB: Customer Obsession Q7**	**U3** · conflict card — visibility yes, promisability no	U6 (Q8 — a negative AFS is a promise we cannot keep)	"Merchandising wanted reserve stock promisable — it was in the building. I priced the ask: it pays only above about 37% release, so I said no and offered visibility instead."	**p* = 36.7% *(modeled)***
Ownership	*Describe a time when you didn't think you were going to meet a commitment you promised.* **AIQB: Ownership Q2**	**S18** · failure card — the RF-device test	U5 (Q4 — two go-lives and a runbook over one fast date)	"A device test I scheduled before training showed hundreds of RF devices failing the conversion script — and I had planned that task as low effort. I told leadership straight: training slips a week and a half, the date holds."	**+1.5 weeks; date held *(record)***
Invent and Simplify	*Give me an example of a complex problem you solved with a simple solution.* **AIQB: Invent and Simplify Q1**	**U1** · data card — one rule, one asset	S2 (one pool, three planning identities)	"Three node types, two channels, about a dozen systems — and one rule: every physical event maps to exactly one inventory bucket, tested cell by cell with numbers before and after."	**AFS 557, not 560 or 554 *(illustrative trace)***
Are Right, A Lot	*Tell me about a time when you didn't have enough data to make the right decision.* **AIQB: Are Right, A Lot Q1**	**U2** · failure card — the point became a range	U1 (the in-transit cells the floor taught us to add)	"The case said "pool them," and I did not have the demand profile. I profiled both books by node — overlap, order shape, variability — and turned a $2.2M textbook number into a $0.74M–$2.2M range with the measurement that would settle it."	**$0.74M–$2.2M *(modeled)*; 87% not pooling-dependent**
Learn and Be Curious	*Describe a time when you took on work outside of your comfort area. How did you identify what you needed to learn to be successful?* **AIQB: Learn and Be Curious Q2**	**S18** · Learn answer — month one on the floor	U2 (Q1 — the pooling math, learned in discovery)	"I had never run a WMS migration and had eight months. I wrote the charter in week one so the destination existed before my knowledge did, then spent month one on the floor until I could walk receive to ship unaided."	**month 1 on the floor; 7% → 1.8% → 0.3%**
Hire and Develop the Best	*Tell me about a time when you provided coaching for a team member. What started the coaching?* **AIQB: Hire and Develop the Best Q4**	**S15** bench (Josyula's primary — only if the question demands it)	U6 (four control-owner groups ran the screens without me)	"A QA lead feared compressed test windows — and she was right. I coached the frame and she wrote the definition of done; by cycle two she was defending the gate without me."	**critical defects per release −50% *(record)***
Insist on the Highest Standards	*Describe a time when you refused to compromise your standards around quality/customer service, etc.* **AIQB: Insist on the Highest Standards Q1**	**S2** · conflict card — the 98% gate	S18 (the 0.5% tolerance published before mock one)	"I published the standard before there was any pressure to waive it: a 98% pick-accuracy gate and a throttle dial DC Ops owned. Week two read 94, so the gate fired — bots to about 30% for a week, full volume in week three."	**98 → 94 → ~30% → full volume wk 3 *(record)***
Think Big	*Tell me about time when you were working on an initiative or goal and saw an opportunity to do something much bigger or better than the initial focus.* **AIQB: Think Big Q1**	**U2** · Think Big answer — two pools to one	S2 (the one-omni-facility ask)	"The ask was a number on pooling; the bigger prize was one physical pool with three planning identities — each channel kept its forecasting lens, and the self-transfers went to zero by construction."	**2 pools → 1; ≈260K units/yr self-transfers → 0 *(illustrative volume)***
Bias for Action	*Give me an example of a calculated risk that you have taken where speed was critical.* **AIQB: Bias for Action Q1**	**U4** · data card — the dial fires	S2 (the throttle decision)	"Week two of the robotics ramp read 94 against a published 98. The dial was built in advance and DC Ops owned it, so we throttled to about 30% that same week and root-caused the zone and slotting logic."	**94 vs 98 → ~30% → full volume wk 3 *(record)***
Frugality	*Give me an example of how you have helped save costs or eliminate waste within your role or organization.* **AIQB: Frugality Q1**	**S2** · data card — duplicate handling removed	U4 (Q4 — priced both sides of the throttle)	"Two warehouses in one building were transferring stock to themselves and paying duplicate handling for zero customer value. One comingle pool removed that cost, and DC Ops measured +15% processing efficiency."	**+15% *(record)*; ≈$1.6M/yr *(modeled)***
Earn Trust	*Tell me about a time when you had to communicate a change in direction that you anticipated people would have concerns with.* **AIQB: Earn Trust Q1**	**S2** · conflict card — Digital's concern became the design	U7 (Q6 — the worst number in the room was mine to say)	"Digital worried a virtual Retail DC would blur their forecasting lens, and they were right to. I did not argue them out of it — I made the concern the design: three planning identities over one physical location."	**3 identities, 1 location; 60+ stakeholders**
Dive Deep	*Tell me about a situation that required you to dig deep to get to the root cause.* **AIQB: Dive Deep Q2**	**U6** · data card — a negative has three causes	U7 (the log, three cuts) · U2 (the profile)	"A negative AFS is not one problem. I decomposed it to three cause classes — a duplicate event, a feed that had not caught up, an override — each with an owner, and every AFS-changing act got a screen, a role and an audit row."	**3 cause classes; drift 0 on consecutive days *(record)***
Have Backbone; Disagree and Commit	*Describe a time when you took an unpopular stance in a meeting with peers and your leader.* **AIQB: Have Backbone; Disagree and Commit Q2**	**S2** · conflict card — two go-lives, not one	U5 (Q5 — no UAT compression after the Locus RTL slipped three weeks)	"The prevailing instinct was one go-live, one date. I challenged it: one go-live puts a reserve-rule defect and a floor defect in the same room the same week — so January proved the rules and May moved the floor."	**2 go-lives, 1 defect class each**
Deliver Results	*Give me an example of a time when you were able to deliver an important project under a tight deadline.* **AIQB: Deliver Results Q1**	**U5** · Deliver answer — 61 days, peak untouched	S18 (eight months, ~3% under) · S2 (Q3, +15% signed)	"The window was 61 days, May 1 to July 1, with the Oct–Dec peak freeze behind it — so I wrote the cutover as 343 owned tasks, about 815 hours, each with a predecessor, and the two go-lives landed on their dates."	**343 tasks · ~815 h · 61 days *(record)***
Strive to Be Earth's Best Employer	*Describe a time when you implemented a change at work aimed at improving the work experience of yourself or coworkers.* **AIQB: Strive to Be Earth's Best Employer Q3**	**U4** · Employer answer — the stop condition belongs to the floor	S15 bench (QA lead elevated, not blamed — Josyula's)	"The floor was the one place a bad ramp would land. I wrote the gate and the dial before the robots arrived and DC Ops owned them — so when week two read 94, the stop condition belonged to the people who carry the consequence."	**dial owned by DC Ops before the ramp; ~30% for one week**

LP	AIQB QUESTION (VERBATIM)	PRIMARY STORY → ANGLE	BACKUP	15-SECOND OPENER	ONE NUMBER
Success and Scale Bring Broad Responsibility	*Tell me about a time when you considered everyone who was affected by your work, not just your direct customers or people within your organization.* **AIQB: Success and Scale Bring Broad Responsibility Q5**	**U3** · Success & Scale answer — a broken promise is a defect	U6 (the screens and owners that keep a promise true)	"An oversell looks like a ledger error to a planner and a broken promise to a customer. At an illustrative thirty million orders a year that is thirty thousand customers, so I treated it as a defect with an owner and a screen."	**30,000 customers/yr *(illustrative)* → zero incidents *(record)***

THE ELEVEN NON-LP PROMPTS — SAME GRID NEW

PROMPT	PRIMARY → ANGLE	BACKUP	15-SECOND OPENER	ONE NUMBER
"Tell me about a time you failed."	**S18** failure card (Apple G2)	U6 · U5 failure cards	"The RF-device test failed before training; I had planned it low-effort, I said so the same day, and I now give every single-point dependency a what-if plan."	**+1.5 wk; date held**
"Disagreed with your manager."	**S2** two go-lives (conflict card)	U5 no UAT compression	"The instinct was one go-live; I put the two-defect-class argument in front of leadership and we staged it."	**2 go-lives, 1 class each**
"Influence without authority."	**S2** · 60+ stakeholders	U3 · U6 (owners I did not manage)	"None of the systems reported to me; I owned the model, the gates and the signature chain, and made the concern the design."	**60+ stakeholders**
"Reduced cost."	**S2** · +15%, self-transfers gone	U4 priced the throttle	"One pool instead of two removed duplicate handling; the +15% is signed, the ≈$1.6M a year is my model."	**+15% record; ≈$1.6M/yr modeled**
"Dealt with ambiguity."	**U2** · profile first	S18 charter in week one	"Two books, two warehouses and no agreed model — I profiled SKU overlap, order shape and variability before anyone argued design."	**9.9%–29.3% release**
"Simplified a process."	**U1** · one rule, one asset	S2 · U7 one grammar	"Every event maps to exactly one bucket, and no story entered QA without a cell reference."	**557, not 560 / 554**
"Decision with incomplete data."	**U3** · the break-even	U2 bounded range	"I could not know the release rate, so I priced the decision at the rate where it flips."	**p* = 36.7%**
"Missed a deadline."	**U5** · Locus RTL +3 weeks	S18 training +1.5 wk	"A vendor slipped three weeks; I escalated the week it surfaced, re-slotted openly and refused to compress UAT."	**3 wk slip; UAT intact**
"Mentored someone."	**S15** bench (Josyula's)	U6 control-owner handoff	"I coached the frame, the QA lead owned the gate, and she defended it without me."	**−50% critical defects**
"Tight timeline."	**U5** · 61 days	S18 · eight months	"343 tasks, about 815 hours, every one with an owner and a predecessor."	**61 days**
"Changed your mind with data."	**U2** · $2.2M point → range	U4 constraint moved	"I had carried the textbook pooling number; the overlap and correlation tests said carry a range with a kill number."	**$0.74M–$2.2M**

Spend rule. One question, one story. If an LP is asked twice, move to the named backup, not a story allocated to another interviewer. S15 is Josyula's primary — use it only if the question demands it and keep every fact identical to his packet. Real failure chapters (Apple G1/G2/G3) are the source for every failure/learning angle; none is invented.

Read me first

The interviewer's lens (inference from title + JD — not a biography)

Inference from the title. "Infrastructure" in a fulfillment network means the physical and systems substrate the process runs on — buildings, automation and robotics, the WMS/WCS layer, capacity and launches, cutovers and peak readiness. A Senior Manager there is accountable for changes that touch the floor: go-lives that cannot drop a shipment, automation ramps that must not erode throughput, and migrations where inventory accuracy cannot wobble. He will care about gates, rollback, freeze windows, hypercare exits, and what happened when the plan met the floor.

What that means for the answers. The two Sephora distribution-center programs: S2 (two systemic warehouses in one building consolidated into one comingle pool, with a WMS upgrade and a robotics ramp on the same critical path and zero customer-facing incidents allowed) and S18 (a dual-DC legacy-WMS migration run to a 0.5% reconciliation tolerance published before the first mock, with the RF-device miss owned). Tell them as Make/Deliver process redesigns — one inventory pool instead of two, a cutover discipline instead of a date — with asset utilization (+15% processing efficiency, labor-hours, capital pooled) and reliability (zero incidents, 0.3% against 0.5%) as the results. The vendor teams configured BlueYonder and Locus; DC Ops ran the floor; I owned the model, the staging, the gates and the go/no-go.

Three guessed LP focus areas, with rationale

> **Labeled guess.** Amazon assigns 2–3 Leadership Principles per interviewer and does not disclose them. These three are inferred from the title and the JD; if the first question lands on a different LP, the twist maps under each story carry the pivot.

GUESSED LP	WHY THIS INTERVIEWER WOULD CARRY IT	STORY TO OPEN · BACKUP
Insist on the Highest Standards	Infrastructure owners live by gates that can stop the program: the 98% robotics gate that fired at 94 (S2) and the 0.5% tolerance published with Finance before mock one (S18) are the primary and backup for this LP in the master map.	S2 (open) · S18 (backup)
Bias for Action	When the floor breaks the plan — hundreds of RF devices failing the conversion script in a pre-training device test — he wants to see a decision taken the same day, the cost priced and the date held.	S18 (the device-test miss) · S2 (the throttle to ~30%)
Deliver Results / Ownership (one of the two)	Two go-lives, peak untouched, +15% signed by DC Ops; an eight-month migration on time and ~3% under budget with a $20M pipeline unblocked. Ownership shows in the RF miss carried with my name on the cause.	S2 (the comingle launch) · S18 (8 months, both DCs)

Answer strategy — business first, systems as enablers

- **Open with the process problem and its cost, not the system.** First sentence names the broken process (Plan, Source, Make, Deliver or Return), who it hurt (customer, Finance, the floor) and the baseline number. The platform appears only as the enabler of the redesign, in one clause.
- **Use the JD's four outcome words as the results frame:** reliability (did the promise hold?), responsiveness (how much earlier did we see it?), cost efficiency ($ with its basis label), asset utilization (capital, labor-hours, capacity released).
- **Action = operating-model redesign in gated phases** — Discovery → Plan & Design → Build & Test → Cutover → Hypercare, each spoken as entry bar · what I delivered · exit bar. Say the gate that fired, not the meeting that happened.
- **Every dollar carries its basis word in the same breath** — record · user anchor · modeled · priced. A record dollar is said flat; a modeled dollar is said with its inputs. Never promote a modeled number to record.
- **Program-lead voice.** I owned definitions, rules, gates and the signature chain; engineers, SIs and vendor teams configured and built to the spec I signed. The only platform personally configured in canon is Manhattan DOM.
- **The pitch ends on the primary metric.** Then stop. Silence after the pitch is the interviewer filling their STAR worksheet; their probes are the second half of the answer.
- **For Infrastructure specifically:** speak in gates, invariants and triggers — the published ramp gate and the throttle built in advance; the six cutover invariants (Σ AFS conserved; no SKU sellable in two places; negatives cleared first); rollback triggers as numbers (sync < 99% for 4 h; p95 > 2× for 1 h); hypercare exit as a number (< 2 blockers/day sustained). A gate that cannot stop the program is decoration.
- **Asset utilization is the result frame:** +15% units per labor-hour (signed), one pool instead of two (√2 pooling, modeled and labeled), self-transfers inside one roof eliminated, robotics at full volume by week three, $20M of pipeline unblocked on the date.

Loop-consistency rule. One question, one story; never the same story to two interviewers — interviewers compare notes. Held for other packets (do not spend here): S11/S12 (Tripathy) · S6/S8 (Hoerger) · S1/S3 (Lan) · S16/S15/S10/S14 (Josyula). **v2 overlap:** U1, U3 and U6 re-cut the AFS, merch-reserve and bucket-matrix facts that sit in Lan's S1 — the numbers are identical in both packets; answer from U1/U3/U6 only when the question is about the building, and say the program is the same. S5 (the architecture council) shares the UDC program's dated chain with S2 — Lan's backup pointer, not yours; S2 and S1 share program-level artifacts (issues log, rollback triggers) — if asked, say so.. If pushed for "another example" on an LP, use the named backup in the question bank or the backup bench at the end of this packet, never a story allocated to another interviewer.

How to read the "L6 level evidence" block under each story. Amazon's L6 functional bar (user-supplied rubric): *Ambiguity* — strategy or network undefined; I select the stakeholders, set the goals, deliver independently. *Scope & influence* — team-level scope; influences one to two levels up. *Execution* — tactical and strategic; simplifies or extends; applies best practices; force-multiplies; mitigates long-term risk; makes the short-versus-long-term trade-off explicit. *Impact* — long-term team goals. *Process improvement* — operational-excellence best practices institutionalized. *Complex* — visible risks, roadblocks and constraints mitigated through expertise, judgment and influence to consensus. Overview themes the block is tuned to: designing and modeling the supply chain rather than working in it; developing new processes for others to own; root-cause mechanisms that resolve trending issues at scale; recommendations to leadership that outline competing metrics. The block sits right after Results so the evidence is on the page when the probing starts.

NACF inbound bridge — one whiteboard for nine stories NEW

Every story ends with one sentence that lands on NACF. The sentence rides on the inbound booklet's frames — CAP-A doors, CAP-B UPH, CAP-C cube, CAP-D dwell, CAP-E peak buffer, INV-D transfer break-even — on the booklet's own illustrative FC (120,000 units a day). Draw this chain first, then say which link the story's constraint lives in.

FRAME	LINK	FORMULA → SUBSTITUTION	BASIS	VALUE
A	Doors	`120,000 ÷ 6 ÷ 40 = 500 pallets; ÷ 26 = 19.2 trailers/day; ÷ 10 h = 1.92/h; ÷ 0.5 trailer per door-hour = 3.84 doors; ÷ 0.85 = 4.5`	booklet CAP-A · illustrative FC	**5 doors**
B	UPH labor	`120,000 ÷ 300 = 400 h; × 1.15 = 460 paid h; 0.7 × 300 + 0.3 × 180 = 264 blended; 120,000 ÷ 264 = 454.5 h`	booklet CAP-B · 300 UPH, 60% learning curve illustrative	**+13.6% hours**
C	Cube	`2,000,000 × 0.25 = 500,000 ft³; 1,200,000 × 0.85 = 1,020,000 effective; 500,000 ÷ 1,020,000`	booklet CAP-C · 0.25 ft³/unit illustrative	**49.0% true use**
D	Dwell	`2.0 ÷ (1 − 0.85) = 13.3 h; 2.0 ÷ (1 − 0.95) = 40.0 h; 40.0 ÷ 13.3 = 3.0×`	booklet CAP-D · qualitative queueing approximation	**85% → 95% ≈ 3× dwell**
E	Peak buffer	`156,000 ÷ 264 = 591 h; 591 − 454.5 = 136 h; ÷ 10 = 13.6`	booklet CAP-E · p90 156,000 illustrative	**≈14 flex heads**
D′	INV-D	`$3.00 ÷ $12 = 0.25 — transfer when stockout probability > 25%`	booklet INV-D · $3.00 transfer, $12 margin illustrative	**p* = 25%**

STORY → FRAME → THE QUESTION I WOULD ASK AT NACF

STORY	WHAT THE NODE TAUGHT	THE NACF SENTENCE	FRAME
S2	A published ramp gate and a dial the floor owns (94 vs 98 → ~30%).	Which link binds this week at a new FC — doors at the 85% line, UPH after the learning-curve tax, or cube at 49% effective — and who owns the stop?	A · B · C
S18	Tolerance published before mock one; a freeze sized to the longest lane; a what-if for the single-point dependency.	Publish the receipt-reconciliation tolerance before the first mock; hold 5 planned doors against 3.84 raw — about 1.2 doors of slack — so a day-one surprise does not move the date.	A · D
U1	Every event lands in exactly one bucket; zero or two is a defect.	"Stranded" inventory is an event that landed in zero states. Build the receive → stow → sellable event matrix before an FC ramps.	booklet "stranded"
U2	Profile overlap, order shape and correlation before pooling is claimed.	Do two FCs carry the same ASINs and see the same demand? Pooling pays only at low correlation; the physical move is INV-D — transfer when p > 25%.	INV-D
U3	Merch reserve is in the building and not promisable; p* = cost ÷ (gain + cost).	Promise pickable, not received. Same break-even shape as INV-D (3 ÷ 12); 10,000 reserved units at 0.25 ft³ hold 2,500 ft³ of the 1,020,000 effective.	C · D′
U4	The constraint moved from labor hours to accuracy; the throttle cost ≈421 h.	421 h is about 10.5 people for a week against CAP-B's 13.6% learning tax and CAP-E's ~14 flex heads — name the binding resource first.	B · E
U5	One irreversible instant; stop conditions written as numbers before the first task.	The first live inbound appointment is the irreversible instant; the 85% door ceiling is the slack that absorbs a re-pointed or late trailer.	A · D
U6	A negative AFS decomposes to duplicate event, feed latency, override.	Committed units above what the building can back: a double receive scan, dock-to-stock lag, a manual adjustment — zero-tolerance reconciliation of dock-received vs system-available.	D
U7	The issues log read severity-first, with the dock, power and footprint rows named.	Launch register with the dock row at the top: appointments, placards, pallet-build positions; a SKU with no footprint defaults a slot, which is wasted cube at the 85% line.	A · C

All booklet inputs are the booklet's own illustrative FC; nothing here is a Sephora figure. The people-week conversion assumes a 40-hour week (421 ÷ 40 = 10.5).

The stories — business-first, canon numbers

Nine primaries on the Sephora distribution-center work: S2 and S18 (elevated) and seven new cuts of the same node facts, U1–U7. Each: 60-second pitch → Situation/Task → Action in gated phases → Results → L6 evidence → five facets and probing → the four-table math → Twist map → behavioral pack, angle cards, trap drills, 20-second version and NACF bridge.

S2 — Sephora Utah DC — two systemic warehouses in one building → one comingle pool, coupled with a WMS upgrade and a robotics ramp behind a published gate (+15% processing efficiency, zero customer-facing incidents) ELEVATED

LPs this story can serve here: Insist on the Highest Standards (primary — the 98% gate that fired at 94) · Deliver Results (two go-lives, peak untouched) · Have Backbone (the throttle) · Strive to be Earth's Best Employer (the floor protected during the ramp) · Bias for Action (the throttle decision the week the gate failed)
Process family: Make / Deliver — DC operating model (one inventory pool, three planning identities), automation ramp governance, staged go-lives, cutover runbook, hypercare exit

Honesty label. I owned discovery through FSD for the location and inventory model, the staging and the gates; BlueYonder, Locus and the platform teams built and configured; DC Ops ran the floor and measured the +15% post-stabilization. The +15% is Sephora's signed number; every dollar is my model on an illustrative 100K-units/week DC. Program-level artifacts (dated gate chain, 836-row issues log, rollback triggers) are shared with S1/S5 — one umbrella program.

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH

Insist on the Highest Standards. I published the robotics gate — 98% pick-accurate — before the robots arrived; when week two read 94 it fired and the bots went to ~30% for a week.

Deliver Results. Two go-lives on their dates, each carrying one defect class, peak untouched, zero customer-facing incidents and +15% processing efficiency signed by Sephora.

Have Backbone; Disagree and Commit. I challenged the single-go-live instinct and held the comingle-reserve improvements out of the release to protect zero incidents — priced as a later enhancement.

Strive to be Earth's Best Employer. The throttle and the DC-Ops-owned dial protected the floor's throughput during the ramp; the interim reporting burden was named as the price. No headcount or attrition number is claimed.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. Sephora's Utah DC ran as two systemic warehouses in one building — Dotcom 801 and Retail 901 — transferring stock to itself and paying duplicate handling for zero customer value. The ask was one omni comingle facility, with a BlueYonder WMS upgrade and Locus robotics on the same critical path, an October–December peak freeze, about a dozen impacted systems, 60+ stakeholders, and zero customer-facing incidents allowed. **Task.** I owned discovery through the signed design for the location and inventory model, the staging and the acceptance gates. **Action.** I redesigned the operating model as one physical pool with three planning identities, so each channel kept its forecasting lens without a second truth; split the program into two go-lives so each carried one defect class — January proved reserve rules against live demand with the floor untouched, May moved warehouse execution; published the robotics gate at 98% pick-accurate throughput with the throttle dial built in advance and owned by DC Ops; ran three mock cutovers against the 0.5% tolerance and a 343-task runbook whose one irreversible instant was zero-then-publish, so nothing was sellable in two places. When week two of the robotics ramp hit 94 against 98, the gate fired: bots throttled to about 30% of volume for a week, zone and slotting logic root-caused, full volume week three. **Result.** Primary metric: DC processing efficiency — baseline index 100 → 115, +15%, Sephora-signed, measured by DC Ops post-stabilization; zero customer-facing incidents through both go-lives; rollback armed twice, never fired. About $1.6M a year modeled — labor at +15%, pooling carry, fewer split shipments, self-transfer handling removed — and about $2.2M of one-time safety stock released by pooling, also modeled; the +15% and the zero are the record.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — The Utah DC ran as two systemic warehouses — Dotcom 801 (selling location 800) and Retail 901 — transferring stock to itself and paying duplicate handling for zero customer value. The ask: one omni/comingle facility, with a BlueYonder WMS 8.2 → 2023.1 upgrade and Locus robotics on the same critical path, about a dozen impacted systems, an Oct–Dec peak freeze, zero customer-facing incidents allowed.

The challenges sat on the critical path itself: the WMS upgrade and the robotics ramp shared it, the peak freeze bounded it, and the interim would run two live truths. The register's top three risks — two live truths during the interim, a robotics ramp with no stop condition, and a peak collision — each had a trigger, a mitigation and an owner before sign-off.

T — Discovery through FSD for the location and inventory model, the staging and the acceptance gates; 60+ stakeholders (~80 names across ~15 functions) on the steering path; none of the systems reported to me.

Baselines on the table: processing efficiency index 100 (units per labor-hour) · customer-facing incidents allowed: 0 · robotics gate 98% published in advance from the pre-ramp baseline and the incident budget · self-transfers and duplicate handling — the standing cost one pool exists to remove.

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery (3/29 → 4/30)** — profiled 801/901 (SKU overlap, order profiles); sponsor objectives and success criteria — one omni facility, self-transfers eliminated, zero customer-facing incidents, peak untouched; systems-impacted table. *Exit bar:* every impacted system named to an owner with a written LOE (landed 7/2); criteria signed by steering.
- **Plan & Design (5/15 → 8/14)** — council pack (three decisions + an out-of-scope fence); the 900/901 location/inventory model with three planning identities over one physical location; staged two-go-live timeline; RAID log; FSD 8/14. *Exit bar:* council sign-off 7/31; FSD 8/14; peak-freeze boundary decided; LOE-backed plan across ~30 build tracks.
- **Build & Test (Aug → Jan/Apr)** — node × channel × bucket-transition matrix as the regression asset; dated E2E days — Inbound 11/22, Dotcom 12/20, Retail 1/30 — every function in one room; Locus gate definition (98%) with the throttle spec; three mock cutovers against the 0.5% tolerance (the S18 discipline reused); the Locus RTL slipped three weeks — escalated the week it surfaced, re-slotted openly, UAT not compressed to absorb it. *Exit bar:* E2E green on three dates; Blocker + Critical open = 0 at each go/no-go; mock 3 inside tolerance.
- **Cutover & Go-Live (January; May 1 → Jul 1)** — runbook of 343 tasks / ~815 hours, each with owner, duration and predecessor; six-step May choreography — clear negatives, transfer AFS to Uncommitted, scan-and-reserve, zero-then-publish; rollback triggers per interface (sync < 99% for 4 h; order-flow p95 > 2× budget for 1 h). *Exit bar:* six invariants held (Σ AFS conserved; no SKU sellable on 800 and 900 at once; negatives cleared first); rollback never fired.
- **Hypercare / Close (Jun → Jul)** — monthly arc of new issue rows 271 → 65 → 21 → 14 → 4 (June → October); Locus weekly gate read — week 2 at 94 vs 98 → throttle to ~30% → RCA (zone/slotting logic) → full volume week 3; hypercare exit memo; template handed to the next DC. *Exit bar:* < 2 blockers/day sustained → exit week 3 of 4; +15% measured post-stabilization by DC Ops.

Influence and ownership. Mine: the location/inventory model, the staging, the gates, the council pack, the runbook and the go/no-go recommendation. BlueYonder, Locus and the platform teams built and configured; DC Ops ran the floor, owned the robotics gate and the dial before the ramp — so when it fired, the rule fired; I did not improvise. Digital worried a virtual Retail DC would blur their forecasting lens — the three-identity design made the concern the design rather than an argument. The comingle-reserve improvements were held out of the release to protect zero incidents, priced as a later enhancement at steering.

> **Designed the process; others own it now.** I designed the location/inventory model, the gates and the throttle dial; DC Ops owned the dial before the ramp and runs the floor on it, and the hypercare template went to the next program. **Trade-off put to leadership.** The recommendation to leadership outlined the competing metrics — +15% processing efficiency and the robotics ramp vs zero customer-facing incidents and peak untouched — and made the gate (98%) and the throttle (~30%) the published answer before the robots arrived.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY (CANON NUMBERS ONLY)

- **$** — ≈$1.6M/yr *modeled* (labor at +15% ≈$0.88M · pooling carry ≈$0.22M · fewer split shipments ≈$0.45M · self-transfer handling ≈$0.10M) + ≈$2.2M one-time safety-stock release *modeled* via √2 pooling; the +15% is Sephora's signed number; every dollar is my model on an illustrative 100K-units/week DC (range $1.1–2.4M/yr).
- **#** — cutover runbook 343 tasks / 48,885 task-minutes ≈ 815 hrs; issues log 836 rows / 85.4% closed; monthly new-row arc 271 → 65 → 21 → 14 → 4 (record, from the log).
- **%** — processing efficiency +15% (record, Sephora-signed); robotics gate 98%, week 2 at 94, bots throttled to ~30% of volume for a week, full volume week 3 (record).
- **Time** — council 5/15 → sign-off 7/31 → FSD 8/14; E2E 11/22 · 12/20 · 1/30; January and May go-lives; hypercare exited week 3 of 4 (record).
- **Customer** — zero customer-facing incidents through both go-lives (record) — the constraint every other number moved inside.
- **Quality** — six cutover invariants held; rollback armed for both go-lives, never fired; peak untouched (record).

L6 LEVEL EVIDENCE — what the interviewer pattern-matches against the Amazon L6 functional rubric; every line is this story's canon, no new numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	Two systemic warehouses in one building and no agreed operating model. I owned the location/inventory model (three planning identities over one physical location), the staging and the gates, and set the success criteria with the sponsor — one omni facility, self-transfers eliminated, zero customer-facing incidents, peak untouched.
Scope & influence	BlueYonder, Locus and the platform teams built and configured; DC Ops ran the floor and owned the robotics gate and the dial; the go/no-go recommendation was mine to leadership — influence across about a dozen impacted systems and 60+ stakeholders I did not manage.
Execution trade-off + mechanism others now own	Robotics throughput vs floor stability: the 98% gate fired at 94 in week 2, bots throttled to ~30% for a week, full volume week 3. Mechanism others own now: the dial, owned by DC Ops before the ramp, and the hypercare template handed to the next program.
Impact (long-term)	Processing efficiency +15% (Sephora-signed); zero customer-facing incidents through both go-lives; ≈$1.6M/yr modeled plus ≈$2.2M one-time modeled; peak untouched.
Process improvement (standard work institutionalized)	The node × channel × bucket-transition matrix as the regression asset; a runbook of 343 tasks / ~815 hours with owner, duration and predecessor; six cutover invariants; a monthly new-row arc 271 → 4.
Complexity & consensus	Staged two go-lives (January planning / May execution) so each carried one defect class; a peak-freeze boundary; dated E2E days (11/22 · 12/20 · 1/30) with every function in one room.
Root cause at scale	The week-2 robotics miss was root-caused to zone/slotting logic and fixed before full volume — the rule fired, the cause was removed, the ramp was not pushed through.

PROBING — FIVE FACETS, THEN THE HARDEST FOLLOW-UPS NEW

THE FIVE FACETS — WHERE EACH ONE LIVES IN THIS STORY

1 · Data analysis. Grain: node × week × bot share; SKU × pool. Data: both books profiled in discovery (U2), labor hours, picks attempted/accurate, the 836-row issues log, the 343-task runbook. Cuts: accuracy by week; new rows by month (271 → 4). Revealed: the week-2 miss was zone/slotting logic, and the case rested on recurring rows more than on pooling.

2 · Solution design. Options: (A) keep two warehouses and reconcile; (B) one pool, one blended planning lens; (C) one physical pool, three planning identities (chosen); and a staging choice — one go-live vs two (chosen: two, each carrying one defect class). Why: C keeps Digital's forecasting lens without a second truth; two go-lives keep diagnosis univariate.

3 · Math & data logic. +15% → hours 240,000 / 1.15 = 208,700 (−13.0%); pooling 1 − 1/√2 = 29.3% on $7.5M → $2.2M (bounded in U2); gate T = accurate ÷ attempted ≥ 98%; throttle 100% → 30% (bounded in U4); AFS conserved (U5).

4 · Implementation. Five gated phases (3/29 → 4/30 → 5/15 → 7/31 → 8/14 → E2E 11/22 · 12/20 · 1/30 → January → May 1 → Jul 1 → hypercare); owners: me (model, staging, gates, go/no-go), BlueYonder/Locus/platform (build), DC Ops (floor, gate, dial). Controls: Blocker + Critical = 0, mock 3 ≤ 0.5%, rollback triggers.

5 · Probe questions. The six answered above in the Probing block; the zoom-ins that stand alone are U1 (matrix), U2 (profile), U3 (reserve), U4 (capacity), U5 (runbook), U6 (negatives).

FACET 5 — PROBE QUESTIONS (CHALLENGE Q&A TUNED TO THIS INTERVIEWER)

Infra — Why 98%, and what did you actually do at 94?

98% was set from the pre-ramp baseline and the incident budget before the event, and DC Ops owned it. At 94 in week two I throttled the bots to about 30% of volume for a week, root-caused the zone and slotting logic, and ramped again — full volume by week three. A gate that cannot stop the program is decoration; mine did.

Infra — Why two go-lives instead of one big one?

So we never hunted two defect classes in the same week. January proved reserve rules against live demand while the floor was untouched; May left warehouse execution as the only remaining class. One go-live would have put a reserve defect and a floor defect in the same room.

Infra — What made you say go in May?

Counted rows, not the room: Blocker + Critical at zero, mock 3 inside the 0.5% tolerance, the 343-task runbook rehearsed, rollback armed per interface. I would have said no-go on one open Blocker; I never had to.

Infra — What were the rollback triggers and did any fire?

Sync below 99% for four consecutive hours, or order-flow p95 above twice budget for one hour — rollback per interface behind them. Armed for both go-lives; never fired. The one irreversible instant was step 4, zero-then-publish, so no SKU was ever sellable in two places.

Infra — The labor number is the biggest piece of your $1.6M. How firm?

The fifteen percent is measured and signed; the 120 FTE and the $28 loaded rate are my assumptions. Pull the DC's direct hours for the two quarters before and after and multiply by payroll — that turns the model into a record in an afternoon. If the split-shipment row didn't move, the total is about $1.1M.

> **Infra — What would you do differently?**
> Staff the interim reporting workstream on day one, not month three — for four months every report had to declare which system of record it read. And the Locus slip: escalated the week it surfaced, but I would have put the RTL on the register as a risk, not a task, from the start.

THE MATH — FOUR-TABLE DERIVATION (FORMULA → SUBSTITUTION → RESULT) NEW

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Two warehouses in one building	`planning pools = 2 (801 retail + 800 dotcom)`	two planning identities over one roof (record)	2 pools
2	Baseline efficiency	`index = 100 units per labor-hour`	pre-UDC baseline (record)	100
3	Direct labor to run it	`120 FTE × 2,000 h/yr = 240,000 h/yr`	modeled staffing on an illustrative 100K-units/week DC	240,000 h/yr
4	Self-transfers inside one roof	`≈260,000 units/yr moved on paper between 801 and 800`	modeled	260K units/yr of non-work
5	Duplicated safety stock	`$50M × 25% = $12.5M SS; $12.5M × 60% = $7.5M`	avg inventory (illustrative) × SS share × share held in SKUs both pools carry	$7.5M duplicated poolable SS
6	Split shipments	`4,500,000 orders × 1 pt = 45,000 extra splits/yr`	~4.5M dotcom orders/yr; split rate 1 pt above the comingled state (modeled)	45,000 splits/yr

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	One pool, three planning identities	`900/901 model → self-transfers = 0 by construction`	three planning identities over one physical location (record design)	the move is a posting, not a truck
2	Robotics gate (published first)	`T = pick-accurate completed / attempted ≥ 98%`	gate published before the ramp (record)	the dial was built in advance
3	Gate evaluated, week 2	`T = 94%; 94 < 98 → gate failed by 4 pts`	record	throttle fires
4	Throttle	`bot share 100% → 30%; manual covers (1 − 0.30) × 100,000 = 70,000 units/wk`	volume illustrative	RCA, then ramp again — full volume week 3 (record)
5	Efficiency after	`index 100 × 1.15 = 115`	+15% (record, Sephora signed, post-stabilization)	115
6	Hours for the same volume	`240,000 / 1.15 = 208,696 ≈ 208,700 h/yr`	Table 1 row 3 and the +15%	≈208,700 h/yr
7	Hours saved	`240,000 − 208,700 = 31,300; 31,300 / 240,000 = 13.0%`	arithmetic on the two rows above	31,300 h/yr = 13.0%
8	Pooling (2 equal pools → 1)	`factor = 1 − 1/√2 = 1 − 0.707 = 0.293; $7.5M × 0.293 = $2.2M`	√2 pooling (toolkit label; ceiling — bounded in U2)	≈$2.2M one-time
9	Zero-incident fence	`two staged go-lives — one defect class live at a time`	customer-facing incidents allowed: 0 (record constraint)	0 incidents through both

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Processing efficiency (units/labor-hour)	index 100	115	record (Sephora signed)
2	Direct labor hours, same volume	240,000 h/yr	≈208,700 h/yr	modeled on the record +15%
3	Self-transfers	≈260K units/yr	0	record design
4	Poolable safety stock	$7.5M	$5.3M ($7.5M − $2.2M)	modeled (√2 ceiling)
5	Split-shipment rate	baseline on ~4.5M orders	−1 pt	modeled
6	Customer-facing incidents	0 allowed	0 through both go-lives	record

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Labor at +15%	`31,300 h × $28/h = $876,400`	hours from Table 2 row 7; $28 loaded (modeled)	≈$0.88M/yr

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
2	Pooling release	`$7.5M × 0.293 = $2.2M`	Table 2 row 8 (one-time working capital)	≈$2.2M one-time
3	Carry on the release	`$2.2M × 10% = $220,000`	cost of capital (benchmark 8–12%)	≈$0.22M/yr
4	Split shipments	`45,000 × $10 = $450,000`	splits from Table 1 row 6; $10 per split (modeled)	≈$0.45M/yr
5	Self-transfer handling	`260,000 × $0.80 = $208,000; × 50% = $104,000`	50% — the other half already sits in the labor row (modeled)	≈$0.10M/yr
6	Total recurring	`0.88 + 0.22 + 0.45 + 0.10 = $1.65M`	rows 1, 3, 4, 5	≈$1.6M/yr
7	One-time working capital	`= row 2, stated separately`	safety-stock release	≈$2.2M

SPOKEN STATEMENT NEW

> “Conservatively, about one point six million a year: roughly nine hundred thousand of labor, because the same volume takes thirteen percent fewer hours at plus fifteen percent efficiency; about two hundred thousand a year of carry on the two point two million of safety stock one pool releases versus two; about four hundred fifty thousand from fewer split shipments; and about a hundred thousand from the DC no longer shipping to itself. The plus fifteen percent and the zero incidents are measured and signed by Sephora; every dollar figure is my model on an illustrative hundred-thousand-units-a-week DC, and I will tell you which input each one rests on.”

IF CHALLENGED NEW

“The labor number is the biggest — how firm?”

The fifteen percent is measured; the headcount and the $28 loaded rate are my assumptions. Pull the DC’s actual direct hours for the two quarters before and after and multiply by payroll — that turns the model into a record in one afternoon.

“Pooling sounds like a textbook claim.”

It is, and I labeled it. √2 pooling assumes two roughly equal independent pools on the same SKUs. Measure SKU-level on-hand on the last day of 801 versus the first stable month of 901; the release is whatever the difference actually is. U2 bounds it at about $0.74M–$2.2M.

“Split shipments — evidence?”

The softest row. Parcels per dotcom order from the ship system before and after May, times the carrier’s per-parcel cost. If the point didn’t move, I drop the row and the total is about $1.1M.

Where this lands at Amazon. An FC launch/retrofit with automation on the critical path: publish the ramp gate and the throttle before the robots arrive, stage go-lives so each carries one defect class, hold peak sacred, and write the rollback as a number. Zero-then-publish is the same discipline as never letting one unit be promisable from two nodes at once. Asset utilization (+15% units per labor-hour; one pool), reliability (zero incidents, rollback never fired).

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE WITH S2

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Tell me about a time you held a high standard when it was costly.	Insist on the Highest Standards	The 98% gate fired at 94; a week of robot volume traded for a root-caused ramp; full volume week three.	Do not say "the robots failed" — the gate worked as designed.
Tell me about a time you had to slow something down.	Have Backbone / Bias for Action	The throttle to ~30% the week the gate failed — a decision the same week, owned by DC Ops' own rule.	Do not frame it as caution; it was a pre-built dial firing.
Tell me about launching something with zero room for error.	Deliver Results / Customer Obsession	Zero customer-facing incidents through both go-lives as the constraint; two go-lives so each carried one defect class; the six invariants.	Skip the Kafka/ESB topology unless asked.
How did you protect the floor / the people during the change?	Earth's Best Employer	The throttle protected the floor's throughput; DC Ops owned the gate and the dial; the interim's reporting burden named as the price.	Do not invent a headcount or an attrition figure; none exists in canon.
How do you plan a cutover?	Functional — launch readiness	Runbook with owner/duration/predecessor per task; one irreversible instant identified; rollback triggers as numbers; three mocks against a tolerance; hypercare exit as a number.	Never "400 devices failed" (that is S18's RF miss — say hundreds of RF devices).
What's the ROI of the consolidation?	Frugality	+15% signed; ≈$1.6M/yr modeled with the four rows and their inputs; ≈$2.2M one-time pooling, labeled textbook.	Never present the $1.6M as a signed number.

BEHAVIORAL PACK — FOUR SEPARATE 90-SECOND STAR ANSWERS, EACH FROM A DIFFERENT MOMENT OF THE STORY NEW

INSIST ON THE HIGHEST STANDARDS · AIQB Q4 **Q1. "Tell me about a time when you had to make a decision between standards and delivery."**

I published the standard before there was any pressure to waive it. The robots were arriving at the Utah DC, and I wrote the gate — 98% pick-accurate completed over attempted — into the council pack, with a throttle dial and the weekly read, and DC Ops owned the gate and the dial before the ramp. A gate published before the pressure exists is most of the holding. Week two read 94. The floor owner's own rule fired and I throttled the bots to about 30% of volume for a week — a week of robot volume traded for a root-caused ramp. The zone and slotting logic was the cause; it was fixed, and week three ran at full volume. Processing efficiency ended at +15%, signed by Sephora and measured by DC Ops after stabilization. A gate that cannot stop the program is decoration; this one did.

Number to land: 98 published · 94 read · ~30% throttle · full volume week 3 · **Pivot to NACF:** At NACF I would publish the ramp gate for a new FC — the door ceiling, the UPH floor — before the first trailer, with the dial owned by the building. · **Do NOT say:** that the robots failed; that I fixed the slotting logic.

DELIVER RESULTS · AIQB Q3 **Q2. "Tell me about a time when you not only met a goal but considerably exceeded expectations."**

The constraint was zero customer-facing incidents, so I designed the program to carry one defect class at a time. About a dozen impacted systems — with a BlueYonder upgrade and Locus robotics on the same critical path and an October-to-December peak freeze. I split the work into two go-lives: January was the planning go-live — purchasing and inbound, with the reserve rules live against demand — and the floor untouched; May moved warehouse execution. Each go-live was a counted decision: Blocker plus Critical at zero, mock three inside the 0.5% tolerance, a 343-task runbook rehearsed, rollback armed. Both landed on their dates with zero customer-facing incidents, peak untouched, hypercare exited in week three of four, and +15% processing efficiency signed by Sephora. The modeled value is about $1.6 million a year; the +15% and the zero are the record.

Number to land: 2 go-lives · zero incidents · +15% signed · **Pivot to NACF:** At NACF a new FC launch has the same shape: stage it so each step carries one risk class, and decide each step on counted rows. · **Do NOT say:** that the $1.6M is signed; that I ran the floor.

EARN TRUST · AIQB Q1 **Q3. "Tell me about a time when you had to communicate a change in direction that you anticipated people would have concerns with."**

Digital worried that a virtual Retail DC would blur their forecasting lens, and they were right to worry. I did not argue them out of it; I made the concern the design: one physical location with three planning identities, so each channel keeps its lens without a second truth. Across sixty-plus stakeholders I owned none of the systems, so I wrote the success criteria with the sponsor — one omni facility, self-transfers eliminated, zero customer-facing incidents, peak untouched — and steering, meaning DC Ops, IT and Supply Chain Strategy, signed them. DC Ops owned the robotics gate and the dial before the ramp, so when it fired the floor's own rule fired. The build tracks were slotted by business criticality times effort under one issues log. Trust came from putting the concern into the design and the stop condition into the hands of the people who carry the consequence.

Number to land: 60+ stakeholders · 3 planning identities · gate and dial owned by DC Ops · **Pivot to NACF:** At NACF, placement and inbound changes cross many orgs I would not own; I would convert objections into design rows the same way. · **Do NOT say:** that Digital agreed with everything; I know their concern, not their private view.

HAVE BACKBONE; DISAGREE AND COMMIT · AIQB Q2 **Q4. "Describe a time when you took an unpopular stance in a meeting with peers and your leader."**

The prevailing instinct was one go-live: one cutover, one date, done. I challenged it. One go-live would have put a reserve-rule defect and a floor-execution defect in the same room the same week, and with sixty-plus stakeholders and zero tolerance for customer-facing incidents that is a diagnosis problem, not a schedule problem. So I proposed two go-lives so we never hunted two defect classes in one week — January for the reserve rules against live demand, May for execution — and I also held the comingle-reserve improvements out of the release, priced as a later enhancement at steering, to protect the zero. Both landed on their dates. The cost was a second cutover and the discipline of saying no to a good idea at the wrong time; the benefit was single-cause diagnosis.

Number to land: 2 go-lives, 1 defect class each; improvements held out · **Pivot to NACF:** At NACF I would stage a launch the same way and hold good ideas for the next release. · **Do NOT say:** that two go-lives were free; the second cutover has a price.

SAME STORY, THREE ANGLES — DATA · CONFLICT/INFLUENCE/BACKBONE · FAILURE-LEARNING NEW

DATA ANGLE · DIVE DEEP

"Plus fifteen percent means 31,300 fewer hours for the same volume — 13.0% — and about 87% of the modeled benefit does not depend on pooling."

Headline metric: 240,000 → 208,700 h; ≈$0.88M labor

Index 100 → 115 is the record; hours, dollars and the pooling carry are my model on S2's illustrative DC. U2 bounds pooling at $0.74M–$2.2M; U4 prices the throttle at ≈$11.8K vs ≈$50.4K.

CONFLICT / INFLUENCE ANGLE · HAVE BACKBONE; DISAGREE AND COMMIT

"Everyone's instinct was one go-live; I argued for two."

Headline metric: 2 go-lives · 1 defect class each

One go-live would have mixed a reserve defect and a floor defect in the same week; two cost a second cutover. Held the comingle-reserve improvements out of the release; priced at steering. Digital's lens was kept by the three-identity design.

FAILURE / LEARNING ANGLE · OWNERSHIP

"For four months every report had to declare which system of record it read — I staffed that in month three, not day one."

Headline metric: interim reporting staffed month 3 of ~4 months of cost

The record's own do-differently: the interim cost was predictable. Second: the Locus RTL slipped three weeks — escalated the week it surfaced, but it should have been on the register as a risk, not a task.

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS, WITH NUMERIC ANSWERS NEW

How do you know the +15% came from the consolidation and not from the robots or the WMS upgrade?

I don't split it, and Sephora's number doesn't either: +15% is whole-program processing efficiency (units per labor-hour), measured by DC Ops post-stabilization. The consolidation, the WMS upgrade and the robotics were on one critical path by design. Attribution among them would need a before/after on lanes that did not get robots.

Say: *"The +15% is the program's, signed and measured by DC Ops; I would not attribute it to one lever, and the number that would let me is a lane-level before/after."*

What was the counterfactual?

Two warehouses transferring stock to themselves (≈260,000 units a year on paper) and two safety-stock pools — the cost of not consolidating. The counterfactual dollars are modeled; the record is the efficiency and the zero incidents.

Say: *"The counterfactual is modeled; what I can prove is +15% measured by DC Ops and zero customer-facing incidents."*

What did you give up?

The comingle-reserve improvements (priced as a later enhancement), a week of robot volume (the throttle), and for four months a clean reporting picture (the interim). Each was a deliberate trade for zero incidents.

Say: *"Three things, on purpose: the reserve improvements, a week of robot volume, and four months of cleaner reporting — in exchange for zero customer-facing incidents."*

20-SECOND VERSION + NACF BRIDGE NEW

20-second version. At Sephora's Utah DC I merged two systemic warehouses into one comingle pool — three planning identities over one location — through two go-lives and a robotics ramp behind a published 98% gate that fired at 94: +15% processing efficiency signed by Sephora, zero customer-facing incidents, rollback armed twice and never fired.

NACF bridge. NACF capacity chain: one node, one published ramp gate and an owned dial. A new FC's inbound ramp is CAP-A doors held at an 85% ceiling, CAP-B UPH with the learning-curve tax (+13.6% hours), CAP-C cube read at 49% effective — and the same rule that the people who own the building own the stop condition.

S18 — Sephora — legacy WMS → JDA WMS dual-DC migration: a 0.5% reconciliation tolerance published before mock one, three mocks read by cause class (7% → 1.8% → 0.3%), and the RF-device miss owned ELEVATED

LPs this story can serve here: Insist on the Highest Standards (backup — the published tolerance) · Bias for Action (the date held while training moved) · Deliver Results (backup — 8 months, both DCs, gate cleared) · Learn and Be Curious (first WMS migration; learned the floor in month one) · Ownership (the RF miss with my name on the cause)
Process family: Make / Deliver — warehouse execution system cutover across two DCs; inventory-accuracy governance; freeze, failback and hypercare discipline

Honesty label. Full lifecycle owner, accountable to sponsor and Finance; I had never run a WMS migration and learned the floor in month one. Month markers are illustrative unless stated; the RF miss is mine — I scored the task by effort when impact was what mattered. Loop-packet conflict (§1.3): that document says ~$800K budget and ~$2.5M/week; this packet's record is ~$1.8M, ~3% under, and ~$2.5M/month as my division of the $20M (modeled) — say these.

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH

Ownership. The RF miss is mine — I scored the task by effort when impact was what mattered — and I told leadership straight, with my name on the cause.

Bias for Action. When the device test showed the conversion script failing on refreshed RF hardware, I moved training by a week and a half and held the go-live date — and put device readiness into training's entrance criteria.

Learn and Be Curious. I had never run a WMS migration; I wrote the charter in week one and walked receive-to-ship on the floor in month one until I could do it unaided.

Insist on the Highest Standards. I published the 0.5% reconciliation tolerance with Finance before mock one; mock one at 7% was the price and mock three at 0.3% was worth it.

SOURCE CONFLICT — the RF-device miss (read before you say it). Master canon (S18): ~100 of ~400 RF devices failed the conversion script *at cutover*; a rehearsed paper-pick fallback fired; ≈$45K fallback against ≈$875K of slip. Apple v11, chapter G2 (from your 2022 failure notes): the upgrade script failed on refreshed RF hardware in a device test scheduled *days before training*; manual conversion could not finish under COVID night shifts; training slipped 1.5 weeks; the notes record ~400 devices in one telling and ~100 in another — "say hundreds in the room." Precedence applied (source docs, then Apple v11, then master): every line I added to S18 says "hundreds", "the pre-training device test", "training +1.5 weeks, the date held", and none says the paper-pick $45K or the ≈19× ratio. The S18 body above has been brought to the Apple G2 wording for the RF-device miss; the master's paper-pick and ~19× lines are not carried forward. Common ground in every version: the miss was mine, scored by effort not impact, training slipped 1.5 weeks, the date held, ~3% under budget. Pick the telling you lived and use it identically in all five interviews. Listed as a source conflict on the Verify-before-you-say-it page.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. Two Sephora DCs ran on a legacy WMS with no documentation, an eight-month hard deadline, a ~$1.8M budget, and a $20M ROI pipeline of four programs gated behind go-live — about $2.5M a month of slip on average (my division of the $20M, not banked). Inventory accuracy across two DCs could not wobble at cutover, and I had never run a WMS migration. **Task.** Own the full lifecycle — charter, design sign-off, the ERP ↔ WMS ↔ 3PL ↔ carrier interface inventory, UAT, cutover, hypercare — accountable to the sponsor and Finance. **Action.** I wrote the success criteria in week one — on the date, inside a published reconciliation tolerance, zero accuracy incidents, a numeric hypercare exit — and learned the floor in month one until I could walk receive-to-ship unaided. I built the interface inventory from message logs with an owner and a test cell per contract, set the mapping-table standard as data not code, and published the 0.5% tolerance with Finance before mock one so the number belonged to us before the test. Three mocks were read by cause class, not headline: 7% (units of measure, location names, status vocabularies) → 1.8% (in-transit timing) → 0.3%. Cutover ran a 72-hour in-transit freeze with the legacy system read-only for 30 days. When a device test before training showed hundreds of RF devices failing the conversion script, inventory was inside tolerance and the failure was device conversion, not data — so I held the date, let the training criterion slip 1.5 weeks, and told leadership the same day. **Result.** Primary metric: inventory reconciliation variance at cutover — 7% → 1.8% → 0.3% against the 0.5% tolerance. On time, about 3% under the ~$1.8M budget (~$54K), the $20M pipeline unblocked the next month — slip avoided, not banked. Hypercare exited week three at under two blockers a day. The RF miss is mine.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — Two DCs on a legacy WMS; zero inherited documentation; a hard eight-month deadline with a $20M ROI pipeline of four programs gated behind go-live (~$2.5M/month of slip — my division, modeled); budget ~$1.8M; I had never run a WMS migration. Inventory accuracy across two DCs could not wobble at cutover.

The register at design sign-off: undocumented interface surprises, conversion mismatch above tolerance, and 3PL/carrier freeze non-compliance — each with a trigger, a data-first mitigation and an owner. The one I missed: RF device conversion sat on the log as a task, not a risk.

T — Own the full lifecycle — discovery charter, design sign-off, the ERP ↔ WMS ↔ 3PL ↔ carrier interface inventory, UAT, cutover, hypercare — accountable to the sponsor and Finance. Team: 14 core + 6 DC Ops.

Baselines on the table: conversion mismatch — gated at the 0.5% tolerance signed with Finance before mock 1 (mock 1 opened at 7%) · accuracy incidents allowed: zero · the date — eight months, hard · budget ~$1.8M · hypercare exit < 2 blockers/day.

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery (month 1)** — sponsor charter in week one (objectives, assumptions, success criteria, phase entry/exit criteria); interface inventory v0 from message logs; systems-impacted table with LOE per owner; the floor walked until I could follow receive → put-away → pick → ship unaided. *Exit bar:* charter signed by sponsor and Finance; every interface has a named owner.
- **Plan & Design (months 2–3)** — design sign-off pack; interface inventory v1 with a test cell per contract; conversion approach — masters → open orders → on-hand → in-transit as its own batch; mapping-table standard (data, not code); the 0.5% tolerance published with Finance before mock 1. *Exit bar:* council sign-off; tolerance signed; stories slotted by business criticality × effort.
- **Build & Test (months 4–7)** — QA demo schedule to DC Ops; UAT entrance memo (function testing done, conversion build done, test data handed off, pre-prod + perf ready) — QA could fail a build; three mock cutovers with written root causes by class: 7% → 1.8% → 0.3%; after the RF miss, the training plan and device-readiness table. *Exit bar:* mock 3 ≤ 0.5% → written go-live recommendation; training sign-off (slipped 1.5 weeks, date held).
- **Cutover & Go-Live (month 8)** — runbook; 72-hour transfer freeze (≥ the longest lane transit); conversion batches; post-load reconciliation; legacy read-only switch; the go/no-go call. the RF-device conversion — hundreds of devices caught in the pre-training device test — had already moved training 1.5 weeks while the date held; leadership was told the same day with the slip priced. *Exit bar:* post-load mismatch inside tolerance; ship confirms posting; zero accuracy incidents.
- **Hypercare / Close (4 weeks planned)** — blockers/day read daily; 30-day failback watch (legacy read-only); budget closed; exit memo with the single-point-dependency lesson. *Exit bar:* < 2 blockers/day sustained → exit week 3; ~3% under budget; pipeline programs started the next month.

Influence and ownership. Mine: the charter, the entrance/exit criteria, the interface inventory, the conversion approach, the mapping-table standard, the tolerance, the go/no-go recommendation and the fallback call; the team built, converted, tested and ran the floor; Finance co-owned the tolerance. Because the success criteria were written in week one and signed by sponsor and Finance, nobody negotiated the exit later. The RF miss is mine — I scored the task by effort when impact was what mattered — and it went upstairs the same afternoon with my name on the cause.

> **Designed the process; others own it now.** I designed the charter, the tolerance, the entrance criteria and the mapping-table standard; the team and Finance now run cutovers against them, and the standard outlived the program. **Trade-off put to leadership.** The recommendation to the sponsor outlined the competing metrics — the eight-month date and the $20M pipeline behind it vs training readiness and conversion variance — and held the date while training slipped 1.5 weeks and the 0.5% tolerance did not move.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY (CANON NUMBERS ONLY)

- **$** — ~3% under the ~$1.8M budget (~$54K, record); the $20M ROI pipeline unblocked the next month — ~$2.5M/month of slip (my division, modeled; not banked); ≈$875K *modeled* price of a 1.5-week go-live slip (my division of the $20M; not banked); ≈$0.1M *modeled* less inventory in dispute at 0.3% vs 0.5% on an illustrative $50M on-hand.
- **#** — hundreds of RF devices failed the conversion script in the pre-training device test (a three-to-four-day estimate that proved wrong); team 14 core + 6 DC Ops across two DCs (record).
- **%** — mock variance 7% → 1.8% → 0.3% against the 0.5% tolerance published with Finance before mock 1 (record).
- **Time** — eight-month deadline held; 72-hour in-transit freeze; legacy read-only for 30 days; training slipped 1.5 weeks while the date did not move; hypercare exited week 3 of 4 (record).
- **Customer** — zero accuracy incidents at cutover; ship confirms posting; post-load mismatch inside tolerance (record exit bars).
- **Quality** — mocks read by cause class, each removing a named defect category; failback rehearsed, never used; a what-if plan now required for every single-point dependency (record).

L6 LEVEL EVIDENCE — what the interviewer pattern-matches against the Amazon L6 functional rubric; every line is this story's canon, no new numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	An eight-month deadline across two DCs with no charter. I wrote the sponsor charter in week one — objectives, assumptions, success criteria, phase entry/exit criteria — and set the tolerance with Finance before anyone rehearsed.
Scope & influence	14 core + 6 DC Ops across two DCs; Finance co-owned the tolerance; QA could fail a build on my UAT entrance memo; the go/no-go recommendation and the fallback call were mine to the sponsor.
Execution trade-off + mechanism others now own	Date vs readiness: training slipped 1.5 weeks while the date held; a 72-hour transfer freeze (sized to the longest lane) bought conversion integrity. Mechanisms others own now: the 0.5% tolerance, the UAT entrance memo, and the mapping-table standard (data, not code).
Impact (long-term)	Eight-month deadline held; ~3% under the ~$1.8M budget; the $20M ROI pipeline unblocked the next month — ~$2.5M/month of slip (my division, modeled; not banked); zero accuracy incidents at cutover.
Process improvement (standard work institutionalized)	Three mock cutovers read by cause class (variance 7% → 1.8% → 0.3% against 0.5%); a 30-day failback watch with legacy read-only; a numeric hypercare exit (< 2 blockers/day sustained).
Complexity & consensus	hundreds of RF devices failed the conversion script in the pre-training device test — leadership was told the same day, training slipped 1.5 weeks, the date did not move.
Root cause at scale	The single-point-dependency lesson went into the exit memo; each mock removed a named defect category rather than fixing individual records, so the fix scaled to the whole conversion.

PROBING — FIVE FACETS, THEN THE HARDEST FOLLOW-UPS NEW

THE FIVE FACETS — WHERE EACH ONE LIVES IN THIS STORY

1 · Data analysis. Grain: SKU × location × unit of measure; units in flight by lane. Data: legacy WMS and JDA conversion output, message logs for the interface inventory, three mock result sets. Cuts: variance by cause class (UoM, location names, status vocabularies, in-transit timing). Revealed: one mapping class — UoM, factor 12 on ~1% of SKUs — dominated the 7%.

2 · Solution design. Options: (A) big-bang cutover with tolerance TBD; (B) tolerance published before mock one, mocks read by cause class, freeze and failback (chosen); (C) parallel run. Chose B — the tolerance belongs to Finance and me before the test, not after.

3 · Math & data logic. M = Σ|Δ| / Σ ERP on-hand; 7.0% → 1.8% → 0.3% ≤ 0.5%; freeze F = 72 h ≥ max lane transit; slip price $2.5M / 30 = $83,333/day; 10.5 days → $875K (price of a 1.5-week go-live slip).

4 · Implementation. Five gated phases over eight months: charter week one; interface inventory with a test cell per contract; three mocks; 72-hour freeze; legacy read-only 30 days; device-readiness in training entrance criteria; hypercare exit week 3 at < 2 blockers/day.

5 · Probe questions. The six answered above in the Probing block, and the three trap drills below.

FACET 5 — PROBE QUESTIONS (CHALLENGE Q&A TUNED TO THIS INTERVIEWER)

Infra — Why publish a tolerance before you knew you could hit it?

So the number belonged to Finance and me before the test, not after. Mock one's 7% was the price; mock three's 0.3% was worth it — and the tolerance was never renegotiated.

Infra — How do you read a mock?

Never by the headline alone. Every delta got a root-cause class — units of measure, location drift, status vocabularies, then in-transit timing. If the total shrank without a named cause, the mock was not evidence. 7 → 1.8 → 0.3 each removed a category, and the fixes were mapping tables as data, not code.

Infra — Hundreds of RF devices failed the device test before training. Why not move the date?

Because inventory was inside tolerance — the failure was device conversion, not data — and the training criterion could move without moving the go-live. I held the date, let training slip 1.5 weeks, and took the miss upstairs the same afternoon with my name on the cause.

Infra — What was the freeze and why 72 hours?

A 72-hour in-transit freeze, set at or above the longest lane transit, so in-transit could be converted as its own batch with Σ legacy = Σ JDA — the class that took mock two from 1.8% to 0.3%. Legacy stayed read-only for 30 days as the failback.

Infra — The $875K avoided slip — are you banking it?

No. It is modeled arithmetic — 10.5 days at about $83K a day, from my division of the $20M over eight months — on a slip that did not happen; it is the price that made holding the date the obvious call. What I would measure is the pipeline's first program start against plan, which was the next month.

Infra — Lesson, and what rule did you leave behind?

Any single-point dependency in front of an exit criterion gets a what-if plan regardless of estimated effort. Differently: dual-path device conversion on day one, and a device model × OS × script pass/fail table before training week.

THE MATH — FOUR-TABLE DERIVATION (FORMULA → SUBSTITUTION → RESULT) NEW

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Mock 1 variance	`M = Σ|Δ| / Σ ERP on-hand = 140,000 / 2,000,000 = 7.0%`	illustrative units on record percentages	7.0% — 14× the tolerance
2	Dominant cause — UoM	`a case booked as 12 eaches creates 12 − 1 = 11 units of error per case; factor 12 on 1% of SKUs`	record mechanism	one mapping class dominates the 7%
3	Second cause — in-transit timing	`transfers in flight at snapshot counted at neither end or both`	record mechanism	the timing class
4	The stakes	`$20M pipeline gated; about $2.5M per month of slip`	$20M record; $2.5M/month = my division, modeled	every day priced

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Tolerance signed first	`gate: M ≤ 0.5%, signed with Finance BEFORE mock 1`	never renegotiated (record)	the yardstick fixed in advance
2	UoM fix as data	`mock 2: M = 36,000 / 2,000,000 = 1.8%`	mapping tables (UoM, location, status) as data, not code (record % on illustrative units)	7.0% → 1.8%
3	Freeze + own batch	`freeze F = 72 h ≥ max lane transit; in-transit converted as its own batch with Σ legacy = Σ JDA; mock 3: M = 6,000 / 2,000,000 = 0.3%`	record % on illustrative units	1.8% → 0.3%
4	Gate evaluated	`0.3% ≤ 0.5% → go`	as a written recommendation (record)	go-live recommended
5	RF-device miss	`script failed on refreshed RF hardware (hundreds of devices); training sign-off +1.5 wk; go-live date holds`	record (Apple G2; master S18) — count, timing and fallback CONFLICT, see box	go-live on the date
6	Hypercare exit	`blockers/day < 2 sustained — the charter's own number`	record	exited week 3 of 4

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Cutover variance (three mocks)	7.0%	1.8% → 0.3% vs 0.5% tolerance	record
2	Go-live date	at risk from the RF miss	held — 8 months end to end	record
3	Budget	~$1.8M	~3% under	record
4	$20M pipeline	gated	starts on time	record

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Budget result	`$1,800,000 × 3% = $54,000`	record	≈$54K under budget
2	Slip price	`$2,500,000 / 30 = $83,333/day`	$20M pipeline gated (record) ÷ 8 months = $2.5M/month — my division, modeled; not banked	≈$83K/day
3	Critical-path slip avoided	`1.5 wk × 7 = 10.5 days; 10.5 × $83,333 = $875,000`	price of a 1.5-week go-live slip at $83,333/day (modeled — my division of the $20M; master S18); not banked	≈$875K — avoided, not banked
4	Fallback cost paid	`≈$45K paper-pick; $875,000 / $45,000 ≈ 19`	master-packet model only (paper-pick on a subset of devices); NOT in Apple G2 — do not say aloud	≈$45K (master only)
5	Dispute delta	`(0.5% − 0.3%) = 0.2%; × $50,000,000 = $100,000`	illustrative on-hand (modeled)	≈$0.1M one-time less in dispute

SOLUTION FLOW — THE SYSTEM & DATA MAP NEW

```
[Legacy WMS (RP)]  --extract-->  [Mapping tables as DATA: UoM | location | status]
      |                                  |
      | 72-h in-transit freeze (>= longest lane transit)
      v                                  v
[conversion batches: masters -> open orders -> on-hand -> IN-TRANSIT as its own batch]
      |                                  |
      v                                  v
[JDA WMS, two DCs] <-- interface inventory: ERP <-> WMS <-> 3PL <-> carrier (owner + test cell per contract)
      |
post-load reconciliation: M = sum|delta| / sum on-hand  vs tolerance 0.5% (signed with Finance before mock 1)
      |
go/no-go -> legacy READ-ONLY 30 days (failback) -> RF devices: conversion script failed on refreshed hardware
      |                                                  -> training sign-off +1.5 wk; go-live date held (see conflict box)
hypercare: blockers/day < 2 sustained -> exit week 3
```

SENSITIVITY — LOW / BASE / HIGH NEW

INPUT	LOW	BASE	HIGH
Average unit cost (illustrative)	$15	$25	$40
Paper-pick slowdown (master-packet model; not Apple G2)	15%	25%	40%
DC labor rate (benchmark)	$25/h	$30/h	$35/h
Inventory dispute avoided (0.5% → 0.3%)	~$60K	~$100K	~$160K
Paper-pick fallback cost (master only)	~$23K	~$45K	~$84K
Total modeled	~$40K net	~$55K net	~$75K net

SPOKEN STATEMENT NEW

> “The record numbers first: on time, about $54K under a $1.8M budget, and the $20M pipeline started the next month, where every month of slip was worth about $2.5M on average — my division of the twenty million over eight months, not banked. A slip of the 1.5 weeks the training criterion moved would, had it moved the go-live, have cost about $875K — so I held the date and moved training, and said so straight. The modeled part is smaller and I’ll label it: landing at 0.3 percent against a 0.5 tolerance meant about $100K less inventory in dispute at cutover on an illustrative $50M on-hand, and at mock one’s 7 percent that would have been $3.5M. The date, the budget, the variance and the pipeline are measured; the on-hand value is my model.”

IF CHALLENGED NEW

“Where does $50M of on-hand come from?”

It’s illustrative, two million units at $25, chosen so the percentages become dollars; the record gives me 0.3 percent, not the balance sheet. I’d firm it up with the actual ERP on-hand valuation at the freeze snapshot, which Finance already had.

“The $875K avoided slip is a counterfactual.”

Yes — record arithmetic on a slip that did not happen, so I never bank it; it is the price that made the fallback the obvious call. What I’d measure is the pipeline’s first program start against plan, which was the next month.

“What did the RF miss actually cost?”

The record is the 1.5 weeks of training sign-off — SME windows were scarce — and a go-live date that held. I have not priced a fallback and I will not invent a number; the master packet carries a modeled paper-pick figure that my 2022 notes do not, so I do not say it.

Where this lands at Amazon. Cutover discipline in its most literal form — a tolerance published with Finance before the first rehearsal, mocks read by cause class, a freeze sized to the longest lane, a tested failback, a numeric hypercare exit nobody can negotiate, and a rehearsed contingency that fired on the day. Reliability (0.3% against 0.5%, zero accuracy incidents), responsiveness (the decision the same day), cost efficiency (~3% under), the $20M pipeline on the date.

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE WITH S18

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Tell me about a time something went wrong at go-live.	Bias for Action / Ownership	The RF miss: hundreds of devices in the pre-training device test; leadership told the same day; training slipped 1.5 weeks, the date did not.	Never "400 devices failed" or a ~100/~400 ratio; do not blame the vendor script — the scoring miss was mine.

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Tell me about a time you set a standard others thought was too strict.	Insist on the Highest Standards	0.5% published with Finance before mock one; mock one at 7% was the price; never renegotiated.	S2's 98% gate is the primary for this LP — use it first if both land here, S18 second.
Tell me about learning something new fast.	Learn and Be Curious	Never run a WMS migration; charter in week one; the floor walked unaided by end of month one; the mocks were where I proved it.	Do not overclaim WMS configuration — the team converted and built.
Tell me about a time you delivered on a hard date.	Deliver Results	Eight months, both DCs, 0.3% vs 0.5%, ~3% under, $20M pipeline unblocked the next month.	Never bank the $875K or the $2.5M/month — slip avoided.
How do you design a freeze / failback for a systems cutover?	Functional — migration design	Freeze ≥ longest lane transit; in-transit as its own batch; legacy read-only 30 days; rollback triggers as numbers (mismatch > 0.5% for 2 days; ship-confirm posting failing > 2 h).	Keep budget at ~$1.8M and slip at ~$2.5M/month (loop-packet conflict).
What did you miss and what did you change?	Ownership	RF conversion on the log as a task, not a risk; the rule left behind: any single-point dependency in front of an exit criterion gets a what-if plan.	Do not soften it — "the miss is mine."

BEHAVIORAL PACK — FOUR SEPARATE 90-SECOND STAR ANSWERS, EACH FROM A DIFFERENT MOMENT OF THE STORY NEW

OWNERSHIP · AIQB Q2 **Q1. "Describe a time when you didn't think you were going to meet a commitment you promised."**

The miss was mine, and I said so straight. The devices team called the RF conversion three to four days and straightforward, and I planned it that way — low effort, low attention. Just to be sure, I scheduled a device test with engineering days before training, and the upgrade script failed: the refreshed RF hardware did not run the old code. Hundreds of devices, and with key people on COVID night shifts the manual conversion could not finish in time, so I told leadership straight: training sign-off, a go-live exit criterion, slips a week and a half. The root cause was my risk model — I scored the task by effort, not impact, so a single-point dependency in front of an exit criterion had no what-if plan. The date held and the migration landed on time, about 3% under budget. The rule I left behind: every cross-functional dependency gets a what-if and a mitigation whatever the effort estimate, and device readiness moved into training's entrance criteria — proven devices, not promised ones.

Number to land: training +1.5 weeks · date held · ~3% under budget · **Pivot to NACF:** At NACF a single-point dependency in front of a launch — one carrier, one door, one scanner model — gets a what-if plan regardless of size. · **Do NOT say:** an exact device count — say 'hundreds' (the 2022 notes record ~400 in one telling and ~100 in another); that the vendor script was the cause.

BIAS FOR ACTION · AIQB Q4 **Q2. "Tell me about a time when you had to gather information and respond immediately to a situation."**

I ran a check I did not have to run, and it failed. Training sign-off depended on hundreds of RF guns, printers and workstations converting, and the devices team said a few days. Just to be sure, I scheduled a device test with engineering days before training. The script failed on the refreshed hardware. The decision that mattered was fast because the options fit on one page: manual conversion on COVID night shifts could not finish before training, so something had to move, and the choice was which date. Training moved a week and a half; the go-live did not — and I told leadership that straight, with my name on the cause. Then I changed the system: device readiness went into training's entrance criteria, and the habit generalized into dress rehearsals for everything on the critical path — on UDC it became the RF-device proof-of-concept before cutover week.

Number to land: training +1.5 weeks; go-live date held · **Pivot to NACF:** At NACF a rehearsal a week before the first live trailer is how a launch absorbs a surprise on the day — I would rehearse the dependency, not just the plan. · **Do NOT say:** that I improvised; or a fallback or dollar figure the 2022 notes do not carry.

LEARN AND BE CURIOUS · AIQB Q2 **Q3. "Describe a time when you took on work outside of your comfort area. How did you identify what you needed to learn to be successful?"**

I had never run a WMS migration, and the deadline was eight months. I wrote the charter in week one — success criteria, assumptions, entry and exit criteria — so the destination existed before my knowledge did. Then I spent month one on the floor, walking receive, put-away, pick and ship until I could follow a unit through the building unaided, and reading the message logs to build the interface inventory with an owner and a test cell per contract. The mocks were where I proved the learning: each delta got a root-cause class — units of measure, location names, status vocabularies, in-transit timing — so I was learning by removing categories, not by reading documentation. By the third mock the variance was 0.3% against a 0.5% tolerance. I did not claim to configure the system; the team converted and built.

Number to land: month 1 on the floor; 7% → 1.8% → 0.3% · **Pivot to NACF:** At NACF I would walk the dock-to-stock path in my first weeks before proposing a change to it. · **Do NOT say:** that I configured JDA or converted the data myself.

INSIST ON THE HIGHEST STANDARDS · AIQB Q1 **Q4. "Describe a time when you refused to compromise your standards around quality/customer service, etc."**

I published the reconciliation tolerance — 0.5% — with Finance before the first mock. So the number belonged to Finance and to me before the test, not after. Mock one came in at 7% — fourteen times the bar — and that was the price. I did not renegotiate; I read the mock by cause class: units of measure were the dominant class — a case booked as twelve eaches is eleven units of error — then location names and status vocabularies. The fix was mapping tables as data, not code. Mock two: 1.8%. Mock three: a 72-hour in-transit freeze and in-transit converted as its own batch, 0.3%. The written go recommendation came off mock three, inside the tolerance. The tolerance was never renegotiated, and the exit bar for hypercare — under two blockers a day — was in the charter in week one, so nobody negotiated that either.

Number to land: 0.5% published first; 7.0% → 1.8% → 0.3% · **Pivot to NACF:** At NACF I would publish the reconciliation tolerance — dock-received vs system-available — before the first mock receipt. · **Do NOT say:** that 7% was a surprise to Finance; they signed the bar first.

SAME STORY, THREE ANGLES — DATA · CONFLICT/INFLUENCE/BACKBONE · FAILURE-LEARNING NEW

DATA ANGLE · DIVE DEEP

"Seven percent, one point eight, point three — each mock removed a named category."

Headline metric: M = 140,000 / 2,000,000 = 7.0% → 0.3%

Mocks read by cause class: UoM (12 → 11 units of error per case) first, then in-transit timing as its own batch. If the total shrank without a named cause the mock was not evidence. Units are illustrative; the percentages are the record.

CONFLICT / INFLUENCE ANGLE · INSIST ON THE HIGHEST STANDARDS

"I published a tolerance with Finance before I knew I could hit it."

Headline metric: 0.5% never renegotiated

Finance co-owned the number; the sponsor signed the charter in week one; leadership was told the same day the training criterion slipped 1.5 weeks — the date held, the tolerance did not move.

FAILURE / LEARNING ANGLE · OWNERSHIP

"A three-day device task broke the training gate, and I had scored it by effort."

Headline metric: training +1.5 weeks; date held; ~3% under

Impact, not effort, is the score; a single-point dependency in front of an exit criterion gets a what-if plan. The test I ran just to be sure saved the go-live, not the training gate. Differently: a device model × OS × script pass/fail table at refresh. The rule shows in the mocks: 7.0% → 1.8% → 0.3%.

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS, WITH NUMERIC ANSWERS NEW

How do you know the three mocks measured the same thing?

Same formula, same denominator (Σ ERP on-hand), same scope; the changes between mocks were named cause-class fixes. Units are illustrative; the percentages are the record.

Say: *"Same formula and denominator each time, and every change between mocks was a named cause class — if the total shrank without a named cause I did not count it."*

"A week and a half on training — that is a small failure. Give me a bigger one."

Fair. The bigger one is the Elementum UAT that crashed (Apple G1) — a lost sign-off. I keep this one because its lesson transfers best: the failure class that hits mature programs is not the big risk everyone watches, it is the three-day task nobody did a what-if on. The size of the slip is not the point; the blind spot is.

Say: *"A week and a half is small; the blind spot is not — impact decides the attention a task gets, never its effort estimate."*

What is the number that would have changed your mind on go?

Mock three above 0.5%, a failed freeze or a failback I could not describe per interface. The RF failure was a different class: it moved training, not the go.

Say: *"Mock three over half a percent — that single number was the go/no-go."*

20-SECOND VERSION + NACF BRIDGE NEW

20-second version. At Sephora I took two DCs from a legacy WMS to JDA in eight months, ~3% under a ~$1.8M budget, by publishing a 0.5% reconciliation tolerance with Finance before mock one and reading three mocks by cause — 7%, 1.8%, 0.3% — and when the RF device conversion failed its pre-training test I told leadership straight — training slips a week and a half, the date holds — and made what-if plans a rule.

NACF bridge. NACF's inbound ramp is a migration of a different kind — a new FC's dock, UPH and cube all go live together — and the same discipline applies: publish the tolerance before the first mock, size the freeze to the longest lane, rehearse the fallback, and give single-point dependencies a what-if. CAP-A's 5 doors at an 85% ceiling are the slack that lets a day-one surprise be absorbed without moving the date.

U1 — The node × channel × bucket-transition matrix — one regression asset that proved every physical move on the floor lands in exactly one system bucket NEW

LPs this story serves here: Invent and Simplify (primary — one rule, one asset) · Dive Deep (primary — event traces, the 836-row log) · Insist on the Highest Standards (what "tested" means) · Earn Trust (QA demoed to DC Ops in build) · Success and Scale (backup — a new node is a row, not a project)
Process family: Make / Deliver — test and acceptance design for a comingled node; physical-event ↔ system-bucket integrity; regression asset reused through hypercare and the monthly release train

Honesty label. I owned the matrix design and its assertions as program owner of the location/inventory model; BlueYonder, ISM and platform teams built to it, QA ran it and owned the gate, DC Ops confirmed in UAT. The rule, the test families, the entry gate and the issues-log numbers are record. The cell counts (6 node-channel pairs, 14 events, 61 live cells) are **illustrative** VERIFY-WITH-RAJESH — confirm the real matrix size before saying a count aloud. The ISM/S4 bucket formula is the same program artifact as Lan's S1; here it is told from the floor-event side. Never claim configuring S/4, ISM or BlueYonder.

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH

Invent and Simplify. About a dozen impacted systems and about thirty build tracks ran on one rule — every event maps to exactly one bucket — and one entry gate: no story enters QA without a matrix cell reference.

Dive Deep. I read one SKU, one day, event by event: an event landing in zero buckets promises 3 units that are gone (560), in two buckets hides 3 (554); the right answer is 557.

Insist on the Highest Standards. "Tested" meant every live cell asserted before/after with numbers, three dated E2E days with every function in one room, and Blocker + Critical open = 0 at each go/no-go.

Earn Trust. QA demoed each matrix family to DC Ops and planners during build, so UAT was confirmation, not discovery.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. At the Utah DC one physical pool had to serve three node types and two channels, and "available" had to move correctly on every physical event — a store ring, a pick, a pack, a ship confirm, a receipt, a transfer, an adjustment — across about a dozen impacted systems and about thirty build tracks, with zero customer-facing incidents allowed. **Task.** I owned the node × channel × bucket-transition matrix: the design and the regression asset the whole program tested against. **Action.** Discovery: a bucket inventory with exactly one owning system per bucket, and an event inventory — POS flash sale, omni pending, ship confirm, the S/4 Aggregation# posting, and SAP movement types 101, 311, 601, 701 and 702. Plan & Design: one rule — every event maps to exactly one bucket; a reversal must reference its original; a replayed event is a no-op. Build & Test: every cell carries a before/after assertion with numbers, and no story enters QA without a cell reference; three dated E2E days ran the whole flow in one room. Cutover: January and May go/no-go off counted rows — Blocker + Critical open = 0. Hypercare: ISM-vs-MB52 drift at zero SKUs on consecutive days; four in-transit cells and a de-aggregation family added from what the floor taught us. **Result.** Primary metric: customer-facing incidents — zero through both go-lives, with 836 issues logged, 441 of them Blocker or Critical (52.8%), 85.4% closed. The dollars are a what-if, labeled: break-even is about 1.8 escaped cell-classes a year.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — One physical pool, three node types (Store, Retail DC, Dotcom DC), three working definitions of "available," and a physical floor that generates events the books must follow: pick reserve, ecom pick and pack, ship confirm, receipt, transfer, adjustment. Left to the happy-path E2E, an event can land in zero buckets (oversell) or two (undersell) and nobody sees it until a customer does.

T — Own the design and the regression asset: which events exist, which bucket each one moves, what the numbers must be before and after, and the gate that stops an unproven story from entering QA. None of the systems reported to me; ~30 build tracks ran under one issues log; stories were slotted by business criticality × effort.

Baselines on the table: three working definitions of "available" · customer-facing incidents allowed: 0 · Blocker + Critical open = 0 at every go/no-go · four epic modules (reserve module, AFS engine, SNB, control screens) · per-environment workbooks Dev 310 / QA 255 / Perf 200 / Prod 221 rows · issues log 836 rows by program end.

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery (3/29 → 4/30)** — profiled both books; built the bucket inventory with one proposed owning system per bucket; built the event inventory — POS flash sale, omni pending, ship-to-home confirm, S/4 Aggregation# posting, and MSEG movement types 101/311/601/701/702 as events. *Exit bar:* every bucket owned by exactly one system; every event named; sessions closed 4/30.
- **Plan & Design (5/15 → 8/14)** — wrote the exactly-one-bucket rule, the reversal-references-original rule and the idempotency key into the FSD; kept Merch Reserve and Lost/Found outside S4_Avail so no double-subtract path exists; drafted the test-matrix skeleton. *Exit bar:*

FSD signed 8/14 (record) with every bucket owned by exactly one system (the master's discovery exit bar).

- **Build & Test (Aug → Jan/Apr)** — authored each cell with before/after assertions; slotted epics per module; enforced "no story enters QA without a matrix cell reference"; closed SIT contract defects before UAT; ran the dated E2E days — Inbound 11/22, Dotcom 12/20, Retail 1/30. *Exit bar:* 0 open SIT contract defects; E2E green on three dates; Blocker + Critical open = 0.
- **Cutover & Go-Live (January; May 1 → Jul 1)** — wrote the go/no-go recommendation from counted rows; the publish switch (OMS reads published AFS, never computes); reserve-copy invariants checked per SKU. *Exit bar:* no SKU with two published AFS values; Negative AFS clean at T+1; rollback never fired.
- **Hypercare / Close (Jun → Jul)** — daily ISM-vs-MB52 drift; matrix grew from what the floor taught — four in-transit regression cells and the de-aggregation family (n lines · missing line · duplicate header) per event source. *Exit bar:* drift = 0 SKUs on consecutive days; matrix and control-owner map handed to the monthly release train.

Influence and ownership. Mine: the bucket inventory, the event inventory, the exactly-one-bucket rule, every cell's assertions, the entry gate and the go/no-go recommendation. Built by others: BlueYonder, ISM and platform teams; QA ran the cells and owned the gate; DC Ops and planners confirmed in UAT because QA had already demoed each matrix family to them during build.

> **Designed the process; others own it now.** The matrix, the entry gate and the regression families are standard work now: QA owns the gate, the control owners own the screens, and every later rule change enters as rows. **Trade-off put to leadership:** the date versus the bar — the gate was Blocker + Critical open = 0 and a countable cell list, not a feeling, so the go/no-go was arithmetic.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY

- **$** — no record dollar. The what-if (modeled, **illustrative**): 30,000 oversell-exposed incidents/yr ÷ 61 live cells = 491.8 per cell × $30 = ≈$14.8K/yr per escaped cell-class against ≈$26.8K one-time to author and run the matrix — break-even ≈1.8 escaped cell-classes. Not claimed as a saving.
- # — 836 rows in the issues log, 164 Blocker + 277 Critical = 441 (52.8%), 714 closed (85.4%) · 4 in-transit regression cells + a 3-case de-aggregation family per event source · E2E days 11/22 · 12/20 · 1/30 (record).
- **%** — Blocker + Critical open = 0 at each go/no-go; daily drift 0 SKUs on consecutive days at hypercare exit (record).
- **Time** — FSD signed 8/14 · three dated E2E days · January and May go-lives · hypercare exit week 3 of 4 (record).
- **Customer** — zero customer-facing incidents through both go-lives; no SKU with two published AFS values (record).
- **Quality** — every live cell asserted before/after; every event maps to exactly one bucket; a replayed event is a no-op (record design).

L6 LEVEL EVIDENCE — every line is this story's record or labeled model, no new canon numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	No agreed way to prove physical events and system buckets agreed. I defined the events, the buckets and the rule, and made "tested" countable.
Scope & influence	~30 build tracks in other orgs; QA owned the gate; DC Ops and planners confirmed in UAT; the entry rule moved every track onto one asset without anyone reporting to me.
Execution trade-off + mechanism others own	Coverage versus speed: one cell reference per story, assertions with numbers. Mechanism others own now: QA's gate and the matrix families in the monthly release train.
Impact	Zero customer-facing incidents through both go-lives; 441 Blocker/Critical findings dispositioned before customers saw them.
Process improvement	Rule changes (the in-transit rule, de-aggregation) enter as new cells, not new projects; a new node or channel is a matrix row.
Complexity & consensus	Three node types, two channels, about a dozen impacted systems, three signing orgs — one FSD, one matrix.
Root cause at scale	Defects clustered at seams where two systems used different grain; the fix was a rule at the seam, not 441 individual patches.

PROBING — FIVE FACETS, THEN THE HARDEST FOLLOW-UPS NEW

THE FIVE FACETS — WHERE EACH ONE LIVES IN THIS STORY

1 · Data analysis. Grain: SKU × node × channel × bucket × event. Sources: the bucket inventory (both books), the event inventory (POS, OMS, WMS, S/4 movement types 101/311/601/701/702), the 836-row issues log (severity, owner, function). Cuts: events by bucket cardinality (0 / 1 / 2), defects by severity and by seam. Revealed: the log shows where the book is heavy — 523 of 836 rows (62.6%) sit in the Outbound, Retail and Inbound flows, where an event crosses from one system to the next — but it carries no cell tag, so the matrix's yield against it is not measured.

2 · Solution design. Options: (A) happy-path E2E only; (B) per-system unit tests; (C) an event × node-channel matrix with before/after assertions. Chose C — A and B each pass while the seam between systems is wrong. Why: the oversell bug is a seam bug, and a matrix makes coverage countable and gateable.

3 · Math & data logic. AFS = Basis − PickRes − EcomPick − EcomPack − SNB; Basis = min(S4_Avail, WMS_OnHand); cardinality rule: 0 buckets → +3 error (560), 2 buckets → −3 error (554), exactly 1 → 557; replay no-op; drift = ISM.S4_Avail − MB52 = 0; de-aggregation Σ per-line COGS = posting COGS to the cent.

4 · Implementation. Phases and gates above; owners: me (rule, cells, go/no-go), QA (gate), DC Ops/planners (UAT), control owners (screens). Controls: entry gate, E2E days, Blocker + Critical = 0, drift = 0. Risks: vocabulary drift, feed latency, override abuse (the register's top three).

5 · Probe questions. Below: why a matrix, how you know it mattered, what it missed, what 61 cells cost, and the three trap drills.

FACET 5 — PROBE QUESTIONS (CHALLENGE Q&A TUNED TO THIS INTERVIEWER)

Infra — why a matrix and not just more E2E days?

E2E proves the paths someone thought to walk; a matrix lists the cells nobody walked. We ran both — three dated E2E days — but the entry gate (no story enters QA without a cell reference) is what made coverage countable. The log tells you what broke; the matrix tells you what you never tried.

Infra — how do you know the matrix is what kept incidents at zero?

I can't isolate it and I won't claim to. The record is: zero customer-facing incidents, 441 Blocker/Critical rows dispositioned, Blocker + Critical open = 0 at each go/no-go. The number that would change my mind is a customer-facing incident traced to an event that had no cell.

Infra — what did the matrix miss?

My own first in-transit rule. The cells asserted the rule I wrote — "never promise in-transit" — and it passed every cell while starving dotcom of fast movers one day from the building. The fix added four cells and a back-test requirement: a matrix asserts the rule; only history tells you the rule is right.

Infra — what is a cell, concretely?

One event at one node-channel pair with a before state, an after state and the numbers: e.g. a store rings 3 units at 10:02 — AFS 560 → 557, SNB 40 → 43, replay at 10:04 → 557, overnight posting → S4_Avail 957, drift 0.

Infra — your 61-cell count — real?

No. Six node-channel pairs, 14 events, 84 candidate cells minus 36 structurally impossible = 48, plus 4 in-transit cells and a 3-case family on 3 event sources = 61 — all illustrative sizing. The record is the rule, the families and the log; I would confirm the actual count before quoting one.

Infra — what would you do differently?

Tag every issues-log row with its matrix cell from day one. I can say every story needed a cell reference; I cannot say what share of the 441 Blocker/Critical rows was found by a cell assertion rather than an E2E room. That is the one number that would prove the matrix's yield.

BUSINESS IMPACT MODEL — KPI DRIVERS, BASELINE → AFTER

DRIVER	BASELINE	AFTER	$ / EFFECT	BASIS
Event → bucket cardinality	unverified (0 or 2 possible)	exactly 1, asserted per live cell	±3 units per event on the worked SKU	record design
Working definitions of "available"	3	1 signed AFS	—	record
Blocker + Critical open at go/no-go	441 logged (52.8% of 836)	0 open at each go/no-go	—	record
Issues closed	836 rows	714 closed (85.4%)	—	record
Customer-facing incidents	0 allowed	0 through both go-lives	what-if ≈$14.8K/yr per escaped cell-class	record / modeled what-if

THE MATH — FOUR-TABLE DERIVATION (FORMULA → SUBSTITUTION → RESULT) NEW

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Working definitions	`definitions = 3 (Store · Retail DC · Dotcom DC)`	record	3
2	Definition A over-promise	`channel reads raw S/4: promises 1,000; truly promisable 560; 1,000 − 560 = 440`	S1 worked SKU (illustrative); committed buckets invisible	440 units over-promised
3	Definition B over-promise	`channel reads WMS on-hand: 980 − 560 = 420`	same SKU; same blind spot	420 units over-promised
4	Units already spoken for	`Σ buckets = 200 + 120 + 60 + 40 = 420`	PickRes 200 · EcomPick 120 · EcomPack 60 · SNB 40 (illustrative)	420 units
5	Event lands in 0 buckets	`store rings 3; AFS stays 560; true 560 − 3 = 557; error = 560 − 557 = +3`	illustrative event	+3 oversell exposure
6	Event lands in 2 buckets	`AFS = 560 − 3 − 3 = 554; error = 557 − 554 = −3`	double-subtract path (illustrative)	−3 hidden units

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
7	Issues log	`164 Blocker + 277 Critical = 441; 441 / 836 = 52.8%`	record (issues log)	52.8% high-severity

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Cell: supply basis	`Basis = min(1,000, 980) = 980`	asymmetric lower-of-two (record design)	980
2	Cell: AFS	`AFS = 980 − 200 − 120 − 60 − 40 = 560`	AFS = Basis − PickRes − EcomPick − EcomPack − SNB	560
3	Cell: floor above book	`Basis = min(1,000, 1,020) = 1,000; AFS = 1,000 − 420 = 580`	WMS 1,020 → OOB = −20 (illustrative)	580, not 600
4	Cell: store ring	`AFS = 560 − 3 = 557; SNB = 40 + 3 = 43`	one event → one bucket	557 / 43
5	Cell: replay	`replayed key → no-op; AFS = 557 − 0 = 557`	idempotency key (record design)	557
6	Cell: overnight posting + drift	`S4_Avail = 1,000 − 43 = 957; drift = 957 − 957 = 0`	tolerance 0 — a non-zero drift is a Sev	0
7	Cell: de-aggregation	`COGS_i = $300 × q_i / 12 → $75 + $50 + $100 + $25 + $50 = $300`	posting q = 12, C = $300; five lines (illustrative); last line absorbs rounding	$300.00 to the cent
8	Cell: late line	`SNB = 12 − 10 = 2 → aged row on the 24 h report`	one line (q = 2) late (illustrative)	2
9	Cell: in-transit lane	`Promisable = 120 × 1[0.4 ≤ 0.49] × 1[97% ≥ 95%] = 120 × 1 × 1 = 120; failing lane 80 × 0 = 0`	σ ≈ 0.3 d, window ≈ 0.49 d (record promise math); lane values illustrative	120 / 0
10	Sizing of the matrix	`6 pairs × 14 events = 84; 84 − 36 = 48; 48 + 4 + (3 × 3) = 61 live cells`	**illustrative** counts; 4 and the 3-case family are record	61

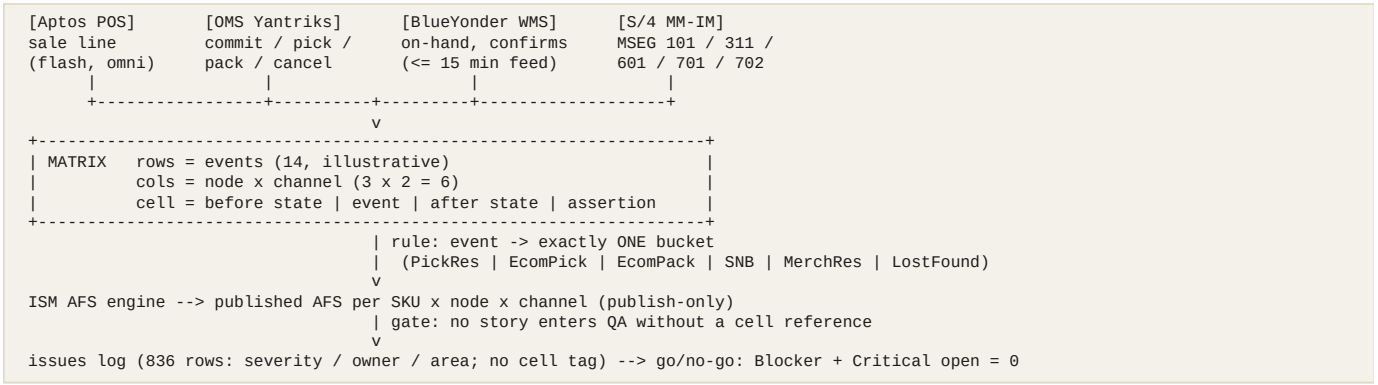

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Working definitions of “available”	3	1 signed AFS	record
2	Event → bucket cardinality	0 or 2 possible	exactly 1 on every live cell	record design
3	Blocker + Critical open at go/no-go	441 logged of 836	0 open	record
4	Issues closed	0 of 836 at kickoff	714 of 836 = 85.4%	record
5	Customer-facing incidents	0 allowed	0 through both go-lives	record
6	Drift (ISM vs MB52)	unmeasured	0 SKUs on consecutive days	record

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Oversell-exposed incidents	`30,000,000 × 0.10% = 30,000/yr`	S1’s illustrative orders × benchmark rate (0.05–0.25%)	30,000/yr
2	Cost per incident	`$6 + $4 + $19 + $1 = $30`	CS contact · refund · lost margin · goodwill (benchmark)	$30
3	Exposure per live cell (uniform)	`30,000 / 61 = 491.8 incidents`	assumes uniform exposure across 61 cells (illustrative)	491.8/yr
4	Dollars per escaped cell-class	`491.8 × $30 = $14,754`	modeled what-if; not claimed	≈$14.8K/yr
5	Cost to author + run the matrix	`61 × 4 h = 244 h; 244 × $110 = $26,840`	4 h per cell (illustrative); $110/h engineering rate (modeled, as S5)	≈$26.8K one-time
6	Break-even	`$26,840 / $14,754 = 1.8`	escaped cell-classes per year to pay for the matrix	≈1.8 cell-classes

SOLUTION FLOW — THE SYSTEM & DATA MAP

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Live cells (at 4 h × $110/h)	48 → $21.1K	61 → $26.8K	80 → $35.2K
Hours per cell (at 61 cells)	2 h → $13.4K	4 h → $26.8K	6 h → $40.3K
Oversell-exposed incidents / yr	15,000 (0.05%)	30,000 (0.10%)	75,000 (0.25%)
$ per escaped cell-class (÷ 61 × $30)	$7.4K	$14.8K	$36.9K
Break-even escaped cell-classes (at $26.8K)	3.6	1.8	0.7

SPOKEN STATEMENT

> “What I can prove is the rule and the gate: every physical event maps to exactly one bucket, and no story entered QA without a cell reference. Through both go-lives there were zero customer-facing incidents, with 836 issues logged — 441 Blocker or Critical, 52.8% — and 714 closed. What I cannot prove is how many of those the matrix caught versus the E2E rooms. The dollar view is a what-if on illustrative inputs: if the matrix keeps about two cell-classes a year from escaping, it has paid for itself.”

IF CHALLENGED

“Your cell count is invented.”

The design counts are illustrative sizing and I label them that way; the rule, the three de-aggregation cases, the four in-transit cells and the log are record. I would pull the real matrix from the QA workbooks before quoting a count.

“A matrix is shelfware — how do you know it was used?”

The entry gate: a story could not enter QA without a cell reference, and QA owned the gate and could fail a build. Use is enforced by the workflow, not by goodwill.

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Tell me about a time you simplified a complex process.	Invent and Simplify	One rule (event → exactly one bucket), one asset (the matrix), one gate (cell reference to enter QA) across about a dozen impacted systems.	Do not quote 61 as the real count.
Tell me about a time you dug into the data to find a root cause.	Dive Deep	Event traces on one SKU: 0 buckets → 560, 2 buckets → 554, 1 bucket → 557; defects clustered at seams.	Never claim the matrix alone kept incidents at zero.
What does ‘tested’ mean to you?	Insist on the Highest Standards	Every live cell asserted with numbers; three dated E2E days; Blocker + Critical open = 0.	Skip the Kafka/ESB topology unless asked.
How do you test a launch at scale?	Functional — launch readiness	Coverage countable by cell; QA owns the gate; counted rows at go/no-go.	Never ‘I configured ISM’.

BEHAVIORAL PACK — FOUR SEPARATE 90-SECOND STAR ANSWERS, EACH FROM A DIFFERENT MOMENT OF THE STORY NEW

DIVE DEEP · AIQB Q1 **Q1. "Tell me about a time when you were trying to understand a complex problem on your team and you had to dig into the details to figure it out."**

I stopped reading oversell reports and started reading event traces — one SKU, one day, every event, every bucket. The pattern was never "the system is wrong"; it was an event landing in zero buckets or two. Take the worked SKU: 560 available. A store rings three units. If the event hits no bucket, AFS stays 560 and we promise three units that are gone. If it hits two — sold and shipped-not-billed both decrement — AFS goes to 554 and we hide three. Same event, three possible answers, one right: 557. So I wrote one rule — every event maps to exactly one bucket, a reversal must reference its original, a replay is a no-op — and turned it into before/after assertions per cell. Then I read the issues log against it: 836 rows, 441 Blocker or Critical. The defects were not random; they clustered where two systems used different grain. The result: zero customer-facing incidents through both go-lives, and a rule the control owners could keep using after I left.

Number to land: 557 — not 560, not 554 · **Pivot to NACF:** At NACF the same trace is unload → scan → stow → sellable; I would pull one ASIN's inbound event trace and look for events that land in zero or two states. · **Do NOT say:** that I wrote the code or personally found the bugs; that the matrix alone kept incidents at zero.

INVENT AND SIMPLIFY · AIQB Q1 **Q2. "Give me an example of a complex problem you solved with a simple solution."**

About a dozen impacted systems, about thirty build tracks — and I refused to write thirty test plans. I wrote one asset: a matrix of physical events against node-and-channel cells, each with a before and after assertion, and one entry rule — no story enters QA without a cell reference. Epics were per module — reserve module, AFS engine, SNB, control screens — slotted by business criticality × effort, so every track mapped onto the same cells. That turned "is it ready?" from an argument into a count: Blocker plus Critical open equals zero, and every live cell green. When my first in-transit rule turned out wrong, the matrix absorbed the fix as four new rows, not a new project. The same logic made a new node or channel a matrix row. The result was zero customer-facing incidents through both go-lives with 85.4% of 836 logged issues closed.

Number to land: one rule · one asset · one gate (cell reference to enter QA) · **Pivot to NACF:** NACF launches many parallel tracks — a new vendor cohort, a new IXD lane; one event × node matrix gives a countable ready-to-launch gate. · **Do NOT say:** the 61-cell count as fact; that I built the tooling.

INSIST ON THE HIGHEST STANDARDS · AIQB Q2 **Q3. "Tell me about a time when you were unsatisfied with the status quo. What did you do to change it?"**

I changed what "tested" meant: not 'we ran the flow' but 'every live cell asserted, with numbers, before and after.' Each cell carried an expected state — AFS 560 to 557, SNB 40 to 43, drift zero — so a pass was a number, not an opinion. Then I put the standard in rooms, not memos: three dated end-to-end days — Inbound 11/22, Dotcom 12/20, Retail 1/30 — with every function in one room, every finding logged with a severity and an owner before anyone left. The go/no-go bar was written in advance: Blocker plus Critical open equals zero, mock three inside the 0.5% tolerance, runbook rehearsed, rollback armed. I said I would have called no-go on one open Blocker — and I never had to. The result: zero customer-facing incidents, and a gate QA, not I, defended.

Number to land: three dated E2E days; Blocker + Critical open = 0 · **Pivot to NACF:** Before any NACF launch I would publish the same bar — what the gate asserts, in numbers, and who may fail it. · **Do NOT say:** that I never faced pressure; that the bar was only mine — QA owned the gate.

EARN TRUST · AIQB Q5 **Q4. "Tell me about a time when your team's goals were out of alignment with another team you relied on in order to meet your goal."**

DC Ops did not trust a systems program to respect the floor, so I made sure nothing reached them as a surprise. During build, QA demoed each matrix family — receipts, transfers, pick and pack reserves, ship confirms — to DC Ops and the planners. By the time UAT started, their sign-off was confirmation, not discovery. QA owned the gate and could fail a build, and DC Ops saw that it could. I also kept the floor's reality inside the design: the January planning go-live (purchasing and inbound, reserve rules live against demand) left the floor untouched, and warehouse execution moved only in May. The result was go-lives where DC Ops owned the robotics gate and the dial and the floor ran on them, with zero customer-facing incidents.

Number to land: January reserve rules first; May execution second; zero incidents · **Pivot to NACF:** At NACF I would demo each inbound event family to the building before the first live trailer — the same 'confirmation, not discovery' rule. · **Do NOT say:** that I ran the floor; DC Ops did.

SAME STORY, THREE ANGLES — DATA · CONFLICT/INFLUENCE/BACKBONE · FAILURE-LEARNING NEW

DATA ANGLE · DIVE DEEP

"Start with the log: 836 rows, 441 of them Blocker or Critical — 52.8%."

Headline metric: 441 / 836 = 52.8% high-severity; 714 closed = 85.4%

Cut the log by severity, owner and seam; the matrix made coverage countable. What it revealed: 62.6% of the rows sit in the three flows where an event crosses systems (Outbound 238, Retail 172, Inbound 113 = 523, computed from the file), which is where the matrix cells concentrate. Honest limit: rows were not tagged by cell.

CONFLICT / INFLUENCE ANGLE · EARN TRUST

"I owned a test asset for ~30 build tracks in other orgs and none of them reported to me."

Headline metric: ~30 build tracks · one entry gate

The gate (no story enters QA without a cell reference) moved every track onto one asset; QA owned it and could fail a build; DC Ops confirmed because QA had already demoed to them. Influence came from a countable rule, not rank.

FAILURE / LEARNING ANGLE · ARE RIGHT, A LOT

"My own first in-transit rule passed every cell I wrote — and it was wrong."

Headline metric: $\sigma \approx 0.3$ d → window ≈ 0.49 d ≈ 95%; 4 cells added

"Never promise in-transit" starved dotcom of fast movers one day from the building; the matrix asserted my rule, not whether the rule was right. Now: both sides of a rule get a number, back-test against history first. (Record: master S4.)

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS, WITH NUMERIC ANSWERS NEW

How do you know it was the matrix and not the E2E days or the team?

You cannot, and I would not claim it. Record: zero customer-facing incidents, 441 Blocker/Critical rows dispositioned, B+C open = 0 at go/no-go. The measurable yield is the share of the 441 first detected by a cell assertion — the log was not tagged by cell, so I cannot produce it.

Say: *"I can't isolate the matrix from the E2E days; the number that would change my mind is a customer-facing incident traced to an event with no cell."*

Why is a 61-cell matrix not over-engineering against an 836-row log?

The log is the detector; the matrix is the coverage map. At 4 h a cell, 61 cells is 244 h ≈ $26.8K (modeled); one escaped cell-class is ≈$14.8K/yr on illustrative inputs — break-even ≈1.8 cell-classes.

Say: *"The log tells me what broke; the matrix tells me what I never tried — and it costs less than two escaped cell-classes."*

What did the matrix not catch, and what changed?

The v1 in-transit rule: cells asserted my rule and it was wrong; the fix added four cells and a back-test-before-publish requirement (σ ≈ 0.3 d, window ≈ 0.49 d ≈ 95%).

Say: *"A matrix checks that the system does what the rule says; only history tells you whether the rule is right — so now both sides of a rule get a number first."*

20-SECOND VERSION + NACF BRIDGE NEW

20-second version. At the Utah DC I made "tested" countable: every physical event had to land in exactly one inventory bucket, each cell asserted before and after, and no story entered QA without a cell reference — zero customer-facing incidents through both go-lives, with 441 of 836 logged issues Blocker or Critical and none reaching a customer.

NACF bridge. NACF inbound has the same seam — a trailer unloaded, a pallet received, a unit stowed, a unit sellable. The booklet's "stranded" inventory is exactly an event that landed in zero states. I would build the same event × node matrix for receive → stow → sellable so every dock event lands in exactly one inventory state before a new FC ramps.

U2 — The profile before the design — SKU overlap, order shape and demand variability per node across both books (MCS and S/4): the discovery that sized the one-pool case and bounded its $2.2M NEW

LPs this story serves here: Dive Deep (primary — both books at SKU × node grain) · Are Right, A Lot (a bounded claim with a kill number) · Learn and Be Curious (backup — the pooling math and the retail/dotcom order shapes) · Think Big (backup — two pools to one)

Process family: Plan / Source — inventory positioning and pooling analysis; the discovery profile that sized the case for one comingle pool

Honesty label. Record: Discovery (3/29 → 4/30) profiled both books — MCS and S/4 — and the 801/901 nodes for SKU overlap and order profiles per node, with node-by-node sessions across ~15 functions; the design argument started from their data. The √2 pooling release, the $50M average inventory × 25% safety stock × 60% overlap and the ≈$1.6M/yr are S2's **modeled** numbers on an illustrative 100K-units/week DC. **Not in the record:** the profile's actual outputs — measured overlap, σ ratio, correlation, order-shape cuts. Every range below is toolkit math on labeled inputs. Never say the profile "measured" a release; say it bounded one.

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH

Dive Deep. I profiled both books at SKU × node grain before any design argument, so the debate started from their own data instead of opinions about it.

Are Right, A Lot. I refused to carry the textbook $2.2M as a point: I showed what would shrink it (unequal pools, correlation), bounded it at ≈$0.74M–$2.20M, and named the measurement that settles it.

Learn and Be Curious. I worked the variance-pooling formulas by hand on small numbers and learned the retail-vs-dotcom order shapes in the node sessions, so I could ask the right three questions of the data.

Think Big. The recommendation was structural — two pools to one, with three planning identities — and it stood even when the pooling dollars shrank, because the case never rested on them alone.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. Before anyone argued design at Sephora's Utah DC, there were two inventory books — MCS and S/4 — and two systemic warehouses in one building, Dotcom 801 and Retail 901, and a business case that said "pool them." Whether pooling was worth it turned on three things nobody had put side by side: how many SKUs both pools carried, whether the two nodes' orders looked alike, and how variable and how correlated the demand was. **Task.** Own the discovery profile that the location and inventory model would stand on — about a dozen impacted systems, 60+ stakeholders, none reporting to me. **Action.** Discovery ran 3/29 to 4/30: both books profiled for SKU overlap and order profiles per node, node-by-node sessions across about fifteen functions. I turned the profile into three tests — overlap, order shape, variability — and a bounded claim: textbook √2 pooling on $7.5M of duplicated poolable safety stock is a $2.2M ceiling; unequal or correlated pools cut it to roughly $0.7M to $2.2M, and about 87% of the $1.6M a year modeled benefit does not depend on pooling at all. That fed the decision — one physical pool, three planning identities. **Result.** Primary metric: the one-time pooling claim moved from a single textbook number to a bounded range, about $0.7M to $2.2M, modeled, with discovery closed on 4/30. The +15% and the zero incidents are S2's record; the profile outputs are illustrative and I would not quote them as measured.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — Two systemic warehouses in one building transferring stock to itself, two books (MCS and S/4), a case for one comingle pool resting on three unmeasured assumptions: that both pools carry the same SKUs, that their orders look alike enough to share a pick face, and that pooling their demand variability would release stock. A pooling claim built on a textbook assumption is the first number a skeptic pulls on.

T — Produce the profile the design could stand on and a claim that survives the first pull: which SKUs overlap, what each node's order looks like, how much of the $2.2M survives unequal and correlated pools — and which measurement turns the model into a record. None of the systems or analysts reported to me; ~15 functions sat in the sessions.

Baselines on the table: planning pools 2 · average inventory $50M (illustrative) × 25% safety stock × 60% held in SKUs both pools carry = $7.5M duplicated poolable stock · self-transfers ≈260,000 units/yr ≈5.0% of an illustrative 5.2M units/yr · efficiency index 100.

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery (3/29 → 4/30)** — pulled both books at SKU × node grain; cut for overlap (which SKUs live in both 801 and 901), order shape per node (retail store-replenishment style vs dotcom small-order style), and demand variability per SKU; ran node-by-node sessions with ~15 functions; wrote the bucket inventory. *Exit bar:* sessions closed 4/30; every bucket owned by one system; open questions carried with owner and date.

- **Plan & Design (5/15 → 8/14)** — turned the profile into the three-identity design (one physical location, three planning lenses) and into a bounded pooling claim in the sponsor pack: ceiling $2.2M, plausible floor ≈$0.74M, recurring benefit mostly independent of pooling. *Exit bar:* council sign-off 7/31 and FSD 8/14 with the range, not a point, in the case.
- **Build & Test (Aug → Jan/Apr)** — carried the profile's cuts into the matrix rows (U1) and the interim shadow monitor; the node/channel/order-shape cuts became test families. *Exit bar:* matrix families trace to a profile cut; E2E days 11/22 · 12/20 · 1/30.
- **Cutover & Go-Live (January; May 1 → Jul 1)** — no new analysis on the critical path — the profile's job was done at design; it re-entered only as the reference for the "which book does this report read" declaration during the interim. *Exit bar:* every report declared its system of record for the interim.
- **Hypercare / Close (Jun → Jul)** — the record's own firming measurement — SKU-level on-hand on the last day of 801 against the first stable month of 901 — is the way the release becomes a record; flagged as the open measurement. *Exit bar:* pooling stays labeled "modeled" until that comparison is run.

Influence and ownership. Mine: the profile design, the three tests, the bounded claim, the design recommendation. Others': the extracts (platform/data teams), the node sessions (DC Ops, Planning, Digital, Finance), the sign-off (steering). Digital's worry that a virtual Retail DC would blur their forecasting lens was answered by the design — three planning identities over one physical location — not by an argument.

> **Designed the process; others own it now.** The profile cuts (overlap · order shape · variability) are the template the next DC's discovery reused; the three-identity design is the standing location model. **Trade-off put to leadership:** a precise-looking $2.2M versus an honest range — I took the range, because the first number a skeptic pulls on is the one resting on an assumption.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY

- **$** — pooling release (one-time, modeled): textbook ceiling $7.5M × 29.3% = ≈$2.2M; plausible floor ≈$0.74M at σ ratio 1/3 and ρ = 0.5. Recurring ≈$1.43M (87% of ≈$1.65M) does not depend on pooling. All modeled on S2's illustrative DC — never signed.
- **#** — 2 books profiled · 2 planning pools → 1 · 3 planning identities · self-transfers ≈260,000 units/yr (≈5.0% of illustrative volume) → 0 by construction (record design).
- **%** — release range 9.9%–29.3% of poolable stock; overlap sensitivity 40/60/80% → $1.46M / $2.20M / $2.93M (modeled).
- **Time** — sessions closed 4/30 (record); the profile preceded council 5/15 → sign-off 7/31 → FSD 8/14.
- **Customer** — zero customer-facing incidents through both go-lives (S2 record) — the constraint the one-pool design had to live inside.
- **Quality** — every pooling dollar carries its input and basis label; the claim names the measurement that would firm it.

L6 LEVEL EVIDENCE — every line is this story's record or labeled model, no new canon numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	A case for pooling resting on assumptions nobody had measured. I defined the three tests and what each would change.
Scope & influence	~15 functions in node sessions; extracts from data teams; steering signed the criteria. I influenced by putting their numbers on one page.
Execution trade-off + mechanism others own	Point estimate versus honest range — chose the range. Mechanism others own: the three-test profile and the bounded-claim format in the sponsor pack.
Impact	A one-pool design whose recommendation survived a ≈$1.5M-smaller worst case on the one-time number.
Process improvement	Discovery ends with a profile (overlap · shape · variability) and a measurement that converts the model to a record — reused by the next DC.
Complexity & consensus	Retail and dotcom order shapes, two books and three planning lenses reconciled into one location model.
Root cause at scale	The fragile part of the case was an assumption (equal, independent pools), not a number; bounding it removed the single point of failure.

PROBING — FIVE FACETS, THEN THE HARDEST FOLLOW-UPS NEW

THE FIVE FACETS — WHERE EACH ONE LIVES IN THIS STORY

1 · Data analysis. Grain: SKU × node (801 / 901 / stores) in both books. Joins: MCS ↔ S/4 on SKU; overlap flag by node pair; demand history per SKU per node. Cuts: overlap by value; order shape per node (lines per order, units per line — illustrative until pulled); σ and correlation per overlapping SKU. Revealed (modeled): the case is most sensitive to correlation and σ ratio, and least to overlap, once the textbook is replaced by the range.

2 · Solution design. Options: (A) keep two pools and reconcile (status quo); (B) pool physically but plan as one blended identity; (C) one physical pool, three planning identities. Chose C — A keeps self-transfers; B blurs the forecasting lens Digital needed. Why: the profile showed the case did not need the safety-stock row to be big.

3 · Math & data logic. Equal independent pools: release = $1 - 1/\sqrt{n} = 1 - 1/\sqrt{2} = 29.3\%$. Unequal: $1 - \sqrt{(\sigma_1^2+\sigma_2^2)}/(\sigma_1+\sigma_2)$. Correlated: $1 - \sqrt{(\sigma_1^2+\sigma_2^2+2\rho\sigma_1\sigma_2)}/(\sigma_1+\sigma_2)$. Dollars = poolable stock × release; carry = release × 10%. Break-even sentence: the claim fails only if the recurring rows fail.

4 · Implementation. Discovery 3/29 → 4/30; design to FSD 8/14; the profile cuts carried into matrix rows; the SKU-level on-hand comparison (last day 801 vs first stable month 901) is the firming measurement. Owners: me (profile and claim), data teams (extracts), Finance (inventory

valuation).

5 · Probe questions. Below: why not trust √2, how you know the 60%, what if overlap is 20%, did the profile change the design, and the three trap drills.

FACET 5 — PROBE QUESTIONS (CHALLENGE Q&A TUNED TO THIS INTERVIEWER)

Infra — why not just trust √2?

Because it assumes two equal, independent pools on the same SKUs — three assumptions at once. I showed the release at σ ratio 1, 1/2, 1/3 and 1/4 (29.3%, 25.5%, 20.9%, 17.5%) and at correlation 0.3 and 0.5 (19.4%, 13.4%); jointly pessimistic it is 9.9%. The textbook is the ceiling, not the base.

Infra — how do you know the overlap is 60%?

I don't — it is S2's illustrative input, the share of poolable stock in SKUs both pools carry. The profile is what measures it; at 20% overlap the equal-pool release is $0.73M, at 80% $2.93M. The case never depended on getting that one right.

Infra — if the release is that uncertain, why pool at all?

Because the pooling carry is only 13% of the modeled recurring benefit. Labor at +15% (≈$0.88M, record efficiency), split shipments (≈$0.45M) and self-transfer handling (≈$0.10M) are $1.43M; self-transfers alone were ≈260,000 units a year of movement that created no value.

Infra — did the profile change the design?

It shaped it: it is why I kept three planning identities over one physical location rather than one blended lens, and why the matrix has rows per node type and order shape. I would not claim it changed the decision to pool; that case was already strong on the recurring rows.

Infra — what would you pull first at a new node?

SKU-level on-hand and sales for the two pools, joined by SKU: overlap by value, σ and correlation per SKU, then order shape — lines per order and units per line. Three pulls, one afternoon, and the claim has inputs.

BUSINESS IMPACT MODEL — KPI DRIVERS, BASELINE → AFTER

DRIVER	BASELINE	AFTER	$ / EFFECT	BASIS
Planning pools	2	1 (three planning identities)	self-transfers → 0	record design
Pooling claim (one-time)	≈$2.2M point	≈$0.74M–$2.20M range	carry ≈$0.07M–$0.22M/yr	modeled (toolkit label)
Benefit independent of pooling	not separated	≈$1.43M/yr (87%)	labor + splits + self-transfer	modeled; +15% is record
Overlap sensitivity (equal pools)	—	40/60/80% → $1.46M / $2.20M / $2.93M	—	modeled
Measurement to firm the release	none	last-day 801 vs first-month 901 SKU on-hand	turns model into record	record proposal

THE MATH — FOUR-TABLE DERIVATION (FORMULA → SUBSTITUTION → RESULT) NEW

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Warehouses / pools	`planning pools = 2 (801 and 900/901 identities)`	record	2
2	Duplicated safety stock	`$50M × 25% = $12.5M; × 60% = $7.5M`	average inventory, SS share and overlap share are S2's illustrative inputs (modeled)	$7.5M poolable
3	Self-transfer burden	`260,000 / (100,000 × 52) = 260,000 / 5,200,000 = 5.0%`	260K units/yr modeled; 100K units/wk illustrative	5.0% of volume is non-work
4	Textbook release	`1 − 1/√2 = 1 − 0.707 = 29.3%`	equal, independent pools (toolkit label)	29.3%
5	What the textbook never saw	`σ ratio r = σ₂/σ₁ and correlation ρ unmeasured`	VERIFY — profile outputs not in the record	release could be lower

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Test 1 — overlap	`poolable = $12.5M × overlap → 40%: $5.0M · 60%: $7.5M · 80%: $10.0M`	overlap is a measured input at a new node	$5.0M / $7.5M / $10.0M
2	Test 2 — σ ratio	`f(r) = 1 − √(1+r²)/(1+r): r=1 → 29.3% · r=½ → 25.5% · r=⅓ → 20.9% · r=¼ → 17.5%`	unequal independent pools (toolkit label)	17.5%–29.3%
3	Test 3 — correlation (equal pools)	`f(ρ) = 1 − √((1+ρ)/2): ρ=0.3 → 1 − √0.65 = 19.4% · ρ=0.5 → 1 − √0.75 = 13.4%`	equal σ; correlation reduces release	13.4%–19.4%

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
4	Jointly pessimistic	`r = ⅓, ρ = 0.5: 1 − √(1 + 1/9 + 2×0.5×⅓)/(4/3) = 1 − √1.4444/1.3333 = 1 − 1.2019/1.3333 = 9.9%`	illustrative corner of the range	9.9%
5	Dollar range	`$7.5M × 9.9% = $0.74M · $7.5M × 29.3% = $2.20M`	poolable stock × release	≈$0.74M–$2.20M
6	Firming measurement	`last-day 801 SKU on-hand vs first stable month of 901 → release = the difference`	the record's own proposal (not yet run — VERIFY)	model → record

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Planning pools	2	1	record design
2	One-time pooling claim	$2.2M point (textbook)	$0.74M–$2.20M range	modeled
3	Recurring benefit independent of pooling	not separated	$1.43M of $1.65M = 86.7%	modeled
4	Self-transfers	≈260,000 units/yr	0 by construction	record design
5	Headline total (recurring)	≈$1.65M	≈$1.50M–$1.65M	modeled

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Labor at +15%	`31,300 h × $28 = $876,400`	hours from S2 (record +15%); $28 loaded (modeled)	≈$0.88M/yr
2	Split shipments	`45,000 × $10 = $450,000`	S2 softest row (modeled)	≈$0.45M/yr
3	Self-transfer handling	`260,000 × $0.80 × 50% = $104,000`	the other half already sits in labor (modeled)	≈$0.10M/yr
4	Recurring without pooling	`876,400 + 450,000 + 104,000 = $1,430,400`	rows 1–3	≈$1.43M/yr
5	Carry on the release	`$2.2M × 10% = $220,000 · $0.74M × 10% = $73,959`	10% cost of capital (benchmark 8–12%)	≈$0.22M / ≈$0.07M
6	Headline range	`1,430,400 + 220,000 = $1,650,400 · 1,430,400 + 73,959 = $1,504,359`	rows 4–5	≈$1.65M / ≈$1.50M

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Overlap share (equal pools)	40% → $1.46M	60% → $2.20M	80% → $2.93M
σ ratio r (ρ = 0)	⅓ → $1.57M	½ → $1.91M	1 → $2.20M
Correlation ρ (r = 1)	0.5 → $1.00M	0.3 → $1.45M	0 → $2.20M
Cost of capital on $2.2M	8% → $0.18M	10% → $0.22M	12% → $0.26M
Headline recurring total	≈$1.50M (floor release)	≈$1.65M (ceiling release)	pooling row ≤ 13% of total

SPOKEN STATEMENT

> "The profile did two things. It told me which SKUs, which node shapes and how much variability the case rested on, and it kept me from carrying a textbook number as a fact. The pooling release is about $2.2 million at the ceiling — equal, independent pools — and about three-quarters of a million at a pessimistic corner; I show the range. What does not move is that about 87% of the modeled benefit is labor at the signed +15%, split shipments and self-transfers, none of which depend on pooling. The thing that turns the model into a record is one comparison: SKU-level on-hand the last day of 801 against the first stable month of 901."

IF CHALLENGED

"So the $2.2M in S2 is wrong?"

It is the ceiling on S2's stated inputs, and S2 labels it modeled and textbook. This story is the bounding of it — what survives if the pools are unequal or correlated — not a retraction.

"You never ran the comparison?"

I would not claim it. The comparison is the measurement the record proposes; until it is run the number stays labeled modeled. If you ask me whether pooling released that stock, my answer is: here is the range and here is the one-afternoon pull that settles it.

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Tell me about a time you used data to challenge an assumption.	Dive Deep	Both books at SKU × node grain; the equal-independent-pools assumption bounded at 9.9%–29.3%.	Never say the profile "measured" the release.
Tell me about a decision you made with incomplete data.	Are Right, A Lot	A bounded claim with a named measurement; recommendation stable across the whole range.	Do not present the 60% overlap as measured.
Tell me about learning something outside your area.	Learn and Be Curious	Variance pooling and the order shapes at retail vs dotcom nodes.	Skip the BlueYonder/Locus internals.
How do you decide whether to consolidate nodes in a network?	Functional — network design	Overlap, order shape, variability/correlation; recurring rows first, safety stock last.	Never quote $2.2M as a record.

BEHAVIORAL PACK — FOUR SEPARATE 90-SECOND STAR ANSWERS, EACH FROM A DIFFERENT MOMENT OF THE STORY NEW

DIVE DEEP · AIQB Q3 **Q1. "Tell me about a problem you had to solve that required in-depth thought and analysis."**

The accepted assumption was that two pools become one and safety stock drops by 29%. That is the square-root pooling result, and it assumes the two pools are equal and independent — which retail and dotcom demand for the same SKU almost certainly are not. So in discovery I stopped quoting the textbook and asked the data three questions: which SKUs do both pools carry, how big is each pool's variability relative to the other, and how correlated are they? I put the answer as a range instead of a point. Equal and independent gives 29.3%. If one pool is a third the size of the other, 20.9%. If correlation is 0.5, 13.4%. Jointly pessimistic, 9.9%. On $7.5 million of duplicated poolable stock that is $0.74 million to $2.2 million. Then I checked whether the case still stood: about 87% of the modeled benefit — labor at the signed +15%, split shipments, self-transfers — does not depend on pooling at all. The design stood; the claim became honest.

Number to land: 9.9%–29.3% → ≈$0.74M–$2.2M; 87% independent of pooling · **Pivot to NACF:** At NACF the same three pulls decide whether two FCs' buffers belong together — same ASINs, same demand shape, correlation — before I claim any release. · **Do NOT say:** that the profile measured the release; that $2.2M is a record.

ARE RIGHT, A LOT · AIQB Q1 **Q2. "Tell me about a time when you didn't have enough data to make the right decision."**

I made the recommendation robust to the thing I did not know. I did not have measured σ or correlation for the overlapping SKUs when the sponsor pack was written. So I built the claim as a range with a kill number: the only way the one-pool recommendation fails is if the recurring rows fail, and those rest on a signed +15% efficiency, a split-shipment row I flagged as the softest, and the self-transfer move that disappears by construction. Then I named the measurement that converts model to record — SKU-level on-hand on the last day of 801 against the first stable month of 901 — and I told steering what number would change my mind: if split shipments didn't move, the total drops to about $1.1 million and I would say so. The recommendation was the same across the whole range, which is the test of a decision made with incomplete data.

Number to land: recommendation stable from $1.50M to $1.65M recurring · **Pivot to NACF:** At NACF placement decisions are made on incomplete data constantly; the habit I would bring is a range, a kill number and the one measurement that firms it. · **Do NOT say:** that I knew the overlap; that the model was validated.

LEARN AND BE CURIOUS · AIQB Q1 **Q3. "Tell me about a time when you realized you needed a deeper level of subject matter expertise to do your job well."**

I started by asking what the word "pooling" actually assumes. The business case said "pooling," and I wanted to know exactly what that word assumed. So I worked the variance-pooling toolkit — equal independent pools, unequal pools, correlation — and checked each formula by hand on small numbers until I could do it on a whiteboard. Then I learned the shapes of the two nodes' orders: retail store-replenishment style versus dotcom single-customer orders, because that is what decides whether two pools can share a pick face. I sat in the node sessions with about fifteen functions asking what a normal day looked like. By the end of discovery I could explain, in one page, why the pooling number was a ceiling and what each node's order looked like. Zero customer-facing incidents later is not mine alone, but the design started from a profile I could defend.

Number to land: three formulas hand-checked; ~15 functions in node sessions · **Pivot to NACF:** NACF placement is the same toolkit — I would arrive having learned the ASIN-level demand shapes before proposing a buffer. · **Do NOT say:** that I invented the pooling math; it is the toolkit's, and I label it.

THINK BIG · AIQB Q1 **Q4. "Tell me about time when you were working on an initiative or goal and saw an opportunity to do something much bigger or better than the initial focus."**

The ask was to merge two warehouses' reporting; the bigger structure was one physical pool. Two systemic warehouses sat in one building and moved stock to each other — about 260,000 units a year on paper, roughly 5% of volume that created no value. I proposed collapsing them into one pool with three planning identities so each channel kept its forecasting lens without a second truth. Digital worried a virtual retail DC would blur their lens; I made the concern the design — the three identities — rather than arguing. The bigger structure was riskier, so I staged it: two go-lives, each carrying one defect class. And I made sure the case did not hang on the most uncertain number: even at the pessimistic pooling corner, the recurring benefit is about $1.5 million. Big, but with the downside bounded.

Number to land: ≈260K units/yr self-transfers → 0; 2 pools → 1 · **Pivot to NACF:** At NACF a bigger structure — fewer buffers pooled upstream — needs the same discipline: bounded downside before ambition. · **Do NOT say:** that pooling alone paid for it; that the dollars are signed.

SAME STORY, THREE ANGLES — DATA · CONFLICT/INFLUENCE/BACKBONE · FAILURE-LEARNING NEW

DATA ANGLE · DIVE DEEP

"The textbook says 29%. Here is what survives when the pools are unequal and correlated."

Headline metric: 9.9%–29.3% release; $0.74M–$2.20M

Three tests (overlap, σ ratio, correlation) turned one number into a surface; the case's dependence on pooling is ≤13%. Honest limit: the inputs are illustrative until the profile is pulled.

CONFLICT / INFLUENCE ANGLE · EARN TRUST

"Digital worried a virtual Retail DC would blur their forecasting lens — the profile gave me a way to say yes to them."

Headline metric: 3 planning identities over 1 physical location

The concern became the design: each channel kept its lens; no second truth. No one had to lose an argument. Steering signed the criteria; DC Ops and Planning confirmed the node sessions.

FAILURE / LEARNING ANGLE · ARE RIGHT, A LOT

"In S2 I say $2.2M one-time — that is the equal-pools ceiling, and I should lead with the range."

Headline metric: $2.2M point → $0.74M–$2.20M range

I label it modeled and textbook, but a point invites the first pull and the first pull finds the equal-independent assumption. Do differently: say the range first, name the kill number, and never let the ceiling stand alone.

confirm whether the sponsor pack carried the poi

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS, WITH NUMERIC ANSWERS NEW

What number would have changed your mind about pooling?

If the recurring rows failed: the split-shipment row (≈$0.45M, softest) not moving drops the total to ≈$1.1M; if the +15% were not signed the case would be different. Pooling's carry is only $0.07M–$0.22M/yr, so no outcome of the pooling math alone could flip it.

Say: *"The pooling row is at most 13% of the benefit, so the number that would change my mind is split shipments or the signed efficiency — not the safety-stock release."*

Isn't the 60% overlap just made up?

It is S2's illustrative input — said so. At 20% overlap the equal-pool release is $0.73M; at 80% it is $2.93M. The profile's job is to replace it with the measured value, join by SKU, value-weighted.

Say: *"It is an illustrative input I label as such; here is the one-afternoon pull that replaces it, and here is what the answer does to the claim across 20% to 80%."*

How do you know it was pooling and not seasonality that moved stock?

I can't — and I don't claim it. The record has +15% efficiency measured by DC Ops post-stabilization and zero incidents; the pooling release is modeled. The firming comparison is last-day 801 versus first stable month of 901 on SKU-level on-hand, seasonally matched.

Say: *"The pooling dollars are modeled; if you want it as a record, it is a seasonally-matched SKU-level on-hand comparison — that is the one measurement I would run."*

20-SECOND VERSION + NACF BRIDGE NEW

20-second version. Before the design argument at Sephora's Utah DC I profiled both inventory books for SKU overlap and order shape per node and turned the textbook pooling number — $2.2M — into a bounded range of about $0.74M to $2.2M, with about 87% of the modeled benefit not depending on pooling at all; that range, not a point, went into the sponsor pack.

NACF bridge. NACF's placement and buffer questions start with the same three pulls — do two FCs carry the same ASINs, do they see the same demand shape, how correlated are they — because pooling variability upstream only pays where correlation is low, and an INV-D transfer is how the pooled unit actually moves. I would bring the range-and-kill-number habit to any buffer-positioning claim.

U3 — Merch reserve — visible, never promisable: pricing the no (and the asymmetry behind it) so one comingled pool never sells stock the floor cannot pick NEW

LPs this story serves here: Have Backbone; Disagree and Commit (primary — the priced no) · Customer Obsession (oversell is a customer defect) · Earn Trust (visibility offered, the no written as a row) · Success and Scale Bring Broad Responsibility (a customer harm, not a ledger error)
Process family: Plan / Deliver — comingled-inventory allocation at a shared node: which stock is promisable to which channel, and which is physically present but not for sale

Honesty label. Record: Merch Reserve and Lost/Found sit outside S4_Avail, so there is no double-subtract path; Merchandising wanted merch reserve promisable; I priced it (unpickable stock sold) and offered visibility without promisability; the no went into the FSD as a row, not a meeting minute; the asymmetry (oversell is a customer defect, undersell a planning variance) is the policy; comingle-reserve improvements were held out of the release to protect zero incidents and priced as a later enhancement at steering; zero customer-facing oversell incidents through both go-lives. **Illustrative:** the 20% release rate, the 10,000-unit reserve, the 50-unit worked SKU and the retail/dotcom pool split. The margin $19 and the $6 + $4 + $1 + $19 = $30 incident cost are S1's benchmark. I do not know how Merchandising defined or sized the reserve. I owned the definition and the no; Merchandising owned the reserve.

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH

Have Backbone; Disagree and Commit. Merchandising wanted merch reserve promisable; I priced it, said no, and wrote the no into the FSD as a row so it survived the room.

Customer Obsession. I treated oversell as a customer defect and undersell as a planning variance — and accepted visible undersell to make oversell zero by construction.

Earn Trust. I gave Merchandising what they actually needed — visibility of the reserve — so the no cost them a lever, not their standing.

Success and Scale Bring Broad Responsibility. A promise on stock the floor cannot pick is a customer harm at scale; the price in dollars was the floor of the argument, not the whole of it.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. At Sephora's Utah DC one physical pool had to serve two channels, and Merchandising held some of that stock back as reserve. Merchandising wanted the reserve promisable — it was in the building, so why not sell it. **Task.** I owned the definition of "available" across Store, Retail DC and Dotcom DC, and I owned no system. **Action.** Discovery: a bucket inventory where every bucket had one owning system; merch reserve and lost/found sat outside the supply the AFS engine computes from, so there was no double-subtract path. Plan & Design: I priced the ask — stock the floor may not pick, sold — as a break-even: promise it only if more than roughly 37 of every 100 reserved units would actually be released, and on a 20% release rate that is about −$50,000 per 10,000 units, or about −$200,000 on the all-in cost. Then I offered what Merchandising actually needed: visibility without promisability. The no went into the FSD as a row, signed by Strategy, Inventory Management and Inventory Accounting. Comingle-reserve improvements were held out of the release to protect zero incidents and priced as a later enhancement. **Result.** Primary metric: customer-facing oversell incidents — recurring across three node types → zero through both go-lives, with zero units of merch reserve in published AFS. The dollars are a what-if on labeled inputs; the zero is the record.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — One physical pool, two channels, three planning identities — and stock physically in the building that was not for sale: Merchandising's reserve, lost-and-found. Merchandising wanted the reserve promisable; Finance wanted on-hand to tie to the book; dotcom wanted in-transit promisable. Most oversell bugs are vocabulary bugs, and "available" had three meanings.

T — Define, per node and per channel, which buckets are subtracted from supply and which sit outside it — and say no to the one request that would have turned unpickable stock into a promise. I owned no system; the signatories were Supply Chain Strategy, Inventory Management and FSC Inventory Accounting.

Baselines on the table: working definitions of "available" 3 · customer-facing oversell incidents recurring across three node types, target zero · worked SKU: Basis 980, buckets 420, AFS 560 · merch reserve and lost/found outside S4_Avail.

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery (3/29 → 4/30)** — bucket inventory with one proposed owning system per bucket; node-by-node sessions; Merchandising's need written down as a need — see the reserve — not as a mechanism. *Exit bar:* every bucket owned by exactly one system; sessions closed 4/30.
- **Plan & Design (5/15 → 8/14)** — kept merch reserve and lost/found outside S4_Avail; wrote the lower-of-two basis and the AFS equation; priced the promisable-reserve ask as a break-even; offered visibility without promisability; held the asymmetry. *Exit bar:* FSD signed 8/14;

the no is a row; every bucket owned by exactly one system.

- **Build & Test (Aug → Jan/Apr)** — matrix cells that assert the reserve never appears in published AFS (U1) and a visibility view for Merchandising; held the comingle-reserve improvements out of the release. *Exit bar:* Blocker + Critical open = 0; reserve-copy invariants checked per SKU.
- **Cutover & Go-Live (January; May 1 → Jul 1)** — reserve rules live against demand at the January planning go-live with the floor untouched; execution moved in May; no SKU with two published AFS values. *Exit bar:* oversell incidents zero through both go-lives.
- **Hypercare / Close (Jun → Jul)** — daily ISM-vs-MB52 drift; Negative AFS and AFS Correction under control owners (U6); the improvement list handed to steering as a priced later enhancement. *Exit bar:* drift 0 on consecutive days; enhancement priced, not promised.

Influence and ownership. Mine: the bucket inventory, the break-even, the asymmetry, the offer of visibility, the row in the FSD. Merchandising owned the reserve; control owners own the screens. Digital's forecasting-lens concern was answered by the three-identity design, not by a ruling.

> **Designed the process; others own it now.** The reserve rule is now a row in the FSD and a cell family in the matrix; Merchandising sees the reserve and Inventory Control chases variance on the screens. **Trade-off put to leadership:** sell the reserve and accept unpickable-stock cancellations, or hold it back and accept visible undersell — I priced both and recommended undersell.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY

- **$** — no record dollar for this decision. What-if (modeled, **illustrative**): at a 20% release rate, promising 10,000 reserved units costs −$50,000 (incremental cancellation cost) to −$202,000 (S1's all-in $30 per incident) against the ≈$38,000 of expected sales; break-even release 36.7% (61.2% all-in). Not claimed as a saving.
- **#** — 3 working definitions → 1 signed AFS; 0 units of merch reserve in published AFS (record design); 3 organizations signed the row.
- **%** — break-even release rate p* = 36.7% (modeled); oversell rate behind S1's ≈$0.9M row is 0.10% of orders (benchmark 0.05–0.25%; the record is incidents → zero).
- **Time** — FSD signed 8/14; January reserve go-live; May execution go-live (record).
- **Customer** — customer-facing oversell incidents recurring → zero through two go-lives (record); no SKU with two published AFS values.
- **Quality** — reserve and lost/found outside S4_Avail — no double-subtract path; the no lives in the FSD as a signed row (record design).

L6 LEVEL EVIDENCE — every line is this story's record or labeled model, no new canon numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	Three meanings of "available" and a request that would have promised unpickable stock; I defined which buckets are inside supply and which sit outside.
Scope & influence	Merchandising, Finance, Digital and Inventory Management each had a stake; I owned none of their systems; three orgs signed.
Execution trade-off + mechanism others own	Visible undersell versus unpickable-stock oversell — chose undersell. Mechanism others own: the FSD row and the Negative AFS / AFS Correction screens.
Impact	Oversell incidents recurring → zero through both go-lives; no SKU promised twice.
Process improvement	A priced no, written as a row; the same break-even shape (p* = cost ÷ (gain + cost)) applies to any reserve decision.
Complexity & consensus	Three node types, two channels, three planning identities, three signing orgs, one comingled pool.
Root cause at scale	Oversell is a vocabulary defect; the fix was a rule about which stock is inside supply, not 441 patches.

PROBING — FIVE FACETS, THEN THE HARDEST FOLLOW-UPS NEW

THE FIVE FACETS — WHERE EACH ONE LIVES IN THIS STORY

1 · Data analysis. Grain: SKU × node × channel × bucket. Sources: the bucket inventory, both books' on-hand, the reserve view Merchandising worked from. Cuts: stock by bucket (inside supply vs outside), by channel demand, by pool. Revealed: stock present in the building and absent from S4_Avail is physical truth the system must not promise.

2 · Solution design. Options: (A) reserve promisable; (B) reserve visible, not promisable (chosen); (C) reserve invisible. A overpromises on a release the floor cannot guarantee; C creates shadow spreadsheets. B gives Merchandising the lever they needed.

3 · Math & data logic. AFS = Basis − PickRes − EcomPick − EcomPack − SNB; MR outside S4_Avail → AFS stays 560 whether MR = 0 or 50. Break-even p* = c ÷ (g + c) = 11 ÷ 30 = 36.7%; EV per unit = p × $19 − (1 − p) × $11.

4 · Implementation. FSD row signed 8/14; matrix cells; visibility view; January/May go-lives; control owners for the screens. Risks: override abuse, vocabulary drift, feed latency (the register's top three).

5 · Probe questions. Below: how you priced it, what if the release is higher, who lost, what you deferred, and the three trap drills.

FACET 5 — PROBE QUESTIONS (CHALLENGE Q&A TUNED TO THIS INTERVIEWER)

Infra — it was in the building. Why not sell it?

Physical presence is not pickability. The reserve is stock Merchandising controls; if it is promised and not released, the customer finds out. I priced it: at a 20% release rate, 10,000 units is −$50K on the cancellation cost alone, −$202K on S1's all-in cost — and it is a customer harm beyond the dollars.

Infra — what release rate would make you say yes?

More than 36.7% on the incremental-cost view, 61.2% on the all-in view. At 40% the incremental EV is +$10K per 10,000 units — thin. I would also want a hold-until date and a release SLA — a rate alone is not a promise.

Infra — who lost?

Merchandising could not sell the reserve in the channel until it was released; they kept full visibility. The comingle-reserve improvements were held out of the release and priced as a later enhancement (master S1); the architecture-council pack had already fenced them out of scope in writing — 'the comingle reserve math stays untouched' (Apple C4).

Infra — how does one pool serve two channels without a split?

Both channels read the same Basis; every event decrements one bucket. Two-pool example: retail 300 with demand 250 (50 idle), dotcom 260 with demand 290 (30 short) — one pool of 560 meets 540 with 20 left. The cost is that the pool's AFS must be right, which is the matrix's job (U1).

Infra — what is the downside of this policy?

Visible undersell: the SKU shows less than the floor could sell. On S1's benchmark undersell costs ≈$4.75 per unit against ≈$30 for an oversell — about 6.3 to 1 — and Inventory Control chases it on the screens. I accept that trade on purpose.

BUSINESS IMPACT MODEL — KPI DRIVERS, BASELINE → AFTER

DRIVER	BASELINE	AFTER	$ / EFFECT	BASIS
Reserve promisable?	requested	no — visible only	−$50K to −$202K avoided per 10,000 units (what-if)	modeled, illustrative
Working definitions of "available"	3	1 signed AFS	—	record
Customer-facing oversell incidents	recurring across 3 node types	zero through two go-lives	S1's ≈$0.9M row is modeled	record / modeled
Stranded stock between pools	30 short while 50 idle (worked SKU)	560 vs 540 demand — 0 short	$570 margin per SKU-week (illustrative)	illustrative
Reserve physically held	2,500 ft³ per 10,000 units	unchanged — not promisable	0.25% of CAP-C's 1.02M ft³	illustrative

THE MATH — FOUR-TABLE DERIVATION (FORMULA → SUBSTITUTION → RESULT) NEW

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Working definitions	`3 (Store · Retail DC · Dotcom DC)`	record	3
2	Worked SKU	`Basis = min(1,000, 980) = 980; AFS = 980 − 200 − 120 − 60 − 40 = 560`	S1 SKU (illustrative); MR outside S4_Avail	AFS 560
3	If the reserve were promisable	`50 reserved units → AFS = 560 + 50 = 610; over-promise exposure if unpickable = 50 units`	illustrative reserve	up to 50 units overpromised
4	Cost per oversell (all-in)	`$6 + $4 + $19 + $1 = $30`	CS contact · refund · lost margin · goodwill (benchmark)	$30
5	Incremental cost (margin never earned)	`$6 + $4 + $1 = $11; gain on a shipped sale = $19`	same inputs, margin removed from the cost side	c = $11, g = $19
6	Two pools — stranded stock	`retail 300 vs demand 250 → 50 idle; dotcom 260 vs 290 → 30 short`	illustrative split of one SKU	30 short, 50 idle
7	Physical footprint of the reserve	`10,000 × 0.25 ft³ = 2,500 ft³`	0.25 ft³/unit (booklet's illustrative); present on the floor, absent from AFS	2,500 ft³

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Break-even release (incremental)	`p* = c ÷ (g + c) = 11 ÷ (19 + 11) = 11 ÷ 30 = 36.7%`	same shape as the booklet's INV-D transfer breakeven (3 ÷ 12 = 25%)	36.7%
2	Break-even release (all-in)	`30 ÷ (19 + 30) = 30 ÷ 49 = 61.2%`	S1's $30 as the cost of a broken promise	61.2%
3	EV per promised unit at p = 20%	`0.20 × $19 − 0.80 × $11 = $3.80 − $8.80 = $-5.00`	release rate illustrative	−$5.00
4	EV per 10,000 units	`−$5.00 × 10,000 = −$50,000`	units illustrative	−$50,000
5	Same, all-in	`0.20 × $19 − 0.80 × $30 = $3.80 − $24.00 = $-20.20; × 10,000 = −$202,000`	S1 all-in cost	−$202,000
6	Option B (chosen)	`AFS = 560 whether MR = 0 or 50; MR shown in ISM, not in published AFS`	record design: MR outside S4_Avail	0 units overpromised
7	One pool, two channels	`300 + 260 = 560 supply; 250 + 290 = 540 demand; 560 − 540 = 20 left; short = 0`	same SKU, one pool	0 short

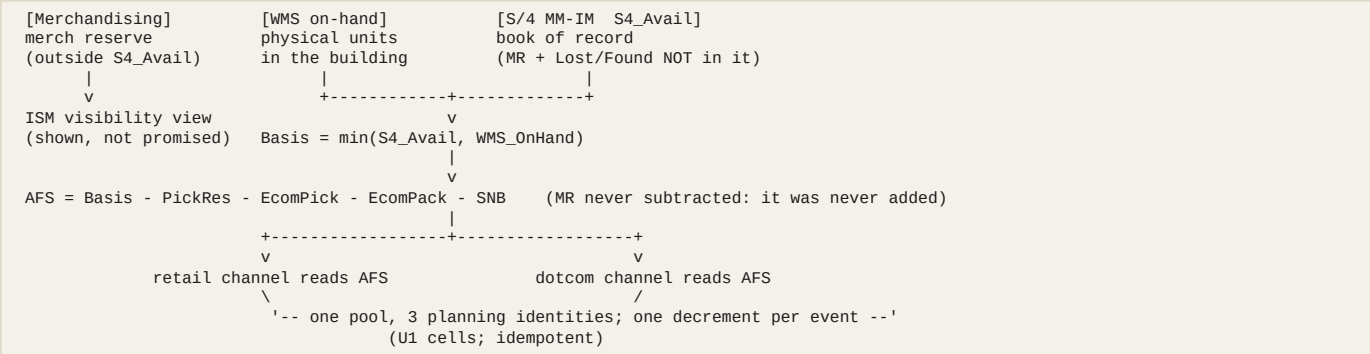

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Working definitions of "available"	3	1 signed AFS	record
2	Reserve units in published AFS	all (the ask)	0	record design
3	Oversell incidents	recurring across 3 node types	zero through two go-lives	record
4	Units short while stock idle (worked SKU)	30 short / 50 idle (two pools)	0 short / 20 left (one pool)	illustrative
5	Reserve rule	meeting minute	a signed FSD row	record

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Expected sales forgone (reserve not promised)	`0.20 × 10,000 × $19 = $38,000`	20% of reserve released and sold at $19 margin	$38,000 not earned
2	Cancellation cost avoided (incremental)	`0.80 × 10,000 × $11 = $88,000`	80% not released → cancelled	$88,000
3	Net, incremental view	`$88,000 − $38,000 = $50,000`	rows 1–2	$50,000 avoided
4	Net, all-in view	`0.80 × 10,000 × $30 = $240,000; − $38,000 = $202,000`	S1 all-in	$202,000 avoided
5	Stranded-stock margin (two pools)	`30 × $19 = $570 per SKU-week`	worked SKU (illustrative)	$570
6	If release were 40%	`0.40 × $19 − 0.60 × $11 = $7.60 − $6.60 = +$1.00/unit → +$10,000 per 10,000`	above p* = 36.7%	+$10,000

SOLUTION FLOW — THE SYSTEM & DATA MAP

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Release rate p (incremental cost)	10% → −$80K	20% → −$50K	40% → +$10K

INPUT	LOW	BASE	HIGH
Cost basis at p = 20%	incremental $11 → −$50K	midpoint $20.50 → −$126K	all-in $30 → −$202K
Reserve volume at p = 20%, $11	5,000 → −$25K	10,000 → −$50K	20,000 → −$100K
Break-even release p*	36.7% (incremental)	—	61.2% (all-in)
Undersell : oversell cost	$4.75 : $30 = 1 : 6.3	—	ratio sets the policy, not one deal

SPOKEN STATEMENT

> "Merchandising asked me to make the reserve promisable. I said no, and I priced the no: promising stock that may not be released is worth it only above about thirty-seven percent release on the incremental cost, sixty-one on S1's all-in cost; on a twenty percent release rate that is about fifty thousand dollars per ten thousand units on the low view and about two hundred thousand on the high view — illustrative inputs, and I show them. What I offered was visibility without promisability, and the no went into the FSD as a signed row. The record is zero customer-facing oversell incidents through both go-lives; the dollars are what that decision would have cost."

IF CHALLENGED

> **"Isn't that just a made-up release rate?"**
> The 20% is illustrative and I tag it. What is not illustrative is the shape: the decision flips only above p* = 36.7% (61.2% all-in). The measurement I would ask Merchandising for is the historical release rate by SKU class.

> **"You priced undersell at $4.75 — where from?"**
> $19 margin × a 25% share of undersold demand that does not come back — both illustrative; it is a 1 : 6.3 asymmetry on S1's benchmark, not a measured number. If the share were 100% the ratio would still be 1.6 : 1 against promising.

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Tell me about a time you disagreed with a stakeholder and held your position.	Have Backbone; Disagree and Commit	The priced no on promisable reserve; visibility offered; the no written as a signed row.	Do not frame it as winning a fight.
Tell me about a time you protected the customer at a cost to the business.	Customer Obsession	Visible undersell accepted so oversell is zero by construction; asymmetry 1 : 6.3.	Do not claim the dollars as saved.
How do you decide whether to promise stock that is physically present?	Functional — promise design	Pickable vs present; p* = c ÷ (g + c); the promise reads published AFS, never computes.	Never 'I configured ISM'.
Tell me about a time you considered the broader impact.	Success and Scale Bring Broad Responsibility	Oversell as a customer harm at scale; the dollar price is the floor, not the whole.	Do not invent a customer count.

BEHAVIORAL PACK — FOUR SEPARATE 90-SECOND STAR ANSWERS, EACH FROM A DIFFERENT MOMENT OF THE STORY NEW

HAVE BACKBONE; DISAGREE AND COMMIT · AIQB Q1 **Q1. "Tell me about a time when you strongly disagreed with your manager or peer on something you considered very important to the business."**

Merchandising wanted the merch reserve to be promisable — stock in the building, why not sell it? I disagreed, but not by arguing. I priced the ask: promising a unit that may not be released only pays if more than about 37% of reserved units actually are released; on a 20% release rate that is about minus fifty thousand dollars per ten thousand units on the cancellation cost alone and about minus two hundred thousand on S1's all-in cost. Then I offered what they actually needed: visibility — the reserve shown, not promised. The no went into the FSD as a row signed by Strategy, Inventory Management and Inventory Accounting, so it was a decision, not a meeting minute that would be re-litigated weekly. The comingle-reserve improvements were held out of the release to protect zero incidents and priced as a later enhancement at steering. I disagreed once, with a number, and committed in writing.

Number to land: p* = 36.7%; −$50K to −$202K per 10,000 units (illustrative) · **Pivot to NACF:** At NACF the same break-even decides when to promise ahead of a physical state — received-not-stowed, in transit — a number, not a feeling. · **Do NOT say:** that I won; that the dollars are saved; that the release rate was measured.

CUSTOMER OBSESSION · AIQB Q7 **Q2. "Sometimes customers make unreasonable requests. Tell me about a time when you've had to push back or say no to a customer request."**

I accepted visible undersell so that oversell would be zero by construction. The design policy was an asymmetry: an oversell is a customer defect — someone pays for something we do not have — and an undersell is a planning variance Inventory Control chases. On S1's benchmark one oversell costs about thirty dollars and an undersold unit about five, roughly a six-to-one asymmetry, so the supply basis is the lower of the two books and the reserve never enters it. That means some sellable stock shows as unavailable. I said so in the FSD and made the control owners own the screens that chase it. The result: customer-facing oversell incidents that were recurring across three node types went to zero through both go-lives. The cost of the policy is visible undersell, which I will always take over a broken promise.

Number to land: oversell incidents recurring → zero; asymmetry ≈ 1 : 6.3 · **Pivot to NACF:** At NACF a promise date is a customer commitment; I would take a slightly conservative buffer over a missed date on the same arithmetic. · **Do NOT say:** a customer count; that undersell is free.

EARN TRUST · AIQB Q3 **Q3. "Describe a time when you needed to influence a peer who had a differing opinion about a shared goal."**

The relationship was the reason I started with what Merchandising needed, not what they asked for. They asked for the reserve to be promisable; what they needed was to see it and to know when it could be released. So the first thing I said was yes: yes to visibility, in ISM, alongside AFS. Then I said no to the mechanism and showed my arithmetic — the break-even and the cancellation cost — so the no was not an opinion. I made the cost to them explicit: the reserve could not be sold in the channel until released. I put the no into the FSD as a row so nobody had to defend it in a hallway, and the comingle-reserve improvements were held out of the release and priced rather than refused. The FSD was signed by three orgs (user anchor, master S1) with the row in it. The test of trust is that the no was written down and the offer was real.

Number to land: 3 orgs signed the row · 0 open 'who owns this bucket' (both user anchor) · **Pivot to NACF:** At NACF I would open every no with the need I can say yes to and the number that makes the no checkable. · **Do NOT say:** that Merchandising agreed happily; I do not know their private view.

SUCCESS AND SCALE BRING BROAD RESPONSIBILITY · AIQB Q5 **Q4. "Tell me about a time when you considered everyone who was affected by your work, not just your direct customers or people within your organization."**

An oversell looks like a ledger error to a planner and a broken promise to a customer. At the scale of this DC — an illustrative thirty million orders a year at a benchmark 0.10% oversell rate — that is thirty thousand customers a year who paid for something we did not have. I did not let the dollar comparison be the whole argument for the no on promisable reserve. The dollar figure — fifty to two hundred thousand per ten thousand reserved units — is the floor of the case; the rest is what it does to a customer's trust in a promise. So the design treats a broken promise as a defect with an owner and a screen, not a variance to be tolerated. The record: customer-facing oversell incidents zero through two go-lives. At Amazon scale that is the difference between a rare event and a daily one.

Number to land: 30,000 incidents/yr (illustrative) → 0; zero through two go-lives · **Pivot to NACF:** At NACF a promise date on a Prime order is the same contract; I would run the same defect-not-variance logic on the promise seam. · **Do NOT say:** a real customer count; that 30,000 is measured — it is S1's illustrative orders × benchmark rate.

SAME STORY, THREE ANGLES — DATA · CONFLICT/INFLUENCE/BACKBONE · FAILURE-LEARNING NEW

DATA ANGLE · DIVE DEEP	CONFLICT / INFLUENCE ANGLE · HAVE BACKBONE; DISAGREE AND COMMIT	FAILURE / LEARNING ANGLE · EARN TRUST
"I turned a stakeholder request into a break-even: promise the reserve only above 37% release." **Headline metric:** p* = 36.7% (61.2% all-in); −$50K per 10,000 units at 20% The decision is a one-line formula, p* = c ÷ (g + c), with two cost views; it flips only if the release rate is measured above the break-even. Honest limit: the 20% release rate is illustrative.	*"Merchandising wanted something I would not give them — so I gave them everything else."* **Headline metric:** visibility yes · promisability no · 3 orgs signed (user anchor) Priced no; visibility offered; the no written as an FSD row; the comingle-reserve improvements held out and priced as a later enhancement.	*"I priced the no with a release rate I never measured."* **Headline metric:** release rate 20% illustrative vs p* = 36.7% The row in the FSD carried the decision, but not the measurement that would flip it: the historical release rate by SKU class. Do differently: put the ask for that measurement in the same row.

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS, WITH NUMERIC ANSWERS NEW

How do you know it was the right call and not just caution?

It is right as long as the release rate is below 36.7% (61.2% all-in). The record is zero oversell incidents; I cannot prove the counterfactual. The number that would change my mind is a measured release rate above the break-even with a hold-until date.

Say: *"The decision is right below a 37% release rate; I did not measure it, so the row I would add is that measurement — if it came back above 37%, I would reopen it."*

Isn't splitting the cost into $11 and $30 a way to get the answer you want?

No — the decision holds on both: −$50K and −$202K per 10,000 units at 20%. It flips only above p* in either view, and the two views bracket it between 36.7% and 61.2%.

Say: *"I show both cost views because the answer does not depend on which you believe — it depends on whether the release rate is above 37% or 61%."*

Who bore the cost of your no?

Merchandising: for a period the reserve was visible but not sellable in the channel until released; the comingle-reserve improvements were deferred and priced at steering.

Say: *"Merchandising bore it — visible but not sellable until release; the comingle-reserve improvements were held out of the release to protect zero incidents and priced, not promised."*

20-SECOND VERSION + NACF BRIDGE NEW

20-second version. At the Utah DC I said no to making merch reserve promisable — stock in the building but not for sale — by pricing the no: it pays only above about 37% release, which on a 20% illustrative rate is −$50K per 10,000 units. I offered visibility instead, wrote the no into the FSD, and customer-facing oversell went to zero through both go-lives.

NACF bridge. NACF has the same seam on the dock: units received but not yet stowed, quarantined or in transit are in the building and not pickable. The promise should read pickable; p* = cost ÷ (gain + cost) — INV-D's 3 ÷ 12 = 25% shape — says when promising ahead of the stow pays. 10,000 reserved units at 0.25 ft³ = 2,500 ft³: CAP-C's cube in miniature.

U4 — Where the node's constraint actually bound — labor hours, then pick accuracy, then cube: one capacity envelope that priced the robotics throttle and the pooled space NEW

LPs this story serves here: Bias for Action (primary — the throttle decision the week the gate failed) · Frugality (price both sides; pay for the cheaper one) · Dive Deep (the constraint was accuracy, not robot speed) · Strive to be Earth's Best Employer (the floor protected during the ramp)
Process family: Make / Deliver — DC capacity and throughput analysis: labor-hour envelope, automation ramp, constraint identification, cube

Honesty label. Record: robotics gate 98% published before the ramp; week two at 94%; bots throttled to ~30% of volume for a week; zone/slotting logic root-caused; full volume week three; +15% processing efficiency (Sephora-signed, measured by DC Ops); DC Ops owned the gate and the dial; peak (Oct–Dec) untouched. **Modeled / illustrative (S2's DC):** 100,000 units/week, 120 FTE × 2,000 h, $28/h. **Mine to label:** $12 per mis-pick, linear hours-versus-bot-share, 10,000 attempted picks, $25 per unit and 0.25 ft³ per unit — all illustrative. I priced the trade; DC Ops ran the floor; I do not claim whose budget carried the hours.

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH

Bias for Action. The week-2 read was 94 against a published 98; the dial, built in advance and owned by DC Ops, went to ~30% the same week — a reversible decision with a number.

Frugality. I priced both sides: ≈$11.8K of extra labor hours against ≈$50.4K of mis-pick exposure, and paid the cheaper one with existing labor — no new tooling.

Dive Deep. The robots could pick; they could not pick right — the binding constraint at week 2 was accuracy, root-caused to zone and slotting logic, not robot speed.

Strive to be Earth's Best Employer. The throttle kept the floor from absorbing the mis-picks and the rework; the interim reporting burden was named as the price. No headcount or attrition figure is claimed.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. Sephora's Utah DC was ramping Locus robotics behind a published 98% pick-accuracy gate, on an illustrative 100,000-units-a-week floor running 4,615 labor hours a week. Week two read 94%. **Task.** Decide, with DC Ops, how much robot volume the floor could carry — and where the node's constraint actually sat. **Action.** Analysis first: before the ramp the binding constraint was labor hours; in week two it had moved to accuracy, not robot speed. Four points of accuracy at full bot share is 6,000 mis-picks a week against a 2,000 budget. I priced the dial: a throttle to 30% keeps bot-side errors at 1,800, inside the full-volume budget — the maximum safe share is 33.3% — at a cost of about 421 extra labor hours, roughly $11,800, against about 4,200 mis-picks avoided, roughly $50,400 on an illustrative $12 each. DC Ops owned the dial before the ramp, so the rule fired and I did not improvise. Zone and slotting logic was root-caused and fixed; full volume in week three. Pooling had freed the safety stock the node did not need to hold — about $2.2M modeled, roughly 22,000 cubic feet on illustrative unit cube. **Result.** Primary metric: the gate held — 94 against 98 became full volume in week three, with +15% processing efficiency Sephora-signed and zero customer-facing incidents. The dollars are a model; the gate, the throttle and the +15% are the record.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — One physical node, one robotics ramp, one published gate. The floor was running at baseline productivity (index 100); the plan was +15% at stabilization; the robots were the lever. The week-2 gate read 94 against 98 with the Oct–Dec peak freeze ahead. Everyone could see the gap; nobody had a number for what each response would cost.

T — Say where the constraint bound and what each dial setting cost, on one page, in the week it mattered — and make sure the rule that fired was the floor owner's, not mine.

Baselines on the table: gate 98% (record) · week 2 = 94% (record) · 240,000 h/yr = 4,615 h/wk on an illustrative 100K-units/week node · target index 115 → 4,013 h/wk · full-share exposure 6,000 mis-picks vs a 2,000 budget · peak freeze Oct–Dec.

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery (3/29 → 4/30)** — profiled 801/901; read the node's labor and throughput as an envelope — hours per week, units per hour, what the floor could ship; success criteria included peak untouched. *Exit bar:* criteria signed by steering; every impacted system owned.
- **Plan & Design (5/15 → 8/14)** — wrote the gate (98% pick-accurate completed ÷ attempted), the throttle dial and the weekly read in the council pack before the robots arrived; DC Ops took ownership of the gate and the dial. *Exit bar:* council 7/31; FSD 8/14; the dial owned before the ramp.
- **Build & Test (Aug → Jan/Apr)** — the Locus gate definition and throttle spec in the build; the 3-day Locus workshop; RTL slipped three weeks, escalated the week it surfaced, re-slotted openly, UAT not compressed. *Exit bar:* Locus RTL retested after the slip; E2E days

dated.

- **Cutover & Go-Live (January; May 1 → Jul 1)** — ramp read weekly; week 2 = 94 against 98 → throttle to ~30% for a week → zone/slotting RCA → week-3 re-read at the same gate. *Exit bar:* rule fired; full volume week 3.
- **Hypercare / Close (Jun → Jul)** — +15% measured post-stabilization by DC Ops; hypercare exit week 3 of 4; the dial and the gate handed to the next DC as a template. *Exit bar:* exit at < 2 blockers/day sustained.

Influence and ownership. Mine: the capacity envelope, the dial arithmetic and the go/no-go on the ramp read. DC Ops: the gate, the dial, the floor and the +15% measurement. Locus and platform teams: the build and the slotting fix.

> **Designed the process; others own it now.** DC Ops owns the dial and the weekly read; the template went to the next DC. **Trade-off put to leadership:** a week of robot volume for a root-caused ramp — recommended with the arithmetic on both sides.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY

- **$** — modeled on S2's illustrative DC: throttle premium ≈421 h × $28 = $11,799 against ≈4,200 mis-picks × $12 = $50,400 avoided; break-even mis-pick cost $2.81. Pooled safety stock released ≈$2.2M ≈ 22,000 ft³ (modeled). Not claimed as savings.
- **#** — gate 98%, week 2 at 94%, throttle ~30% for one week, full volume week 3 (record); 4,615 → 4,013 labor hours/wk at +15% (modeled on the record index).
- **%** — +15% processing efficiency (record, Sephora-signed); max safe bot share 33.3% against the ~30% dial (arithmetic).
- **Time** — one week at ~30%; week-3 re-read at the same gate; hypercare exit week 3 of 4; ~92 days of float from Jul 1 to the Oct freeze (lower bound).
- **Customer** — zero customer-facing incidents through both go-lives; peak untouched (record).
- **Quality** — the gate stayed a gate — it fired at 94 and was re-read at the same number; the cause (zone/slotting logic) was removed, not routed around.

L6 LEVEL EVIDENCE — every line is this story's record or labeled model, no new canon numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	No agreed stop condition for the ramp. I defined the gate, the dial and the weekly read before the robots arrived.
Scope & influence	DC Ops owned the floor and the dial; Locus and platform teams the build; I owned the envelope and the recommendation.
Execution trade-off + mechanism others own	A week of robot volume for a root-caused ramp; the mechanism others own: the dial and the weekly read.
Impact	+15% processing efficiency; full volume week 3; peak untouched; zero incidents.
Process improvement	Gate → dial → RCA → re-read as standard work for the next DC.
Complexity & consensus	WMS upgrade, robotics and peak freeze on one critical path; Operations, IT and Supply Chain Strategy in steering.
Root cause at scale	The week-2 miss was zone/slotting logic — fixed at the cause before full volume.

PROBING — FIVE FACETS, THEN THE HARDEST FOLLOW-UPS NEW

THE FIVE FACETS — WHERE EACH ONE LIVES IN THIS STORY

1 · Data analysis. Grain: node × week × bot share. Data: labor hours, units, attempted and accurate picks, mis-pick cost. Cuts: accuracy by week; hours by share; exposure by share. Revealed: the constraint had moved from labor hours (pre-ramp) to accuracy (ramp) — robot speed was never the binding limit.

2 · Solution design. Options: (A) hold full volume and fix live; (B) throttle to 0 and re-test later; (C) throttle to ~30% and keep re-reading. Chose C — A's exposure is 4,000 mis-picks over budget; B costs ≈$5.1K more and loses the live volume the gate reads.

3 · Math & data logic. hours(s) = $H_0 - s(H_0 - H_1)$; premium = $(1 - s)(H_0 - H_1)$; errors = 6% × s × volume; s_max = (1 − 0.98)/(1 − 0.94) = 33.3%; z = 0.04/√(0.98 × 0.02/n).

4 · Implementation. Gate and dial published and owned by DC Ops before the ramp; weekly read; RCA; re-read; hypercare exit. Risks: ramp with no stop condition, two live truths, peak collision.

5 · Probe questions. Below: why 30, why not 0, is 94 noise, where was the constraint, and the three trap drills.

FACET 5 — PROBE QUESTIONS (CHALLENGE Q&A TUNED TO THIS INTERVIEWER)

Infra — why a 30% throttle, not 0% or 50%?

At 30% the bot-side errors are 1,800, inside the 2,000-per-week budget the gate allows at full volume; the maximum safe share is 33.3%. At 50% errors would be 3,000 — over. At 0% the premium rises to ≈$16.9K and the gate has no live bot volume to read.

Infra — is 94 versus 98 noise?

No. On an illustrative 10,000 attempted picks the standard error is 0.14 points and the gap is 28.6σ; even on 500 picks it is 6.4σ. The week-2 read was a real miss, not sampling.

> **Infra — where did the node's constraint actually bind?**
>
> Pre-ramp: labor hours — 4,615 h a week for 100K units. In the ramp: accuracy, not robot speed — the zone/slotting logic. After: labor again, at +15% — 4,013 h. I did not claim space bound; I do not know the Utah cube utilization VERIFY-WITH-RAJESH.

> **Infra — what did the throttle cost, and who paid?**
>
> About 421 extra labor hours ≈ $11,799 on the illustrative $28 — about 10.5 FTE-weeks at 40 hours. I do not claim whose budget carried them; DC Ops ran the floor.

> **Infra — did the throttle create a backlog?**
>
> Not on this arithmetic: at fixed baseline hours the node's capacity under a 30% share is ≈104,072 units a week against 100,000 — 4.1% headroom. It is a linear model; the real node's hours were not fixed.

BUSINESS IMPACT MODEL — KPI DRIVERS, BASELINE → AFTER

DRIVER	BASELINE	AFTER	$ / EFFECT	BASIS
Bot share (week 2)	100% planned	~30% (record)	errors 6,000 → 1,800	record / arithmetic
Pick accuracy (gate)	94% (week 2)	≥98% re-read week 3	full volume	record
Labor hours per week	4,615	4,013 at index 115	−602 h/wk	modeled on record +15%
Throttle week premium	—	+421 h	$11,799 vs $50,400 avoided	modeled / illustrative
Cube equivalent of pooled release	—	22,000 ft³	≈2.2% of CAP-C's 1.02M ft³	illustrative

THE MATH — FOUR-TABLE DERIVATION (FORMULA → SUBSTITUTION → RESULT) NEW

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Baseline weekly hours	`240,000 / 52 = 4,615.4 h/wk; 100,000 / 4,615.4 = 21.67 units/h`	120 FTE × 2,000 h; 100K units/wk (S2 illustrative)	4,615 h/wk
2	Gate vs week-2 read	`98% − 94% = 4 pts`	record	4 pts short
3	Exposure at full bot share	`6% × 100,000 = 6,000 mis-picks; budget at the gate 2% × 100,000 = 2,000; excess = 4,000`	94% vs 98% on illustrative volume	4,000 over budget
4	Is it noise?	`SE(n=10,000) = √(0.98 × 0.02 / 10,000) = 0.0014; z = 0.04 / 0.0014 = 28.6`	10,000 attempts illustrative; z(n=500) = 6.4	28.6σ
5	Where the constraint bound	`pre-ramp: labor (21.67 u/h × 4,615 h = 100,000); ramp: accuracy T = 94% < 98%`	robot speed was not binding	accuracy
6	Calendar float	`Jul 1 → Oct 1 = 31 + 31 + 30 = 92 days`	peak freeze Oct–Dec (record); start date VERIFY	92 days (lower bound)

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Max safe bot share	`s_max = (1 − 0.98) / (1 − 0.94) = 0.02 / 0.06 = 33.3%`	bot-side errors ≤ the full-volume error budget	33.3%
2	Dial = ~30% (record)	`errors = 6% × 30,000 = 1,800 ≤ 2,000; avoided = 6,000 − 1,800 = 4,200`	inside the budget by 200	4,200 avoided
3	Hours at 30% share	`0.7 × 4,615.4 + 0.3 × 4,013.4 = 3,230.8 + 1,204.0 = 4,434.8`	linear in bot share (illustrative)	4,434.8 h
4	Premium vs plan	`4,434.8 − 4,013.4 = 421.4 h = 10.5% of plan hours ≈ 10.5 FTE-weeks`	40-h week (illustrative)	421.4 h
5	Capacity at fixed hours	`100,000 × 4,615.4 / 4,434.8 = 104,072 units/wk`	baseline hours held	104,072 (no backlog)
6	Upper bound premium	`0% share: 602.0 h × $28 = $16,856`	full manual week	≈$16.9K
7	Re-read	`week 3: T ≥ 98% at the same gate → full volume`	record	full volume week 3
8	Space — what pooling freed	`$2.2M / $25 = 88,000 units; × 0.25 ft³ = 22,000 ft³`	$25/unit and 0.25 ft³ illustrative	22,000 ft³

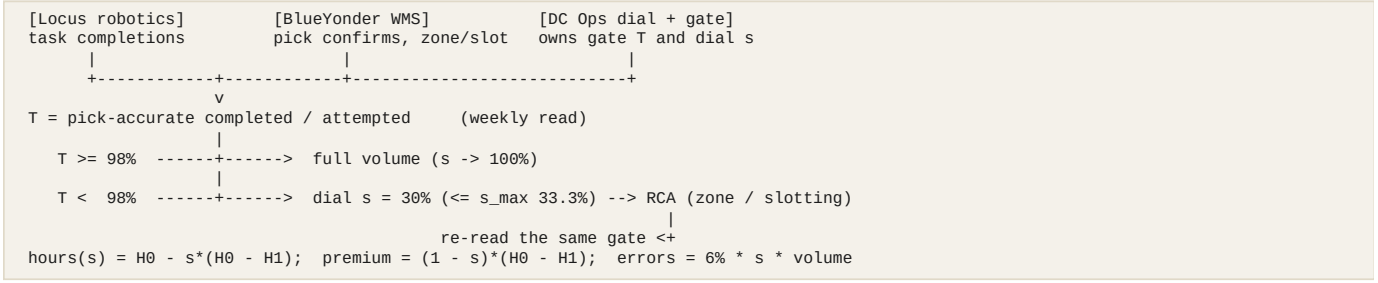

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Bot share, week 2	100% planned	~30%	record
2	Pick accuracy	94%	≥98% at week-3 re-read	record
3	Full-share mis-picks / wk	6,000	≤2,000 at the gate	illustrative volume
4	Labor hours / wk (same volume)	4,615	4,013 (index 115)	modeled on record +15%
5	Customer-facing incidents	0 allowed	0 through both go-lives	record

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Throttle premium	`421.4 h × $28 = $11,799`	$28 loaded (modeled)	≈$11.8K
2	Mis-picks avoided, priced	`4,200 × $12 = $50,400`	$12 per mis-pick (illustrative)	≈$50.4K
3	Net	`$50,400 − $11,799 = $38,601`	rows 1–2	≈$38.6K
4	Ratio and break-even	`$50,400 / $11,799 = 4.3×; break-even cost per mis-pick = $11,799 / 4,200 = $2.81`	decision holds above $2.81	4.3× / $2.81
5	Premium as share of the annual labor benefit	`$11,799 / $876,400 = 1.35%`	S2's ≈$0.88M/yr (modeled)	1.35%
6	Upper-bound premium	`602.0 h × $28 = $16,856`	0% share	≈$16.9K

SOLUTION FLOW — THE SYSTEM & DATA MAP

Break-even mis-pick cost	—	$2.81	decision holds above this

SPOKEN STATEMENT

> "Before the robots arrived the node's binding constraint was labor hours; in week two it was accuracy — 94 against a published 98 — not robot speed. On an illustrative hundred-thousand-unit week that is about 4,000 mis-picks over the gate's budget at full share. A throttle to 30% kept the errors inside the budget, because the maximum safe share is 33%, at a cost of about 420 extra hours, roughly twelve thousand dollars, against about fifty thousand dollars of mis-picks avoided — modeled, on a twelve-dollar mis-pick I label illustrative. DC Ops owned the dial, so the rule fired; the zone and slotting logic was fixed and week three ran at full volume. The +15% and the zero incidents are the record."

IF CHALLENGED

> **"The $12 mis-pick cost is invented."**
>
> Yes, illustrative — and the decision does not depend on it: the throttle pays above $2.81 per mis-pick, so the answer holds across any plausible cost. The record is the gate, the dial and the week-3 re-read.

> **“You only fixed it because the slotting logic was wrong — the throttle was irrelevant.”**
>
> Two levers: the throttle bounded exposure while the fix was made; the fix removed the cause. I cannot separate their contributions in the record, and I would not claim to — but the dial let the re-test run on live volume.

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Tell me about a time you made a fast decision with imperfect data.	Bias for Action	Week-2 read; dial pre-built; ~30% the same week; reversible.	Do not say ‘the robots failed’.
Tell me about a time you did more with less / priced a trade-off.	Frugality	$11.8K vs $50.4K with existing labor; 4.3×; break-even $2.81.	Do not claim the dollars as savings.
How do you identify where the constraint is?	Dive Deep / Functional	Labor hours → accuracy → labor; speed was never binding.	Never claim space bound — unknown.
How did you protect the people on the floor?	Strive to be Earth’s Best Employer	Throttle kept mis-picks and rework off the floor; DC Ops owned the dial; interim reporting burden named.	Invent no headcount or attrition.

BEHAVIORAL PACK — FOUR SEPARATE 90-SECOND STAR ANSWERS, EACH FROM A DIFFERENT MOMENT OF THE STORY NEW

BIAS FOR ACTION · AIQB Q1 **Q1. “Give me an example of a calculated risk that you have taken where speed was critical.”**

Week two of the robotics ramp read 94 against a published 98. The gate was published before the robots arrived, and DC Ops owned the throttle dial, so I did not need a meeting to decide whether to act; I needed to decide how far to turn the dial. I priced it that week: at full bot share four points of accuracy is about 6,000 mis-picks a week against a 2,000 budget; a throttle to 30% keeps the bot-side errors at 1,800, inside the budget — the maximum safe share is 33.3% — and costs about 420 extra labor hours. The decision was reversible: re-read the same gate in a week. I dialed to roughly 30%, root-caused the zone and slotting logic, and ran full volume in week three. Speed came from the decision being built before the pressure arrived.

Number to land: 94 vs 98 → ~30% dial → full volume week 3 · **Pivot to NACF:** At NACF the same pattern — a published ceiling, a pre-built reversible response, a weekly re-read — applies to a new FC’s inbound ramp. · **Do NOT say:** that the robots failed; that the dial was my invention — DC Ops owned it.

FRUGALITY · AIQB Q4 **Q2. “Tell me about a time when you had to make tradeoffs between quality and cost.”**

I did not buy a fix; I priced a setting on a dial that already existed. The choice in week two was between running at full volume and absorbing the mis-picks, or slowing the bots and covering the volume with the floor’s existing labor. I put both on one page: the throttle costs about 421 hours — roughly eleven thousand eight hundred dollars at an illustrative $28 — and avoids about 4,200 mis-picks, which is fifty thousand dollars at twelve dollars each, or any cost above about two dollars eighty. That is 4.3 to 1 on illustrative inputs. No new tooling, no new heads; the dial existed because DC Ops and I had built it before the ramp. And the pooled safety stock freed about 22,000 cubic feet of space the node no longer had to hold. The record is the gate holding and the +15%; the dollars are my model and I say so.

Number to land: ≈$11.8K vs ≈$50.4K (4.3×); break-even $2.81 · **Pivot to NACF:** At NACF a node’s constraint is priced the same way — flex labor against dwell, CAP-B and CAP-E — before any new capacity is bought. · **Do NOT say:** that the $12 or the $28 is measured; that this was a saving.

DIVE DEEP · AIQB Q3 **Q3. “Tell me about a problem you had to solve that required in-depth thought and analysis.”**

Everyone assumed the question was how fast the robots could go. The data said the constraint had moved. Before the ramp the node was bound by labor hours — 4,615 a week for 100,000 units. In week two the robots were picking; they were not picking accurately: 94 against 98. At a full bot share that is thousands of mis-picks, and more robot speed would have made it worse. I asked what was different about the misses, and the answer was the zone and slotting logic — the cause was in how work was assigned, not in the robots. So the fix went to the logic, and the throttle bought the time. After the fix and the week-three re-read at the same gate, the constraint went back to labor hours — now at +15%, about 4,013 a week. The mistake I avoided was optimizing the non-binding constraint.

Number to land: constraint: labor → accuracy → labor; 94 vs 98; +15% · **Pivot to NACF:** NACF’s capacity chain is the same — doors, UPH, cube, dwell — and the first job is to find which one binds this week. · **Do NOT say:** that I fixed the slotting logic myself; the platform team did.

STRIVE TO BE EARTH'S BEST EMPLOYER · AIQB Q3 **Q4. “Describe a time when you implemented a change at work aimed at improving the work experience of yourself or coworkers.”**

The floor was the one place the cost of a bad ramp would land. If the bots had stayed at full volume at 94% accuracy, every mis-pick becomes rework for someone on the floor, during a go-live. I wrote the gate and the dial before the ramp, and DC Ops owned them — so the people who knew the floor held the stop condition, not a program manager on a schedule. When the gate fired, the throttle kept the mis-picks and the rework off the floor for a week while the logic was fixed. I also named the price of the interim to leadership: for four months every report had to declare which system of record it read. I will not quote a headcount or an attrition number — there is none in the record — but the design principle is the stop condition belongs to the people who carry the consequence.

Number to land: the dial owned by DC Ops before the ramp · **Pivot to NACF:** At NACF the same principle applies to a peak ramp — the dock and the floor own the stop condition for their own safety and quality. · **Do NOT say:** a headcount, an attrition or a safety figure — none exists in the record.

SAME STORY, THREE ANGLES — DATA · CONFLICT/INFLUENCE/BACKBONE · FAILURE-LEARNING NEW

DATA ANGLE · DIVE DEEP	CONFLICT / INFLUENCE ANGLE · HAVE BACKBONE; DISAGREE AND COMMIT	FAILURE / LEARNING ANGLE · OWNERSHIP
"Four points of accuracy is 6,000 mis-picks a week at full share against a 2,000 budget." **Headline metric:** s_max = 33.3% vs ~30% dial; 28.6σ The throttle share has a maximum that falls out of the gate (0.02/0.06). The record's ~30% sits just inside it. The misses were not noise (28.6σ on an illustrative 10,000 attempts). Honest limit: the volume and mis-pick cost are illustrative.	*"Letting a 94% system carry full volume was the path of least resistance; the gate was published before that temptation existed."* **Headline metric:** 94 vs 98; dial ~30% Holding the gate was enforcement, not escalation; the trade was visible in dollars on both sides. Record: the alternative — a 94% system carrying full volume into the combined go-live — is how an incident with a robot in the photo happens.	*"I had the Locus RTL on the plan as a task, not as a risk."* **Headline metric:** 3-week RTL slip; 94 vs 98 The slip was escalated the week it surfaced and re-slotted openly without compressing UAT, but it had no trigger or owner on the register at the start. Do differently: put vendor RTL on the register as a risk from day one, and publish the zone/slotting test as a gate prerequisite.

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS, WITH NUMERIC ANSWERS NEW

How do you know the throttle — and not the slotting fix — got you to 98?

I don't, and I would not claim to. The throttle bounded exposure at 1,800 errors against a 2,000 budget while the fix was made; the fix removed the cause; the week-3 re-read at the same gate is the evidence of the combination.

Say: *"I can't separate them; the throttle bought exposure control and the time to test the fix on live volume, and the week-3 re-read is the evidence of both."*

Why not 0%? Why not 50%?

At 50% errors are 3,000 against 2,000 — over budget. At 0% the premium is ≈$16.9K instead of ≈$11.8K and the gate has no bot volume to read. 30% sits inside the 33.3% maximum.

Say: *"Thirty is just inside the maximum safe share of thirty-three; fifty breaks the error budget and zero costs five thousand more with nothing to re-read."*

What is the number that would have changed your mind?

A mis-pick cost below $2.81: the throttle would not pay on the arithmetic. Or a re-read at week 3 still below 98: the dial stays, and the RCA reopens.

Say: *"Below about three dollars a mis-pick the throttle doesn't pay, and a week-three read under 98 would have kept the dial down."*

20-SECOND VERSION + NACF BRIDGE NEW

20-second version. In week two of Sephora's robotics ramp the gate read 94 against a published 98; the constraint had moved from labor hours to pick accuracy, and a pre-built, DC-Ops-owned throttle to about 30% — inside the 33.3% maximum safe share — cost about 421 labor hours against roughly 4,200 mis-picks avoided, and full volume ran in week three.

NACF bridge. NACF's inbound capacity chain has the same shape: CAP-A doors held at an 85% ceiling because above it dwell goes about 3×, CAP-B's learning curve costing 13.6% more hours — the throttle week was +10.5% — and CAP-E's ~14 flex heads. The throttle's 421 hours is about ten and a half people for a week; the question for any new FC ramp is which of doors, UPH or cube binds this week, and who owns the dial.

U5 — The 343-task cutover runbook with one irreversible instant — priced rollback triggers, a three-SKU zero-then-publish trace, and what a week of slip is worth NEW

LPs this story serves here: Ownership (primary — the go/no-go and the rollback were mine to recommend) · Deliver Results (a 61-day window, peak untouched) · Have Backbone (no UAT compression; no-go on one open Blocker) · Dive Deep (the runbook arithmetic and the trace)
Process family: Deliver — cutover and go-live design: runbook, sequencing, rollback triggers, hypercare exit

Honesty label. Record: runbook 343 tasks / 48,885 task-minutes ≈ 815 hours, May 1 → Jul 1, each task with owner, duration and predecessor; six-step May choreography with step 4 (zero-then-publish) the one irreversible instant — I can name steps 1–4: clear negatives, transfer AFS to Uncommitted, scan-and-reserve, zero-then-publish **steps 5 and 6 not in the packet**; six invariants — I can name three (Σ AFS conserved; no SKU sellable on 800 and 900 at once; negatives cleared first) **other three not in the packet**; rollback triggers sync < 99% for four consecutive hours or order-flow p95 > 2× budget for one hour, consumers revert to the prior publish; armed for both go-lives, never fired; Blocker + Critical open = 0; mock 3 inside the 0.5% tolerance; monthly new-row arc 271 → 65 → 21 → 14 → 4 (June → October); hypercare exit week 3 of 4. **Modeled / illustrative:** the three-SKU trace, $110/h, 100K units/week, $30 per incident. User anchor, loop packet only (not in Apple or the master): the day-one pace in units. The weekly discovery curve is computed from the log. I built the runbook and recommendation; platform, DC Ops and vendor teams executed.

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH

Ownership. The go/no-go recommendation, the runbook and the rollback triggers were mine; I wrote the recommendation off counted rows and I would have called no-go on one open Blocker.

Deliver Results. A 343-task, ~815-hour runbook ran inside a 61-day window with the peak freeze untouched: two go-lives, zero customer-facing incidents, hypercare exit week 3 of 4.

Have Backbone; Disagree and Commit. When the Locus RTL slipped three weeks I escalated the week it surfaced, re-slotted openly, and refused to compress UAT to absorb it.

Dive Deep. I read the cutover as arithmetic — task-hours, trigger exposure, a three-SKU trace — so every threshold had a number behind it.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. Sephora's Utah DC cutover moved warehouse execution from two systemic warehouses to one comingle pool between May 1 and July 1, with zero customer-facing incidents allowed, an October–December peak freeze behind it, and about a dozen impacted systems in the path. **Task.** Own the runbook and the recommendation — what has to happen, in what order, who does it, and what makes us stop. **Action.** I built a 343-task, 48,885-minute — about 815-hour — runbook, each task with an owner, a duration and a predecessor; found the single irreversible instant, step 4, zero-then-publish, so no SKU was ever sellable on both selling locations at once; and wrote the rollback triggers as numbers per interface: sync below 99% for four consecutive hours, or order-flow p95 above twice the budget for an hour, consumers reverting to the prior publish. I wrote the go/no-go off counted rows — Blocker plus Critical at zero, mock three inside the 0.5% tolerance, runbook rehearsed — and I would have said no-go on one open Blocker. Hypercare was read as a decaying monthly arc of new issue rows, 271 → 65 → 21 → 14 → 4, and exited at under two blockers a day sustained. **Result.** Primary metric: zero customer-facing incidents through both go-lives, rollback armed twice and never fired. The runbook cost about $90,000 of effort at an illustrative $110 an hour — less than three weeks of the modeled benefit it protected.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — A multi-system cutover in a fixed window: BlueYonder upgrade, comingle reserve rules, robotics ramp and about a dozen impacted systems moving the same two months, with the peak freeze behind it and no room for a customer-facing incident. The interim ran two live truths.

T — Write the runbook that makes the cutover a sequence of owned tasks, identify the instant that cannot be undone, and fix the stop conditions in numbers before anyone is tired.

Baselines on the table: 343 tasks · 48,885 task-minutes ≈ 815 h · 61 days · one irreversible instant · rollback triggers per interface · mock 3 ≤ 0.5% · Blocker + Critical open = 0 · hypercare exit at < 2 blockers/day.

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery (3/29 → 4/30)** — systems-impacted table with owner and written LOE per row; the interim-state risks named — two live truths, a ramp with no stop condition, a peak collision. *Exit bar:* every impacted system named to an owner (LOE landed 7/2).
- **Plan & Design (5/15 → 8/14)** — staged two-go-live timeline; peak-freeze boundary decided; the six invariants and six-step choreography drafted; rollback concept — consumers revert to the prior publish. *Exit bar:* council 7/31; FSD 8/14; freeze boundary signed.

- **Build & Test (Aug → Jan/Apr)** — three mock cutovers against the 0.5% tolerance; runbook tasks authored with owner, duration, predecessor; E2E days; the shadow monitor for the interim copy built and tested. *Exit bar:* mock 3 inside tolerance; E2E green three dates; B + C open = 0.
- **Cutover & Go-Live (January; May 1 → Jul 1)** — executed the runbook: clear negatives, transfer AFS to Uncommitted, scan-and-reserve, zero-then-publish; inbound re-pointed W801 → W901 per shipment in Proship/TMS; triggers armed per interface. *Exit bar:* six invariants held; rollback never fired.
- **Hypercare / Close (Jun → Jul)** — daily issue read; weekly Locus gate read; control-owner handoff; hypercare exit memo; template handed to the next DC. *Exit bar:* < 2 blockers/day sustained → exit week 3 of 4.

Influence and ownership. Mine: the runbook, the invariants, the choreography, the trigger numbers and the go/no-go recommendation. Executed by: platform, BlueYonder, Locus and DC Ops teams, each owning their tasks. QA owned the gate; steering signed the criteria.

> **Designed the process; others own it now.** The runbook format (owner · duration · predecessor), the invariants and the numeric hypercare exit are the template handed to the next DC. **Trade-off put to leadership:** the date versus the bar — a counted go/no-go rather than a feeling, and a second cutover rather than two defect classes in one week.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY

- **$** — modeled: runbook effort 814.75 h × $110 = $89,622; one week of the modeled ≈$1.65M/yr benefit ≈ $31,731/wk → the runbook costs ≈2.8 weeks of what it protected. Not claimed as a saving.
- **#** — 343 tasks / 48,885 task-minutes ≈ 815 h; 61-day window; 836-row issues log, 85.4% closed; monthly new-row arc 271 → 65 → 21 → 14 → 4 (record, from the log).
- **%** — new-row arc −98.5% from June to October; sync trigger < 99% for 4 h; p95 trigger > 2× for 1 h (record).
- **Time** — May 1 → Jul 1; hypercare exit week 3 of 4; peak freeze Oct–Dec untouched (record).
- **Customer** — zero customer-facing incidents through both go-lives; rollback armed twice, never fired (record).
- **Quality** — six invariants held; one irreversible instant identified; Blocker + Critical open = 0 at go/no-go.

L6 LEVEL EVIDENCE — every line is this story's record or labeled model, no new canon numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	A cutover with no agreed stop condition; I defined the invariants, the triggers and the go/no-go bar.
Scope & influence	About a dozen impacted systems, 60+ stakeholders; each task owned by someone who did not report to me.
Execution trade-off + mechanism others own	Two go-lives (a second cutover) versus one (two defect classes in the same week); the runbook format is the mechanism others own.
Impact	Zero customer-facing incidents; two go-lives landed; rollback never needed.
Process improvement	Runbook as owned tasks; irreversible instant named; triggers as numbers; hypercare exit as a number.
Complexity & consensus	Peak freeze, vendor RTL slip, interim two-truth reporting, six invariants across systems.
Root cause at scale	The cutover risk concentrated at one instant — zero-then-publish — so the design put the controls there.

PROBING — FIVE FACETS, THEN THE HARDEST FOLLOW-UPS NEW

THE FIVE FACETS — WHERE EACH ONE LIVES IN THIS STORY

1 · Data analysis. Grain: task × owner × duration × predecessor; SKU × selling location at cutover; issue × severity × day. Cuts: task-hours by day; blockers by day; negatives by SKU. Revealed: the cutover had many tasks and one irreversible instant.

2 · Solution design. Options: (A) one big-bang go-live; (B) two go-lives each carrying one defect class (chosen); (C) a parallel run. A mixes defect classes; C leaves two truths live. B costs a second cutover and buys single-cause diagnosis.

3 · Math & data logic. Σ AFS_800 + Σ AFS_900 conserved; min(AFS_800, AFS_900) = 0 at every instant; triggers: sync < 99% × 4 h → ≈24 events ≈ $714 exposure; p95 > 2× × 1 h; persistence: q^4 vs q.

4 · Implementation. Runbook of 343 tasks; six-step choreography; per-shipment inbound re-pointing; rollback per interface; daily issue read; control-owner handoff. Day-one pace planned in units — 280,000 units, 40 stores, 7 inbound appointments (user anchor, loop packet only) — and a discovery curve of 68 → 160 → 34 issues a week (record, computed from the log).

5 · Probe questions. Below: what made you say go, what did the triggers cost, what's irreversible, why two go-lives, and the three trap drills.

FACET 5 — PROBE QUESTIONS (CHALLENGE Q&A TUNED TO THIS INTERVIEWER)

Infra — what made you say go?

Counted rows: Blocker + Critical at zero, mock 3 inside 0.5%, runbook rehearsed, rollback armed per interface. I would have said no-go on one open Blocker; I never had to.

Infra — what is irreversible and how did you handle it?

Step 4, zero-then-publish: AFS_800 set to zero, then the same AFS published at 900. The reversible steps came first (clear negatives, transfer to Uncommitted, scan-and-reserve) so by step 4 the only open question was the publish.

> **Infra — what do the triggers cost if they are wrong?**
> On illustrative volume ≈595 units/h, 1% unsynced for 4 h is ≈23.8 events ≈ $714 of oversell exposure; a p95 at 120 s instead of 60 s for an hour adds a 60 s staleness window ≈ 9.9 units ≈ $298. Small against the cost of a false rollback, which is why the persistence requirement matters.

> **Infra — why two go-lives?**
> So we never hunted two defect classes in the same week. January was the planning go-live — purchasing and inbound, reserve rules live against demand, the floor untouched; May left warehouse execution as the only class.

> **Infra — what did the interim cost?**
> For four months every report had to declare which system of record it read — the price of two live truths. I would staff the interim reporting workstream on day one, not month three.

BUSINESS IMPACT MODEL — KPI DRIVERS, BASELINE → AFTER

DRIVER	BASELINE	AFTER	$ / EFFECT	BASIS
Runbook	unplanned	343 tasks · 815 h · 61 days	$89,622 effort (modeled)	record / modeled
Irreversible instants	unknown	1 (step 4)	—	record
Rollback triggers	none	2 per interface; never fired	exposure ≈$714 / ≈$297	record / illustrative
New issue rows per month	271 (June)	4 (October)	−98.5%	record
Customer-facing incidents	0 allowed	0 through both go-lives	—	record

THE MATH — FOUR-TABLE DERIVATION (FORMULA → SUBSTITUTION → RESULT) NEW

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Runbook size	`48,885 / 60 = 814.75 h; 48,885 / 343 = 142.5 min per task`	record	≈815 h / 142.5 min avg
2	Window	`May 1 → Jul 1 = 31 + 30 = 61 days; 814.75 / 61 = 13.4 task-hours per day`	record	61 days
3	Irreversible instants	`1 — step 4, zero-then-publish`	record	1
4	Exposure of an unsynced event	`$6 + $4 + $19 + $1 = $30 per oversell`	S1 benchmark	$30
5	Interim state	`two live truths for four months`	record	4 months
6	Arc start	`271 new rows in June (the go-live month)`	record, from the log	271

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Step 1 — clear negatives	`SKU C: AFS_800 = −10 → corrected to 0 (audited); ΣAFS_800 = 560 + 120 + 0 = 680 (was 670)`	illustrative 3-SKU trace; invariant: negatives cleared first	680
2	Step 2 — transfer AFS to Uncommitted	`Σ Uncommitted = 680`	record step	680
3	Step 3 — scan-and-reserve	`reserve the scanned units; no change to Σ`	record step name; effect illustrative	680
4	Step 4 — zero-then-publish	`AFS_800 := 0 for A, B, C; then publish AFS_900 = 560, 120, 0; Σ = 0 + 680 = 680`	one irreversible instant	Σ conserved
5	Double-sellable window avoided	`publish-first would make 680 units sellable on both: 2 × 680 = 1,360 promised on 680`	why zero comes first	never both
6	False-zero window	`≤ 60 s budget; demand in 60 s = 0.165 units/s × 60 = 9.9 units`	100K units/week illustrative	≈9.9 units
7	Asymmetry applied	`undersell 9.9 × $4.75 = $47 vs oversell 9.9 × $30 = $298; ratio 6.3 : 1`	$4.75 = $19 × 25% (illustrative)	6.3 : 1
8	Trigger — sync	`1% × 595.2 u/h = 5.95 events/h × 4 h = 23.8 events × $30 = $714`	595.2 = 100,000/168 (illustrative)	≈$714

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
9	Why persistence	q = 2% healthy per-hour breach: P(4 consecutive) = 0.02^4 = 1.6×10^{-7} vs 0.02 for one hour; over 1,464 windows: 0.00023 vs 29.3 false fires	q illustrative; independence assumed	0.00023 vs 29.3

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	New issue rows per month	271 (June)	4 (271 → 65 → 21 → 14 → 4, October)	record
2	Blocker + Critical open at go/no-go	441 logged	0 open	record
3	SKU sellable on both locations at once	possible in the interim	never — min(AFS_800, AFS_900) = 0	record invariant
4	Rollbacks fired	armed twice	0	record
5	Hypercare exit	—	week 3 of 4 at < 2 blockers/day	record

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Runbook effort	814.75 h × $110 = $89,622	$110/h blended (modeled)	≈$89.6K
2	Weekly benefit at stake	$1.65M / 52 = $31,731	S2's modeled recurring benefit	≈$31.7K/wk
3	Runbook as weeks of benefit	$89,622 / $31,731 = 2.82 weeks	rows 1–2	≈2.8 weeks
4	Sync-trigger exposure	23.8 events × $30 = $714	illustrative volume	≈$714
5	Staleness exposure at the p95 trigger	9.9 units × $30 = $298	60 s extra window	≈$297
6	One week of slip	$1.65M / 52 = $31,731	deferred benefit (modeled)	≈$31.7K

SOLUTION FLOW — THE SYSTEM & DATA MAP

```
RUNBOOK (343 tasks, owner + duration + predecessor, May 1 -> Jul 1)
 Step 1  clear negatives      (AFS Correction, audited)        reversible
 Step 2  transfer AFS -> Uncommitted                           reversible
 Step 3  scan-and-reserve                                      reversible
 Step 4  ZERO AFS_800 -> PUBLISH AFS_900         <== the one irreversible instant
 Step 5-6 (not in the packet - VERIFY)
      |
 per-interface triggers: sync < 99% for 4 h  |  p95 > 2x budget for 1 h
      | fire -> consumers revert to the prior publish
      v
 hypercare: new rows/month 271 -> 65 -> 21 -> 14 -> 4 ; exit when < 2 blockers/day sustained
 inbound dock side: Proship/TMS re-points wh_id W801 -> W901 shipment by shipment
```

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Blended rate	$90 → $73.3K	$110 → $89.6K	$130 → $105.9K
Volume per hour (sync trigger exposure)	300 u/h → $360	595 u/h → $714	1,000 u/h → $1,200
Healthy per-hour breach q	1% → 0.00001 false fires	2% → 0.00023	5% → 0.0092

Runbook as weeks of benefit	—	2.8	4.2 at the low benefit

SPOKEN STATEMENT

> "The cutover was 343 tasks and one irreversible instant. I put every control at that instant — clear the negatives, transfer to uncommitted, scan-and-reserve, then zero the old selling location and publish the new one — so no SKU was ever sellable in two places and the worst case was a sixty-second false zero, which costs about a sixth of a double-sell on S1's benchmarks. The triggers were numbers per interface, and the persistence requirement is why they would not false-fire. I wrote the go/no-go off counted rows; the record is zero customer-facing incidents and a rollback that was armed twice and never needed. The runbook cost about $90,000 of effort at an illustrative rate — under three weeks of the benefit it protected."

IF CHALLENGED

> **“The rollback never fired — how do you know it works?”**
>
> I don’t know it end to end under load, and I will say so. What the record has is that the triggers were armed per interface, the failback concept was consumers revert to the prior publish, and the three mocks ran against the tolerance. The right do-differently is a timed rollback drill in mock three.

> **“Why four hours?”**
>
> Persistence. At an illustrative 2% healthy per-hour breach, four consecutive hours is 1.6×10^{-7} per window; one hour would false-fire about 29 times over the cutover. The assumption is independence — correlated outages break it — so the p95 trigger is the fast path.

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Tell me about a cutover you owned.	Ownership	343 tasks; one irreversible instant; triggers as numbers; go/no-go off counted rows; zero incidents.	Do not claim I executed the tasks.
Tell me about delivering under a tight timeline.	Deliver Results	61 days; peak untouched; two go-lives; a week of slip is ≈$31.7K modeled.	Do not bank the benefit.
Tell me about a time you held a line on quality under schedule pressure.	Have Backbone	No UAT compression; no-go on one open Blocker; escalated the RTL slip the week it surfaced.	Never claim a no-go that did not happen.
How do you decide when to roll back?	Functional — cutover design	Numeric triggers per interface; persistence; revert to prior publish; a timed drill.	Never say it ‘worked in prod’.

BEHAVIORAL PACK — FOUR SEPARATE 90-SECOND STAR ANSWERS, EACH FROM A DIFFERENT MOMENT OF THE STORY NEW

OWNERSHIP · AIQB Q4 **Q1. “Tell me about a time when you made a hard decision to sacrifice short term gain for something that would create long term value for the business.”**

I recommended giving up speed for certainty — two go-lives and a four-month bake — and wrote the go/no-go off counted rows rather than confidence. By the time of the May cutover Blocker plus Critical open was zero, mock three was inside the 0.5% tolerance, the 343-task runbook had been rehearsed, and rollback was armed per interface. I would have called no-go on one open Blocker, and I meant it. The runbook had one irreversible instant, step four, zero-then-publish, and I put every control at that instant: negatives cleared first, AFS transferred to uncommitted, scan-and-reserve, then zero the old selling location and publish the new. When something needed to be decided, it was decided against a number I had written before anyone was tired. The result was zero customer-facing incidents through both go-lives and rollback armed twice, never fired. The interim reporting burden — four months of every report declaring its system of record — was a cost I should have staffed earlier, and I say that too.

Number to land: 343 tasks · 1 irreversible instant · 0 incidents · rollback armed twice, never fired · **Pivot to NACF:** At NACF the owner of a new-FC launch writes the go/no-go off counted rows — doors tested, appointments scheduled, UPH validated — and the stop conditions before the first live trailer. · **Do NOT say:** that I executed the tasks; that the rollback was proven under load.

DELIVER RESULTS · AIQB Q1 **Q2. “Give me an example of a time when you were able to deliver an important project under a tight deadline.”**

The window was 61 days, May 1 to July 1, with the October to December peak freeze behind it — so slipping was not free. I wrote the runbook as 343 owned tasks, about 815 hours, each with a predecessor so the critical path was visible. A week of slip was worth about $31,700 of deferred benefit on S2’s modeled $1.65 million a year; the whole runbook cost about $90,000 of effort, under three weeks of that. So when the Locus RTL slipped three weeks I escalated the week it surfaced and re-slotted rather than letting it sit. Two go-lives landed on their dates, the monthly count of new issue rows fell 271 to 65 to 21 to 14 to 4, and hypercare exited in week three of four at under two blockers a day. The +15% processing efficiency was measured post-stabilization by DC Ops. The date held because every task had an owner and a predecessor.

Number to land: 61 days · 815 h · new rows 271 → 4 a month · exit week 3 of 4 · **Pivot to NACF:** At NACF a new-FC date lives or dies on the same arithmetic — doors, hours, appointments — written as owned tasks. · **Do NOT say:** that the $31.7K is banked; that the $90K runbook cost is a record.

HAVE BACKBONE; DISAGREE AND COMMIT · AIQB Q5 **Q3. “Tell me about a time when you pushed back against a decision that negatively impacted your team.”**

The Locus RTL slipped three weeks, and the easy way to absorb it was to compress UAT. I refused. I escalated the slip the week it surfaced — not when it hurt — re-slotted the plan openly so everyone saw the new dates, and held UAT at its full length; the robotics were retested after the slip. My argument was the bar itself: Blocker plus Critical open had to be zero at go/no-go, and compressing UAT would have moved findings from the test room to the floor. One open Blocker is a no-go; I never had to call it, because the bar was written before the pressure arrived.

Number to land: RTL slipped 3 weeks · UAT not compressed · B + C open = 0 · **Pivot to NACF:** At NACF the same line applies to a launch date — what is the bar, in numbers, that a slipped vendor does not get to lower. · **Do NOT say:** that I overruled steering; the dates were re-slotted openly, not forced.

DIVE DEEP · AIQB Q6 **Q4. "Have you ever created a metric that helped identify a need for a change in your department?"**

I did the arithmetic on the thresholds instead of accepting round numbers. The rollback trigger — sync below 99% for four consecutive hours — sounds arbitrary until you price it: on an illustrative 100,000-unit week, 1% unsynced for four hours is about 24 events, roughly $714 of oversell exposure at $30 each. The four-hour persistence is why it does not false-fire: at an illustrative 2% healthy breach, four consecutive hours is one in six million per window; a single hour would false-fire about 29 times across the cutover. And I traced three SKUs through the irreversible step to prove the invariant: the units across both selling locations sum to the same 680 before and after, and no SKU is sellable on both. The false-zero window costs about a sixth of a double-sell. Detail, not drama.

Number to land: ≈24 events ≈ $714; 0.02^4 vs 0.02; 680 conserved · **Pivot to NACF:** NACF dock and UPH plans run on the same detail — appointment slots and dwell — and I would price every threshold the same way. · **Do NOT say:** that the exposure numbers are measured; they are illustrative on 100K units/week.

SAME STORY, THREE ANGLES — DATA · CONFLICT/INFLUENCE/BACKBONE · FAILURE-LEARNING NEW

DATA ANGLE · DIVE DEEP

"343 tasks, 48,885 minutes, 61 days — and the cutover had one irreversible instant."

Headline metric: 814.75 h · $89.6K · 2.8 weeks of benefit

The runbook arithmetic plus the trigger pricing ($714) and the persistence math show every threshold has a number behind it. Honest limit: volume, rate and q are illustrative.

CONFLICT / INFLUENCE ANGLE · HAVE BACKBONE; DISAGREE AND COMMIT

"When the vendor slipped three weeks, the easy answer was to squeeze UAT. I said no."

Headline metric: RTL +3 weeks; UAT not compressed

Escalated the week it surfaced; re-slotted openly; UAT held at full length; the no-go bar (one open Blocker) was set before the pressure.

FAILURE / LEARNING ANGLE · OWNERSHIP

"For four months every report had to say which system of record it read — and I staffed that workstream in month three."

Headline metric: interim reporting staffed month 3, not day 1

The record's own do-differently: the interim cost was predictable and I treated it as a task, not a workstream. Second honest limit: rollback armed twice, never fired — I cannot prove it under load

confirm whether a timed rollback drill ran in the m

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS, WITH NUMERIC ANSWERS NEW

How do you know the cutover worked because of the runbook and not because the team was good?

I can't separate them, and a good team is part of the design: each task had an owner, duration and predecessor. The measurable thing is the invariants held (Σ AFS conserved, no SKU sellable twice) and the monthly new-row arc 271 → 4.

Say: *"The runbook's job was to make good people's work sequenceable; the evidence is that the invariants held and the monthly new-row arc went 271 to 4 — not that the team was lucky."*

Why not one go-live and save the second cutover?

The second cutover buys single-cause diagnosis: in a one-go-live world every issue triages against two hypotheses. The cost of the second go-live is real and in the record: a deliberate four-month bake running two systems of record, with daily reconciliation (Apple C1). The decision is qualitative — triage time, not fix time, is what a 160-issue week costs, and the issues log confirms that week: 68, then 160, then 34 identified in the weeks of June 9, 16 and 23 (computed from the file).

Say: *"I paid for a second cutover to keep diagnosis univariate; that is a judgment call, and I put the price on the table at steering."*

What would have changed your mind on go?

One open Blocker; mock 3 outside 0.5%; a sync read below 99% in the rehearsal; or a rollback I couldn't describe in a sentence per interface.

Say: *"Any one of four numbers — one open Blocker, mock three over half a percent, sync under 99%, or a rollback I couldn't state per interface."*

20-SECOND VERSION + NACF BRIDGE NEW

20-second version. I owned the Utah DC cutover runbook — 343 tasks, about 815 hours, a 61-day window — with one irreversible instant, zero-then-publish, rollback triggers written as numbers per interface (sync under 99% for four hours; p95 over twice budget for an hour), and a go/no-go off counted rows; zero customer-facing incidents through both go-lives and rollback never needed.

NACF bridge. NACF's new-FC launch has the same irreversible instant — the first live inbound appointment — and I would write it the same way: an owned-task runbook, a numeric go/no-go, and stop conditions before the first trailer. At Sephora the dock-side version was re-pointing each inbound shipment's warehouse ID W801 → W901 in Proship/TMS, shipment by shipment; at NACF the CAP-A 85% door ceiling is the slack that absorbs a re-pointed or late trailer.

U6 — Negative AFS and the AFS Correction screen — detecting an over-committed SKU, root-causing it to one of three seams, and giving every AFS-changing act a screen, a role and an audit row NEW

LPs this story serves here: Dive Deep (primary — decomposing a negative to its cause class) · Ownership (the control-owner map handed off) · Customer Obsession (a negative is a promise we cannot keep) · Insist on the Highest Standards (drift tolerance zero; negatives clean at T+1)
Process family: Deliver / Return — inventory-accuracy control: exception detection, root cause by cause class, control-owner governance

Honesty label. Record: AFS = Basis − PickRes − EcomPick − EcomPack − SNB; negatives cleared first at cutover; Negative AFS clean at T+1 was a go-live exit bar; daily ISM-vs-MB52 drift with tolerance 0 — a non-zero drift is a Sev, not a planning variance; control-owner map: Negative AFS → Inventory Control, Internal Audit and Finance; AFS Correction → ISM app team; the daily drift report → Inventory Control; every AFS-changing act had a screen, a role and an audit row; the register's top three risks — vocabulary drift, feed latency from WMS/OMS/POS, override abuse on AFS-changing screens — are my three cause classes. **Illustrative:** the −10 SKU, its 5/3/2 split, $30 per incident, the σ = 10 sanity check. Record-from-docs (issues-log file, Comments column): row ID 716 and row ID 818 — the only two of 836 rows that name AFS. I defined the screens, owners and cause classes; ISM app and platform teams built them; the control owners run them.

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH

Dive Deep. A negative AFS is a symptom; I decomposed it into three cause classes — event cardinality, feed latency, override — each with a different fix and a different owner.

Ownership. Every AFS-changing act had a screen, a role and an audit row before I stepped back; the control owners ran the Negative AFS report without me.

Customer Obsession. A negative AFS is units already promised that the floor cannot back; I treated it as a customer defect with a clock, not a variance.

Insist on the Highest Standards. Drift tolerance was zero — a non-zero drift is a Sev — and the exit bar was zero SKUs of drift on consecutive days, with negatives clean at T+1.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. Once Sephora's Utah DC became one comingled pool with one published AFS per node per channel, there was one new failure mode: a SKU whose committed buckets exceed what the floor can back — a negative AFS, units we have already promised and cannot ship. **Task.** Own how that is detected, root-caused and fixed, and who is allowed to change an AFS at all. **Action.** I defined the screens and the control-owner map before go-live: the Negative AFS report to Inventory Control, Internal Audit and Finance; the AFS Correction screen to the ISM app team; the daily drift report, ISM-vs-MB52, to Inventory Control, with tolerance zero — a non-zero drift is a Sev, not a planning variance. Every AFS-changing act had a screen, a role and an audit row. Root cause went by cause class — the register's top three: event cardinality, feed latency, override — so a worked SKU at minus ten decomposes into a duplicate event, a lagging WMS feed and a manual override, each with its own owner. The asymmetry behind it: oversell costs about $30 and an undersold unit about $4.75, a 6.3-to-1 ratio, so the published number sits near the 14th percentile of true availability — and the lower-of-two basis gets within a unit of that. **Result.** Primary metric: customer-facing oversell incidents zero through both go-lives; negatives clean at T+1 at cutover; drift at zero SKUs on consecutive days at hypercare exit; the control owners running the report without me.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — A comingled pool publishes one AFS per node per channel and the OMS reads it, never computes it. When committed buckets exceed Basis, AFS goes negative: units promised that the floor cannot back. Before ISM, two books were reconciled by hand — about 4 FTE — and a negative surfaced as an order that could not ship.

T — Design detection, cause-class root-causing and ownership for exceptions that change AFS — so that a negative is found, explained, fixed and audited by the people who own the consequence, not by me.

Baselines on the table: ≈4 FTE reconciling two books by hand · drift unmeasured → tolerance 0 · negatives clean at T+1 as a go-live bar · the register's top-three risks (vocabulary drift, feed latency, override abuse) each with a trigger, a mitigation and an owner — mine was drift.

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery (3/29 → 4/30)** — bucket inventory with one owner per bucket; where in the old world negatives appeared and who chased them; sessions closed 4/30. *Exit bar:* every bucket owned by one system; open questions dated.
- **Plan & Design (5/15 → 8/14)** — wrote AFS = Basis − buckets; asymmetry (oversell customer defect / undersell planning variance); drift tolerance 0; screens and roles; the three cause classes from the risk register. *Exit bar:* FSD signed 8/14; every AFS-changing act has a

screen and a role.

- **Build & Test (Aug → Jan/Apr)** — matrix cells for negatives, replays and overrides (U1); AFS Correction audit-row assertions; SIT contract defects closed before UAT. *Exit bar:* Blocker + Critical open = 0; E2E days dated.
- **Cutover & Go-Live (January; May 1 → Jul 1)** — step 1 of the May choreography: clear negatives first; Negative AFS clean at T+1; the screens live with control owners assigned. *Exit bar:* negatives clean at T+1; no SKU with two published AFS values.
- **Hypercare / Close (Jun → Jul)** — daily drift report; Negative AFS / AFS Correction audit review; control-owner handoff; exit into the monthly release train. *Exit bar:* drift = 0 SKUs on consecutive days; owners running the report without me.

Influence and ownership. Mine: the cause classes, the screens' definitions, the owner map, the tolerance. ISM app and platform teams built the screens; Inventory Control, Internal Audit and Finance run Negative AFS; the ISM app team runs AFS Correction.

> **Designed the process; others own it now.** Control owners and the monthly release train own the screens now. **Trade-off put to leadership:** visible undersell and a zero-tolerance drift — more investigations — against oversell as a customer defect; I accepted the investigations.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY

- **$** — modeled from S1: reconciliation 4 → 1 FTE = 3 × $110K = $330K/yr; baseline oversell exposure 30,000/365 = 82.2 incidents/day × $30 = $2,466/day on illustrative orders. Not claimed as savings; the record movement is incidents → zero.
- **#** — negatives clean at T+1 at cutover; drift = 0 SKUs on consecutive days; 3 cause classes; 3 control-owner orgs + the ISM app team (record).
- **%** — asymmetry 1 : 6.3; critical ratio 13.7% (modeled on S1's benchmark).
- **Time** — T+1 at cutover; hypercare exit week 3 of 4; FSD signed 8/14 (record).
- **Customer** — customer-facing oversell incidents zero through both go-lives (record).
- **Quality** — every AFS-changing act has a screen, a role and an audit row; drift tolerance 0 (record design).

L6 LEVEL EVIDENCE — every line is this story's record or labeled model, no new canon numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	Nobody owned exceptions to the published number; I defined cause classes, owners and tolerances.
Scope & influence	Inventory Control, Internal Audit, Finance and the ISM app team — four groups that did not report to me — own the screens.
Execution trade-off + mechanism others own	Zero-tolerance drift (more investigations) against ambiguity; the mechanism others own: the screens and the audit rows.
Impact	Oversell incidents zero through both go-lives; reconciliation moved from argument to a daily report.
Process improvement	Exceptions have a class, an owner, a screen and an audit row; the same map applies to any new node or channel.
Complexity & consensus	Three orgs signed the definitions; four groups run the controls.
Root cause at scale	Negatives collapse into three seams (cardinality, latency, override); the fix is at the seam, not the SKU.

PROBING — FIVE FACETS, THEN THE HARDEST FOLLOW-UPS NEW

THE FIVE FACETS — WHERE EACH ONE LIVES IN THIS STORY

1 · Data analysis. Grain: SKU × node × channel × bucket × time. Data: ISM buckets, MB52 snapshot, the audit rows — and, for the legacy-side evidence, the 836-row WMS/Locus issues log: a keyword search of its five text columns finds only two rows that name AFS. Row ID 716 (Critical, IC): 'Dept 96 has 1800 SKUs. 400 are − AFS in MCS and 0 in BY' — 22.2% of that department's SKUs negative in the legacy book and none in the WMS. Row ID 818 (Critical): inventory holds validated moving units 'from AFS to Merch Res after about 10min' — a latency datum inside the ≤15-minute feed budget. Cuts: negatives by cause class. Revealed: the WMS defect book is nearly silent on AFS, so exceptions to the published number needed their own controls in ISM/S/4.

2 · Solution design. Options: (A) reconcile by hand (4 FTE); (B) a daily report with no owners; (C) a screen + role + audit row per AFS-changing act with a cause class (chosen). A and B leave exceptions unowned.

3 · Math & data logic. AFS = 25 − (12 + 10 + 8 + 5) = −10; critical ratio = $4.75 ÷ ($4.75 + $30) = 13.7%; z = -1.10; buffer = 1.10 × σ(10) = 11.0; lower-of-two sits 10 below the mean of the books (990 → 980); drift = 957 − 957 = 0.

4 · Implementation. Screens and owners at design; clear negatives first at cutover; T+1; daily drift at hypercare; handoff and exit memo. Risks: vocabulary drift, feed latency, override abuse.

5 · Probe questions. Below: how do you root-cause a negative, why tolerance zero, what the screen cannot see, who owns what, and the three trap drills.

FACET 5 — PROBE QUESTIONS (CHALLENGE Q&A TUNED TO THIS INTERVIEWER)

Infra — a SKU shows −10. What do you do?

Decompose by cause class. Cardinality: an event in two buckets (a duplicate SNB) — fix the event, replay is a no-op, add a matrix cell. Latency: a WMS adjustment still inside the ≤15-minute feed plus under-5-minute consumer lag — wait and re-read. Override: a manual AFS change — check role and audit row. On the illustrative split 5/3/2 the first fix takes the −10 to −5.

Infra — why drift tolerance of zero?

Because the books should agree and a difference means one of them is wrong; a non-zero drift is a Sev, not a planning variance. It also made the hypercare exit crisp: zero SKUs of drift on consecutive days. If I had to set a non-zero tolerance I would price it: each unit is up to $30.

Infra — what can the Negative AFS screen not see?

Undersell. It is a one-sided detector: a SKU showing less than the floor could sell never goes negative. The asymmetry makes that deliberate, but it means a wrong rule that starves a channel (my first in-transit rule, master S4) is invisible to it.

Infra — who owns what?

Negative AFS: Inventory Control, Internal Audit and Finance. AFS Correction: the ISM app team. The daily drift report: Inventory Control. Every AFS-changing act has a screen, a role and an audit row; override abuse was the register's third risk.

Infra — why is the lower-of-two the right buffer?

Sanity check, not a derivation: a critical ratio of 13.7% puts the published number about 1.10σ under the mean; if the two books' half-gap (10) is one σ, that is ≈11.0 units — and min(1,000, 980) sits 10 under the books' mean of 990.

BUSINESS IMPACT MODEL — KPI DRIVERS, BASELINE → AFTER

DRIVER	BASELINE	AFTER	$ / EFFECT	BASIS
Exception ownership	unowned; 4 FTE by hand	screen + role + audit row; ≈1 FTE reading the drift report	≈$0.33M/yr (S1 modeled)	modeled
Drift (ISM vs MB52)	unmeasured	0 SKUs on consecutive days	tolerance 0	record
Negatives at cutover	present	clean at T+1	—	record
Oversell incidents	recurring	zero through two go-lives	baseline ≈$2,466/day exposure (illustrative)	record / illustrative
Asymmetry	implicit	1 : 6.3 (explicit)	critical ratio 13.7%	modeled

THE MATH — FOUR-TABLE DERIVATION (FORMULA → SUBSTITUTION → RESULT) NEW

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	A negative SKU	`Basis = min(30, 25) = 25; buckets = 12 + 10 + 8 + 5 = 35; AFS = 25 − 35 = −10`	illustrative SKU	−10
2	Exposure	`10 × $30 = $300`	S1 all-in cost per incident (benchmark)	$300
3	Cost of an oversell vs an undersell	`oversell $30; undersell = $19 × 25% = $4.75; ratio = 6.3`	$19 margin; 25% not recovered (illustrative)	6.3 : 1
4	Baseline oversell rate	`30,000,000 × 0.10% / 365 = 82.2/day × $30 = $2,466/day`	S1 illustrative orders; benchmark rate	≈$2.5K/day
5	Reconciliation burden	`≈4 FTE by hand`	record baseline	≈4 FTE
6	Where the AFS evidence sits in the log	`2 of 836 rows name AFS (0.24%); ID 716: 400 ÷ 1,800 = 22.2% of Dept 96 SKUs negative in MCS, 0 in BY`	issues-log file, Comments column (record-from-docs)	22.2%

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Cause class — cardinality	`duplicate SNB event: SNB 5 → 0; AFS = 25 − (35 − 5) = −5`	illustrative 5 of the 10	−10 → −5
2	Cause class — latency	`WMS adjustment +3 arrives inside the 15-min feed: Basis = 28; AFS = 28 − 30 = −2`	illustrative 3 of the 10	−5 → −2

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE

Oversell rate	0.05% → $1.2K/day	0.10% → $2.5K/day	0.25% → $6.2K/day
Reconciliation FTE released	2 × $95K = $0.19M	3 × $110K = $0.33M	4 × $130K = $0.52M
Cause-class split (illustrative)	1 / 1 / 8	5 / 3 / 2	8 / 1 / 1

SPOKEN STATEMENT

> "A negative AFS is units we have already promised and the floor cannot back. I did not treat it as one thing: it decomposes into three seams — an event that landed in two buckets, a feed that has not caught up, and a manual override — and each has a different fix and a different owner. Inventory Control, Internal Audit and Finance run the Negative AFS report; the ISM app team runs the AFS Correction screen; every AFS-changing act has a screen, a role and an audit row. The drift tolerance is zero because a difference means one book is wrong. The record is negatives clean at T+1, drift at zero on consecutive days at hypercare exit, and zero customer-facing oversell incidents through both go-lives; the dollar view is an asymmetry — about six to one — on benchmark inputs."

IF CHALLENGED

"The 5/3/2 split is made up."

It is illustrative, tagged, and I would not quote it. What is record is the three cause classes — they are the register's top three risks — and the owner for each. The real split is a pull from the audit rows.

"How do you know the controls — not the matrix — kept incidents at zero?"

I can't isolate them. The controls and the matrix are two halves: the matrix proves the events are mapped; the screens catch what the mapping did not. The record is the combination: zero incidents, drift at zero, negatives clean.

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Tell me about a time you found the root cause of a recurring issue.	Dive Deep	A negative decomposes into cardinality / latency / override; fix at the seam.	Never quote the 5/3/2 split as measured.
Tell me about a time you built something that others now own.	Ownership	Screens, roles, audit rows; control-owner map; they ran it without me.	Do not claim I built the screens.
Tell me about a time you put the customer ahead of an internal metric.	Customer Obsession	Visible undersell accepted so oversell is zero by construction; 1 : 6.3.	Do not claim the dollars as saved.
What does a high standard look like in inventory accuracy?	Insist on the Highest Standards	Drift tolerance 0; negatives clean at T+1; zero SKUs on consecutive days.	Do not call 0 tolerance easy.

BEHAVIORAL PACK — FOUR SEPARATE 90-SECOND STAR ANSWERS, EACH FROM A DIFFERENT MOMENT OF THE STORY NEW

DIVE DEEP · AIQB Q2 **Q1. "Tell me about a situation that required you to dig deep to get to the root cause."**

The recurring problem was a negative available-to-sell — units promised that the floor could not back — and the first instinct is to fix the SKU. I looked at what a negative actually is: committed buckets exceeding the supply basis. Take a worked SKU with a basis of 25 and 35 units committed: minus ten. I decomposed it into three cause classes — the register's top three: an event that landed in two buckets, a feed that had not caught up, and a manual override. A duplicate event in the shipped-not-billed bucket takes the minus ten to minus five; a warehouse adjustment still inside the fifteen-minute feed takes it to minus two; an unauthorized override, removed through the AFS Correction screen with a role and an audit row, takes it to zero. Each cause class has a different fix and a different owner, so the fix is at the seam, not the SKU. That is why the matrix has a cell for each, and why the control owners had a cause class to write on every audit row.

Number to land: −10 → −5 → −2 → 0 (illustrative); 3 cause classes · **Pivot to NACF:** At NACF, a negative-available ASIN decomposes the same way — a double receive scan, dock-to-stock lag, a manual adjustment — and I would ask which seam first. · **Do NOT say:** that the 5/3/2 split is measured; that I built the screens.

OWNERSHIP · AIQB Q5 **Q2. "Describe a time when you had to transition a project you owned to a new owner."**

I did not finish the program until the exceptions had owners who did not need me. Before go-live I mapped every AFS-changing act to a screen, a role and an audit row, and every exception report to an owner: the Negative AFS report to Inventory Control, Internal Audit and Finance; the AFS Correction screen to the ISM app team; the daily ISM-versus-MB52 drift report to Inventory Control. In hypercare the test was whether the control owners ran the report without me — part of the exit bar, along with drift at zero SKUs on consecutive days and blockers under two a day. Then the design entered the monthly release train, so a new node or channel is a matrix row and an owner row, not a project. I measure ownership by whether the process survived my leaving.

Number to land: 3 owner orgs + ISM app team; drift 0 on consecutive days · **Pivot to NACF:** At NACF I would hand a launch's exception reports to named owners with a screen, a role and an audit row before the first live trailer. · **Do NOT say:** that I run the screens now; the control owners do.

CUSTOMER OBSESSION · AIQB Q8 **Q3. "Tell me about a time when you had to balance the needs of the customer with the needs of the business."**

The convenient metric was a clean-looking available number; the customer's interest was a promise we could keep. A negative AFS is a customer we have already told yes. So the policy is an asymmetry: an oversell is a customer defect, about thirty dollars on benchmark inputs; an undersell is a planning variance, about five. That is roughly six to one, and the asymmetry decides the design — the supply basis is the lower of the two books, so the published number sits conservatively under the truth. The price is visible undersell: some sellable stock shows as unavailable, and Inventory Control chases it. I accepted that on purpose. A sanity check supports it: a six-to-one asymmetry puts the right published number about one standard deviation below the mean, and the lower-of-two sits within about a unit of that on the worked SKU. The record is customer-facing oversell incidents going to zero through both go-lives.

Number to land: 1 : 6.3 asymmetry; critical ratio 13.7%; incidents → zero · **Pivot to NACF:** At NACF the promise date on an order is the same commitment — I would hold a conservative buffer against a missed date on the same arithmetic. · **Do NOT say:** that undersell is free; that 6.3 is measured — it rests on S1's benchmark and a 25% assumption.

INSIST ON THE HIGHEST STANDARDS · AIQB Q1 **Q4. "Describe a time when you refused to compromise your standards around quality/customer service, etc."**

I set the drift tolerance at zero, and people reasonably asked whether that was realistic. The daily check is ISM's copy of S/4 available against the MB52 snapshot, and a non-zero drift is a Sev, not a planning variance, because two books that should agree and don't mean one of them is wrong — and you do not know which one a customer will meet. The cost is more investigations — the trade I accepted. I made the standard checkable: negatives clean at T+1 at cutover, drift zero SKUs on consecutive days as the hypercare exit, and blockers under two a day. It held because the exit was a number nobody could negotiate. The thing I would say honestly is that zero tolerance is a posture, not a guarantee — it is only as good as the cause class written on each audit row.

Number to land: drift tolerance 0; exit: 0 SKUs on consecutive days · **Pivot to NACF:** At NACF I would set the same kind of zero-tolerance reconciliation on dock-received versus system-available counts, with a number for the exit. · **Do NOT say:** that zero tolerance is easy or free; that it guarantees correctness.

SAME STORY, THREE ANGLES — DATA · CONFLICT/INFLUENCE/BACKBONE · FAILURE-LEARNING NEW

DATA ANGLE · DIVE DEEP

"A negative AFS decomposes into three seams — cardinality, latency, override."

Headline metric: −10 → −5 → −2 → 0 (illustrative)

Cause class decides the fix and the owner; a real log row shows the shape — Dept 96, 400 of 1,800 SKUs negative in the legacy book and zero in the WMS (22.2%) — and a hold feed validated at about 10 minutes against a ≤15-minute budget. Honest limit: the split is illustrative until audit rows are pulled.

CONFLICT / INFLUENCE ANGLE · OWNERSHIP

"Four groups that did not report to me had to own the exception screens before I stepped back."

Headline metric: 3 owner orgs + the ISM app team

The map was in the FSD signed by three orgs (user anchor, master S1); hypercare tested whether the control owners ran the report without me. Influence: a screen, a role and an audit row per act — not a meeting.

FAILURE / LEARNING ANGLE · INSIST ON THE HIGHEST STANDARDS

"'Clean' meant zero negatives — and zero can be reached by an override."

Headline metric: negatives clean at T+1 ≠ cause removed

The exit bar measured the symptom; override abuse was the register's third risk. Do differently: a clean requires a cause class on the audit row, not just a zero.

confirm whether cause class was recorded on au

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS, WITH NUMERIC ANSWERS NEW

How do you know the Negative AFS screen is why incidents went to zero?

I can't isolate it. The matrix proves the events are mapped; the screens catch what the mapping missed; drift at zero is the check that books agree. The record is the combination.

Say: *"I can't separate the screens from the matrix — I can tell you the three checks each caught a different class, and that the combination went to zero incidents."*

Zero-tolerance drift isn't realistic — what is the false-positive cost?

Every difference is investigated, so the cost is investigator hours; the benefit is no unexplained difference between books. A non-zero tolerance would price each unit at up to $30 of exposure; the exit bar made zero crisp.

Say: *"A zero tolerance costs investigation time, and I chose it because an unexplained difference between books is a customer promise I cannot see."*

What can your detector not see?

Undersell — a one-sided detector. A wrong rule that starves a channel never goes negative; the asymmetry makes that deliberate but unusual undersell needs a separate watch — which is what I would add.

Say: *"The Negative AFS screen is blind to undersell by design; the missing control is a watch on unusual undersell, and I would add it."*

20-SECOND VERSION + NACF BRIDGE NEW

20-second version. At the Utah DC I owned exception control for the published AFS: a negative AFS decomposes into three cause classes — duplicate event, feed latency, override — each with an owner, every AFS-changing act has a screen, a role and an audit row, and drift tolerance is zero; negatives were clean at T+1, drift zero on consecutive days, and customer-facing oversell went to zero through both go-lives.

NACF bridge. NACF's equivalent is an ASIN whose committed units exceed what the building can back — a double receive scan, dock-to-stock lag (the dwell side of CAP-D) or a manual adjustment. I would stand up the same map — cause class, owner, screen, role, audit row — and a zero-tolerance reconciliation between dock-received and system-available counts before an FC ramps.

U7 — The 836-row issues log as the building's readiness instrument — severity-first reading, and the 42 rows where the dock, the floor, the power and the footprint were the problem NEW

LPs this story serves here: Dive Deep (primary — three cuts of one book: severity, flow, month) · Insist on the Highest Standards (one grammar; a visible deferral over a buried blocker) · Ownership (rows with no system owner: conveyor, aisle 45, power, guardrails) · Earn Trust (the worst number in the room was mine to say out loud)
Process family: Plan / Execute — program readiness measurement: one log, one grammar, severity-first triage, and the physical-node slice of the defect book

Honesty label. Record-from-docs, computed with pandas from *UDC_Consolidated_Issues_Log_for_BY_WMS-Locus - Copy* (sheet 1; 836 rows × 19 columns; an .xlsx container with a .CSV extension): status, priority, category, type, operation, functional area, owner and date counts are exact. Where I cut a free-text field (Operation; Functional Area) I say which labels I counted. **Limits I will state before I am asked:** the file has no close-date column, so I cannot compute time-to-close or reconstruct what was open at go/no-go from it; it is a late snapshot (last row 2025-10-01); the building slice is my own label grouping. The ACL request-row counts (Dev 310 · QA 255 · Perf 200 · Prod 221) are record from my Apple workbook (C2), not recomputed. Dollar figures in Table 4 are **modeled/illustrative** (30 min a row; $110/h blended, as S5/U5) and are not claimed as savings.

LEADERSHIP PRINCIPLES CARRIED — ONE-LINE PROOF EACH

Dive Deep. I read one 836-row book three ways — severity, flow, month — and the three cuts said different things: Blockers and Criticals closed at 99.4% and 97.1% against 60.0% for Lows; Dotcom was the most severe flow; June was a spike with a 0.35 monthly decay.

Insist on the Highest Standards. One log, one grammar, no side lists; a parking-lot status meant 'decided not now' in writing with an owner — never silently deleted — and the weekly review read Blocker and Critical rows first.

Ownership. 17 of the 42 building rows (conveyor, aisle 45, Locus power, guardrails, chargers) sat with Operations, Engineering or Maintenance — not IT; they went into the same log with a name and a date.

Earn Trust. Any VP could open the log any Monday and see what the team saw; the worst number in the room was mine to say out loud, including the 271-row June spike.

60-SECOND BUSINESS-FIRST PITCH — STOP ON THE PRIMARY METRIC

Situation. The Sephora Utah DC conversion ran about thirty build tracks and sixty-plus stakeholders over about a dozen impacted systems; status by opinion would have drowned it. **Task.** Build the instrument that told us whether the building was ready — before cutover week, not during it. **Action.** One consolidated issues log with one grammar — status, priority, operation, functional area, owner on every row — read Blocker and Critical first at a weekly two-block review, with a parking-lot status for 'decided not now' and one coupled build plan beside it. **Result.** 836 rows; 714 closed — 85.4% — and 98.0% of the 441 Blockers and Criticals; the June go-live spike of 271 rows burned down 65, 21, 14, 4; and the 42 rows where the building itself was the problem — dock, appointments, conveyor, aisle 45, Locus power, footprint — were 92.9% closed with none of the open three a Blocker or Critical. Zero customer-facing incidents through both go-lives.

SITUATION / TASK — THE BUSINESS PROCESS PROBLEM, SCOPE, SCALE, BASELINES

S — About thirty build tracks, sixty-plus stakeholders, about a dozen impacted systems and a building that kept shipping. The risk I was asked to instrument was go-live readiness: defect burn-down, track completion, cutover preparedness. Issues arrived from IT, DC Ops, Engineering, Maintenance and the robotics vendor, in different vocabularies, with no shared priority scale.

T — Make a surprise show up in a Monday review, not in cutover week: one log, one build plan, one runbook — three views of the same dataset — and a way to read the book that put the dangerous rows first.

The book as it stands (computed): 836 rows · 714 closed (85.4%) · 122 not closed, of which 112 carry an open status and 10 have a blank status · Blocker 164 + Critical 277 = 441 (52.8% of the book) · bugs are only 115 rows (13.8%) — the rest are requirements, actions, questions and parked decisions: a work-triage system, not a defect list.

ACTION — THE PROCESS / OPERATING-MODEL REDESIGN, IN GATED PHASES

- **Discovery (3/29 → 4/30)** — agreed the grammar before the first real row: one status ladder (A open → F closed), one priority scale (0 Blocker → 4 Low), operation, functional area and owner on every row; one owner per row. *Exit bar:* grammar signed by IT and DC Ops; no side lists.
- **Plan & Design (5/15 → 8/14)** — decomposed the build plan into about thirty tracks, holiday freeze and critical path visible; physical-node work (conveyor, aisle 45 relabel, guardrails, footprint defaults) entered the log with a named owner and a date rather than living in a facilities thread. *Exit bar:* every track mapped to an E2E gate; building rows owned.
- **Build & Test (Aug → Jan/Apr)** — weekly two-block review (30 min IT, 30 min business) reading Blocker and Critical first; monthly arc watched — about 90 rows in each of February and March from the January bake plus Locus physical testing; Locus-side rows held to 86

(10.3%). *Exit bar:* every red row has a name and a date.

- **Cutover & Go-Live (January; May 1 → Jul 1)** — the log as the readiness gate: both go-lives read burn-down curves, not confidence; network ACL request workbooks per environment as the access gate (Dev 310 · QA 255 · Perf 200 · Prod 221 rows). *Exit bar:* Blocker + Critical bar from the go/no-go; access gate closed per environment.
- **Hypercare / Close (Jun → Oct)** — the 271-row June spike read as healing: 65 → 21 → 14 → 4; the open tail stayed visible and owned. *Exit bar:* decay, not plateau; every open row owned.

Influence and ownership. Mine: the grammar, the weekly read order, the parking-lot rule, the coupling of log, plan and runbook, and the readiness call off counted rows. Sephora IT/WMS (342 rows), Operations (111), Engineering/Maintenance and Locus (86) owned and closed their rows.

> **Designed the process; others own it now.** The log, the plan and the runbook are one dataset in three views, so the next program inherits an instrument, not a habit. **Trade-off put to leadership:** attention — the parking-lot status made deferral explicit so the Blocker-and-Critical half of the book got the room's time.

RESULTS — $ · # · % · TIME · CUSTOMER · QUALITY

- **$** — modeled, not claimed: triaging 836 rows at 30 minutes each ≈ 418 h × $110 = $45,980 ≈ 1.45 weeks of the modeled ≈$31,731/week benefit — the log pays back if it prevents about a week and a half of slip.
- **#** — 836 rows; 714 closed; 441 Blocker + Critical, 432 closed; June spike 271 → 4; building slice 42 rows, 39 closed (computed from the file).
- **%** — 85.4% closed overall; 98.0% of Blocker + Critical closed; closure falls with severity — 99.4%, 97.1%, 75.4%, 69.7%, 60.0% — the read order showed in the curve.
- **Time** — fifteen months discovery through go-live; June spike decay ≈0.35 per month, half-life ≈20 days.
- **Customer** — zero customer-facing incidents through both go-lives (record).
- **Quality** — one grammar, no side lists; deferral explicit; every red row with a name and a date.

L6 LEVEL EVIDENCE — every line is this story's record or labeled model, no new canon numbers

L6 DIMENSION	EVIDENCE IN THIS STORY
Ambiguity	Nobody owned 'ready'; I defined it as counted rows in one log read in a fixed order.
Scope & influence	Sixty-plus stakeholders; IT, Operations, Engineering, Maintenance and the robotics vendor all wrote to the same log — none reported to me.
Execution trade-off + mechanism others own	Attention to Blocker and Critical over a flat read of 836 rows; the mechanism others own: the log grammar and the Monday review.
Impact	Both go-lives read readiness from rows; 432 of 441 Blockers and Criticals closed.
Process improvement	Log, plan and runbook as one dataset in three views; deferral made explicit.
Complexity & consensus	Different vocabularies reduced to five fields; one scale.
Root cause at scale	The monthly shape — ramp, spike, decay — separates a healing cutover from a design problem.

PROBING — FIVE FACETS, THEN THE HARDEST FOLLOW-UPS NEW

THE FIVE FACETS — WHERE EACH ONE LIVES IN THIS STORY

1 · Data analysis. Grain: one row per issue; 19 columns. Joins: none — the discipline was one table. Cuts: severity × status (closure gradient); operation (five flows by exact label: 675 of 836 rows, 161 free-text or blank); month; owner; functional area (dock and building labels). Revealed: closure rates fall monotonically with severity; Dotcom was the most severe flow (64.5% Blocker + Critical); the June spike was 88.2% Go-Live category and decayed fast; the building slice ran more severe than the book (64.3% vs 52.8%) but z = 1.50 — directional, not proven.

2 · Solution design. Options: (A) status by opinion in decks; (B) one tool per track; (C) one log with one grammar, coupled to one build plan and one runbook (chosen). A and B make two rows describe one issue and the counts lie; C makes the count the gate.

3 · Math & data logic. Closure = closed ÷ rows by severity; Blocker + Critical share = 441 ÷ 836 = 52.8%; decay r = (4 ÷ 271)^(1/4) = 0.349, half-life = ln 2 ÷ −ln r = 0.66 months ≈ 20 days; building-slice z = (0.643 − 0.528) ÷ √(0.528 × 0.472 ÷ 42) = 1.50.

4 · Implementation. Five gated phases; the log, the build plan (~30 tracks) and the cutover runbook (343 tasks) as three views; ACL request workbooks per environment as the access gate; weekly two-block review. Risks: duplicate rows, free-text drift, priority inflation.

5 · Probe questions. Below: is 836 a defect fire, how do you know the log is honest, what does the monthly shape tell you, what is in the building slice, and the three trap drills.

FACET 5 — PROBE QUESTIONS (CHALLENGE Q&A TUNED TO THIS INTERVIEWER)

Infra — 836 issues. Isn't that a defect fire?

No — the log proves it. Bugs are 115 rows, 13.8%; the rest are requirements (159), action items, questions (23) and parked decisions. It was the program's work-triage system. What I do read as a risk signal is that 52.8% of the book is Blocker or Critical — and then the closure gradient: 99.4% of Blockers closed against 60.0% of Lows. If everything had been priority one, the curve would be flat; it is not.

Infra — what did the log say about the physical building?

Forty-two rows — 5.0% of the book — carried dock and appointment flow (23) or floor, power and footprint (19): TMS appointments with no POs attached in training (Blocker), retail pallet-build positions not available (Critical), ‘Facilities team remove half of conveyor’ (Critical), remove the west side of aisle 45 and relabel (Critical), Locus IDF temporary power until January 6 (Blocker), remove the yellow guardrail between retail and dotcom (Blocker), update large and standard footprint per SKU with large as the default (Blocker). 27 of the 42 were Blocker or Critical — 64.3% — and 39 closed; the three open were not B+C.

Infra — what does the June spike tell you?

271 rows in one month — 32.4% of the book — 239 of them Go-Live category. Then 65, 21, 14, 4: each month retained about a third of the last, r = 0.35, half-life about 20 days. A spike with fast decay is a healthy cutover; one that plateaus is a design problem. I would have wanted that picture on the wall from the first hundred rows.

Infra — how do you know the log is honest?

One row per issue, one grammar, a weekly read where the worst number was mine to say, a dedupe step in the rhythm — two rows for one issue and the counts lie — and ‘parking lot’ meaning decided-not-now in writing. The file does not carry close dates, so I will not claim a time-to-close from it.

Infra — why were Locus rows only a tenth of the book?

86 rows — 10.3% — because the robotics workstream had its own rhythm and owner, and the 98% gate with the throttle caught the zone-logic problem in week two instead of the floor. They were severe — 65 of 86 Blocker or Critical, 75.6% — and every one closed.

BUSINESS IMPACT MODEL — KPI DRIVERS, BASELINE → AFTER

DRIVER	BASELINE	AFTER	$ / EFFECT	BASIS
Readiness signal	status by opinion	836 counted rows, one grammar	decision on rows, not confidence	record
Blocker + Critical	441 identified	432 closed; 9 open	98.0% closed	record-from-docs (computed)
Go-live spike	271 rows in June	65 → 21 → 14 → 4	−98.5% by October	record-from-docs (computed)
Building slice (dock + floor)	42 rows; 27 Blocker + Critical	39 closed; 3 open, 0 B+C	92.9% closed	record-from-docs (computed)
Triage effort	unmeasured	≈418 h	≈$45,980 (modeled)	modeled

THE MATH — FOUR-TABLE DERIVATION (FORMULA → SUBSTITUTION → RESULT) NEW

Table 1 — before: the problem in numbers.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	The book	`836 rows; dated 830; 6 undated; 2024-03-17 → 2025-10-01; 824 of the dated rows are July 2024 or later`	issues-log file, ‘Date Id’d’	836
2	Severity	`164 + 277 = 441; 441 ÷ 836 = 52.8%`	Priority column	52.8% Blocker + Critical
3	Peak month	`271 ÷ 836 = 32.4% of the book in June 2025`	Date Id’d	32.4%
4	How much of the free-text Operation field fits five flows	`238 + 172 + 113 + 90 + 62 = 675; 675 ÷ 836 = 80.7%; remaining 161`	exact labels after trim and lowercase; IC includes ‘inventory control’	80.7%
5	The building slice	`dock/appointment labels 23 + floor/space labels 19 = 42; 42 ÷ 836 = 5.0%`	Functional Area labels listed in the flow box	42 rows

Table 2 — the fix: step by step, values substituted.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Closure gradient — Blocker	`163 ÷ 164`	closed ÷ rows	99.4%
2	Closure gradient — Critical / High	`269 ÷ 277 = 97.1%; 190 ÷ 252 = 75.4%`	closed ÷ rows	97.1% / 75.4%
3	Closure gradient — Medium / Low	`69 ÷ 99 = 69.7%; 21 ÷ 35 = 60.0%`	closed ÷ rows	69.7% / 60.0%

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
4	Severity by flow	`Dotcom 40/62 = 64.5% · Retail 100/172 = 58.1% · Inbound 58/113 = 51.3% · Outbound 119/238 = 50.0% · IC 39/90 = 43.3%`	B+C ÷ rows per flow	Dotcom highest
5	Spike decay	`r = (4 ÷ 271)^(1/4) = 0.349; half-life = ln 2 ÷ −ln(0.349) = 0.66 mo`	geometric mean of 65/271, 21/65, 14/21, 4/14	≈20 days
6	Building slice vs the book	`27 ÷ 42 = 64.3% vs 52.8%; SE = √(0.528 × 0.472 ÷ 42) = 0.0770; z = 1.50`	one-sample proportion z (normal approximation)	z = 1.50 — directional

Table 3 — after: the metric, before → after.

STEP	METRIC	BEFORE	AFTER	BASIS
1	Blocker + Critical open	441 identified	9 open (1 Blocker, 8 Critical)	computed from the file
2	Closed, overall	0	714 = 85.4% (open pipeline 122: 112 with an open status + 10 blank)	computed from the file
3	Monthly arc	Jun 271	Jul 65 · Aug 21 · Sep 14 · Oct 4 (−98.5%)	computed from the file
4	Building slice	42 rows, 27 B+C	39 closed (92.9%); open 3, 0 B+C	computed from the file
5	Locus-side rows	86 = 10.3% of the book	86 closed; 65 B+C = 75.6%	computed from the file

Table 4 — the dollars, every multiplication shown.

STEP	QUANTITY	FORMULA → SUBSTITUTION	BASIS	VALUE
1	Triage effort, the whole book	`836 × 0.5 h = 418 h; 418 × $110 = $45,980`	30 min per row all-in (illustrative); $110/h blended (modeled, as S5/U5)	≈$46.0K
2	A week of benefit	`$1.65M ÷ 52 = $31,731`	S2's modeled recurring benefit	≈$31.7K/wk
3	Break-even	`$45,980 ÷ $31,731 = 1.45 weeks`	the log pays back if it prevents ~1.45 weeks of slip	≈1.45 weeks
4	The June spike alone	`271 × 0.5 h = 135.5 h; × $110 = $14,905; ÷ 40 = 3.4 FTE-weeks`	same assumptions	≈$14.9K
5	The building slice	`42 × 0.5 h = 21 h; × $110 = $2,310`	same assumptions	≈$2.3K

SOLUTION FLOW — THE SYSTEM & DATA MAP

```
issues log (836 rows × 19 cols)  — one table, one grammar
   status A→F · priority 0→4 · operation · functional area · owner · date
      |
      +--> weekly two-block review (30 IT / 30 business): Blocker+Critical rows first
      |        every red row: a name and a date;  'parking lot' = decided-not-now, in writing
      +--> coupled build plan (~30 tracks, holiday freeze visible)  --> E2E gates 11/22 · 12/20 · 1/30
      +--> cutover runbook (343 tasks, 48,885 min)  --> 5/1 → 7/1 window
      +--> ACL request workbooks: Dev 310 · QA 255 · Perf 200 · Prod 221 = 986 rows (access gate)
building slice (Functional Area labels, exact, case-insensitive):
   dock/appointment (23): dock · dock/office · dock/receiving lanes · dock hop · shipping dock · unload ship ·
                          trouble lane · appointment · appointment creation · xdock · crossdocks
   floor/space/hardware (19): facilities · physical layout · footprint · physical · guardrail · charging · locus hardware
```

SENSITIVITY — LOW / BASE / HIGH

INPUT	LOW	BASE	HIGH
Minutes per row (triage)	15 → $22,990 (0.72 wk)	30 → $45,980 (1.45 wk)	45 → $68,970 (2.17 wk)
Building-slice definition	narrow 31 rows · 64.5% · z 1.31	base 42 rows · 64.3% · z 1.50	broad 104 rows · 66.3% · z 2.78
Monthly decay r	0.50 → half-life ≈ 30 days	0.349 → ≈ 20 days (observed)	0.80 → ≈ 94 days (would read as a plateau)
Weekly benefit	$1.1M/52 = $21.2K → 2.17 wk	$1.65M/52 = $31.7K → 1.45 wk	$2.4M/52 = $46.2K → 1.00 wk

SPOKEN STATEMENT

> "I treated the program's issues log as an instrument and read it three ways. By severity: of 836 rows, 441 were Blocker or Critical and 98% of those closed, with closure falling to 60% for Lows — so the weekly read was working on the dangerous end. By flow: Dotcom was the most severe. By month: the June go-live spike of 271 rows decayed 65, 21, 14, 4 — about a third a month — which is what a healing cutover looks like. And the part an infrastructure leader cares about: 42 rows were the building itself — dock and appointments, conveyor, aisle 45, Locus power, footprint — 64% Blocker or Critical, 39 closed, none of the three open ones severe. The statistics are directional — z of 1.5 — and the file has no close dates, so I will not claim a time-to-close. The point is that the building's problems were rows with names and dates, not a hallway conversation."

IF CHALLENGED

"Priority inflation — 52.8% Blocker or Critical isn't a priority scale."

It's a fair flag and I'd rather say it first. Two answers: the closure gradient — 99.4%, 97.1%, 75.4%, 69.7%, 60.0% — shows the scale differentiated in practice; and the book was a go-live book, 331 rows Go-Live category, where severity runs high by construction. What I would add is a monthly check on the Blocker + Critical share so inflation shows as a trend.

"Your building slice is a label grouping you chose."

Yes — so I ran three definitions: narrow 31 rows (64.5%, z 1.31), base 42 (64.3%, z 1.50), broad 104 (66.3%, z 2.78). The direction is the same in all three; only the broad one clears 2σ, and it is the loosest definition, so I call the result directional.

"Prove the Blocker + Critical bar was met at go/no-go from this file."

I can't — the file is a late snapshot with no close dates; it shows 9 B+C still open on 2025-10-01 (1 Blocker, 8 Critical), which postdates both go-lives. The go/no-go read came from the weekly review state at the time.

TWIST MAP — LIKELY LP QUESTIONS FROM THIS INTERVIEWER → THE ANGLE TO TAKE

LIKELY QUESTION (THIS INTERVIEWER)	LP	ANGLE — WHAT TO EMPHASIZE	SKIP / NEVER SAY
Tell me about a time you used data to run a program.	Dive Deep	836 rows, three cuts; the closure gradient; the spike decay r = 0.35.	Do not call it a defect fire — bugs are 115 rows.
What did you do about things nobody owned?	Ownership	17 of 42 building rows had non-IT owners; they entered the same log with a name and a date.	Do not claim I fixed the conveyor — Operations and Maintenance did.
How do you keep a shared log honest for months?	Insist on the Highest Standards	One grammar; parking lot = decided-not-now, in writing; dedupe in the rhythm.	Do not claim a time-to-close — no close-date column.
How do you report bad news?	Earn Trust	The 271-row June spike, said out loud with the decay curve.	Do not blame IT for 342 rows.
How do you decide what to defer?	Have Backbone	Eight rows typed Parking Lot; 'decided not now' with an owner.	Never say a deferral was free.

BEHAVIORAL PACK — FOUR SEPARATE 90-SECOND STAR ANSWERS, EACH FROM A DIFFERENT MOMENT OF THE STORY NEW

DIVE DEEP · AIQB Q4 **Q1. "Walk me through a big problem or issue in your organization that you helped to solve."**

The problem was that a program of about thirty build tracks was going to run on opinion, and the first fix was to count. I made one consolidated log with five fields on every row and read it three ways. By severity, 441 of 836 rows were Blocker or Critical and closure fell with severity — 99.4% of Blockers, 60% of Lows. By flow, Dotcom ran most severe. By month, the shape told me the June spike was healing: 271, then 65, 21, 14, 4. What was missing was the monthly shape itself — it was a manual read well into the program — and I filled the gap by building the arc view once I saw it, which I would now have on the wall from the first hundred rows. The result was that both go-lives read readiness from rows, with zero customer-facing incidents.

Number to land: 836 rows · 441 B+C · 271 → 4 · r ≈ 0.35 · **Pivot to NACF:** NACF launch readiness is the same instrument — doors tested, appointment slots scheduled, UPH validated — as counted rows read severity-first. · **Do NOT say:** that 836 issues means 836 defects — bugs are 115.

INSIST ON THE HIGHEST STANDARDS · AIQB Q6 **Q2. "Describe the most significant continuous improvement project that you led."**

The catalyst was that two rows describing one issue make every count lie, so the improvement was a grammar. One log, one status ladder, one priority scale, an owner on every row, and a parking-lot status that meant 'decided not now' in writing with an owner — never silently deleted. Dedupe was part of the weekly rhythm. The result is a book where any VP could open the file on a Monday and see what the team saw: 714 of 836 closed, 98% of the Blockers and Criticals, and the open tail of 122 visible and owned. I would rather defend a visible deferral than bury a blocker, and a log that calls everything priority one is where blockers hide.

Number to land: 85.4% closed · 98.0% of B+C · 122 open, owned · **Pivot to NACF:** At NACF I would run the same grammar on a launch register: one row per risk, an owner, a date, a severity. · **Do NOT say:** that the file proves time-to-close; it has no close dates.

OWNERSHIP · AIQB Q3 **Q3. "Give me an example of an initiative you undertook because you saw that it could benefit the whole company or your customers, but wasn't within any group's individual responsibility so nothing was being done."**

The building itself did not belong to the systems program, so I made it belong to the log. Forty-two rows were dock, floor, power or footprint: remove half of a conveyor, remove the west side of aisle 45 and relabel, get Locus IDF temporary power until January 6, remove the guardrail between retail and dotcom, set the large footprint as the SKU default. 17 of those 42 sat with Operations, Engineering or Maintenance, not IT. Putting them in the same log with a name and a date meant a Blocker about power had the same Monday review as a Blocker about a WMS interface. 39 of the 42 closed, and the three still open were not Blocker or Critical. The conveyor and the power were not mine; making them visible and dated was.

Number to land: 42 rows · 17 non-IT owners · 39 closed · 0 open B+C · **Pivot to NACF:** At NACF the dock, the floor and the power are launch dependencies too — they go on the same register as the systems. · **Do NOT say:** that I fixed the conveyor or the power; Operations and Maintenance did.

EARN TRUST · AIQB Q6 **Q4. "Tell me about a time when you uncovered a significant problem in your team."**

The June spike was the biggest number the program ever produced, and I said it first. 271 rows in one month — a third of the book — 239 of them Go-Live category. I put it in the Monday review the week it appeared with the shape that explained it: the January bake and Locus physical testing had given a ramp of about ninety a month, the combined go-live surfaced everything at once, and the decay afterwards — 65, 21, 14, 4 — was what healing looks like. A spike that decays fast is a healthy cutover; one that plateaus is a design problem. Because the number was in the room before anyone asked, nobody escalated a surprise, and the readiness call was made on rows.

Number to land: 271 rows · 88.2% Go-Live · decay ≈ 0.35/month · **Pivot to NACF:** At NACF the worst number in the WBR is the one to say first, with the curve that explains it. · **Do NOT say:** that the spike was a defect fire; it was the combined go-live surfacing.

SAME STORY, THREE ANGLES — DATA · CONFLICT/INFLUENCE/BACKBONE · FAILURE-LEARNING NEW

DATA ANGLE · DIVE DEEP

"836 rows, and the closure rate falls with severity: 99.4%, 97.1%, 75.4%, 69.7%, 60.0%."

Headline metric: 98.0% of 441 B+C closed; r = 0.35

Three cuts of one book — severity, flow, month. Honest limit: no close-date column, so no time-to-close; the Operation field is free text (161 rows outside five flows).

CONFLICT / INFLUENCE ANGLE · HAVE BACKBONE; DISAGREE AND COMMIT

"Well-meaning teams wanted every improvement in the release; a parking-lot status said 'decided not now' in writing."

Headline metric: 8 Parking Lot rows; Blocker + Critical first

I defended visible deferral over a buried blocker; the cost was explicit — the room's attention went to the dangerous half of the book. The disagreement was resolved by writing the deferral, with an owner, not by winning an argument.

FAILURE / LEARNING ANGLE · INSIST ON THE HIGHEST STANDARDS

"The arc — ramp, spike, decay — was a manual read well into the program."

Headline metric: shape view from month 1, not month ~6

Record do-differently: I would build the monthly shape view from the first hundred rows; the counts were always there, the picture was not. Second: 52.8% Blocker + Critical is a priority-inflation risk I should have trended monthly.

TRAP DRILLS — THE THREE NASTIEST FOLLOW-UPS, WITH NUMERIC ANSWERS NEW

"How do you know the log was the reason go-live went well, not the team?"

I don't, and I won't claim it. What the log gives is a testable statement: 98.0% of Blockers and Criticals closed and the June spike decayed at r ≈ 0.35. A team without the log could have done the same; what the log changed is that the readiness call was made on counted rows, and a surprise surfaced on a Monday.

Say: *"I can't separate the log from the team; I can show the readiness call came off counted rows and the spike decayed in line with a healthy cutover."*

"Your building-slice finding — is it significant?"

Directional only: 27 of 42 = 64.3% vs 52.8%, z = 1.50, about p = 0.13. Across three definitions the direction holds; only the broad one clears 2σ. The decision it informs is cheap — put physical rows in the same log with owners — and holds regardless.

Say: *"z of 1.5 — directional, not proven; I would act on it because the action costs almost nothing."*

"What number would have made you stop the go-live?"

One open Blocker at the go/no-go read, or a June-style spike that plateaued instead of decaying — a decay ratio above about 0.8 for two months. The first is the record bar; the 0.8 threshold is my own illustrative plateau test.

Say: *"A Blocker open at go/no-go, or a spike that stops decaying — I would call that a design problem."*

20-SECOND VERSION + NACF BRIDGE NEW

20-second version. I ran Sephora's UDC program on one 836-row issues log with one grammar, read Blocker and Critical first: 85.4% closed, 98% of the Blockers and Criticals, the 271-row June spike decaying 65, 21, 14, 4 — and 42 rows where the dock, the floor, the power and the footprint were the problem, every one with a name and a date.

NACF bridge. NACF's launch register is the same instrument. The dock rows are CAP-A in miniature — appointments created, placards printing, pallet-build positions available before the first trailer — and the footprint rows are the CAP-C input: a SKU with no footprint or CubiScan record defaults a slot size, and a wrong default is wasted cube at the 85% effective-capacity line. I would read the register severity-first, with the dock row at the top.

Question bank — likely questions for this interviewer, with a one-line answer plan ELEVATED

Behavioral and functional questions a Senior Manager of Infrastructure is likely to ask. Each plan points at a packet story or a named backup in the master packet; stories allocated to other interviewers are pointers only. Rows 13–21 are new in v2. For the LP-by-LP version with the real Amazon wording, use the Question → Story Router at the front.

#	LIKELY QUESTION	ANSWER PLAN (ONE LINE)	STORY
1	**Tell me about the most complex physical / systems change you have led in a DC.**	S2 pitch — one pool, three planning identities, two go-lives, the 98% gate; end on +15% signed and zero incidents.	S2
2	**Tell me about a migration or cutover you ran.**	S18 pitch — tolerance before mock one; 7 → 1.8 → 0.3; the RF fallback; on time, ~3% under.	S18
3	**How do you decide a program is ready to go live?**	Counted rows, not confidence: Blocker + Critical = 0; mock inside tolerance; runbook rehearsed; rollback armed; a written recommendation.	S2 / S18
4	**How do you ramp automation without hurting throughput?**	Publish the gate from the pre-ramp baseline and the incident budget; build the throttle in advance; the floor owner owns the dial; RCA before re-ramp.	S2
5	**What are your rollback triggers, typically?**	Numbers per interface: sync < 99% for 4 h; p95 > 2× budget for 1 h (S2); mismatch > 0.5% for two days; ship-confirm posting failing > 2 h (S18).	S2 / S18
6	**How do you handle a vendor slipping on your critical path (Locus RTL)?**	Escalate the week it surfaces; re-slot openly; refuse to compress UAT to absorb it; retest after the slip.	S2
7	**Tell me about a time a rehearsed contingency saved you.**	Honest fit is S18's pre-training device test: hundreds of RF devices, the date held, training +1.5 weeks, the what-if rule left behind. The master's paper-pick fallback and ≈$45K are master-only — read the S18 source-conflict box before saying them.	S18
8	**How do you exit hypercare?**	A number written before go-live: < 2 blockers/day sustained; S2 exited week 3 of 4 with new rows falling 271 → 65 → 21 → 14 → 4 a month; S18 exited week 3. A calendar exit declares victory over open defects.	S2 / S18
9	**How would you approach consolidating or launching a node in the NACF network?**	Master §3.99 opening — book of record and metric → stocks and flows → the invariant broken today (a unit sellable in two places) → staged go-lives → ramp gate → hypercare number.	Master §3.99 + S2
10	**What is the utilization impact of consolidation?**	+15% units per labor-hour signed; one pool (√2 pooling, modeled); self-transfers to zero by construction; robots at full volume week three.	S2
